The Canadian Engineer

An Engineering Weekly

OVERCOMING OBSTACLES IN RAILWAY LOCATION.

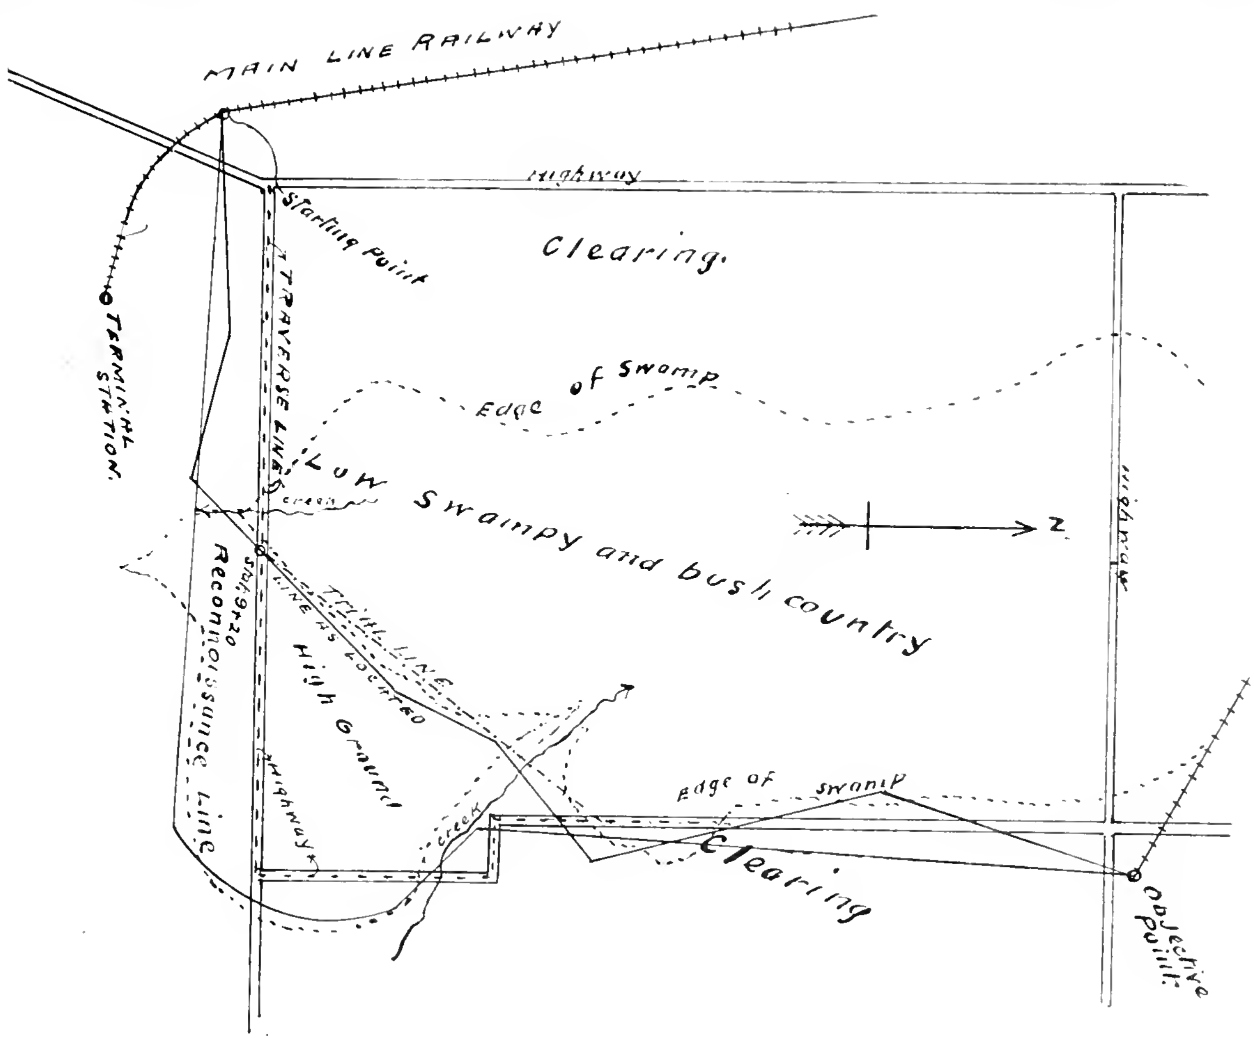
By J. A. MACDONALD.

Greater economy of cost of construction is usually required in an old, settled country than in a new and comparatively unknown one. It was required to run a line on a portion of the Intercolonial from one point to another, a distance of about three and one-half miles, as the crow flies, but over five miles by the reconnoissance route picked out, roughly, by the engineer.

by the four roads, was mostly woods, and known to be almost a solid swamp.

The instructions were to find a cross-country route, if at all feasible, rather than the long round reconnoissance route which, if a long way round, was, however, feasible.

The first thing we did was to run a traverse along the road, as shown in the plan, taking levels as we went along



The engineer had procured a fairly good map of the country, and with this map and provided with barometer, hand-level and compass, drove through the country in a horse and buggy. From the point marked "starting point" on the accompanying map he drove east along the road about two miles to where a road runs northwards towards the objective point. At the junction of those two roads was very high ground. To the left, that is the territory enclosed

and also of setts every 100 feet when we reached the higher ground. This traverse we plotted in both plan and profile. Next we proposed to run a line across through the swamp, starting at stat. 9 + 20, to ascertain the real nature of the country. It might not be as bad as expected. Off our plot we took a bearing for our trial line across the swamp. As we went along with this line we found that, to our right, the swamp ended a short distance from our tangent. Then we

took offsetts to the right as we went along with the line. This line, with the offsetts we plotted on our map, also profiles of the offsetts. In this way we had a definite and complete map of our territory. We found that we could get a good cross-country line. This we plotted out on our map and ran it, thus saving at least one and one-half miles of construction in a line only 3½ miles long as the crow flies, besides getting a line of relatively low cost, as cuts and fills were light.

This method would not, of course, answer in a new country where nothing was known of its topography, but for new work in the older, settled parts of Canada it is almost of absolute necessity. The accompanying map and plan illustrates the methods.

THE USES OF SEWAGE SLUDGE.

By H. P. Bell.

With modern methods of treating sewege the disposal of the liquid effluent is comparatively a simple matter. Since it cannot be made to serve any useful purpose and must eventually be turned into rivers or other open waters, the problem to be dealt with is that of rendering the liquid harmless and inoffensive, and this result can now be attained. The sludge—the separated solid matter—presents greater difficulties, since, although it can be made practically inoffensive, it cannot usually be allowed to accumulate in the neighborhood of cities, unless it is used for filling in land. It is, therefore, not surprising that many attempts have been made to utilize the sludge in some way and thereby to get some return for the rather large cost of handling it. No generally successful way of doing this seems to have been found, though it can be done in certain cases, where the nature of the sewage and the local conditions are favorable.

The solid matter which is usually obtained is a porous material, which retains a very large percentage of water, and two great disadvantages result from this. Firstly, the volume of wet sludge to be handled is very large in comparison with the weight of solid matter which can be utilized, and secondly, the removal of the water is a matter of considerable expense. The percentage of water is frequently as high as 90 per cent.; it may be lower with suitable methods of precipitation and separation, but is hardly ever less than 75 per cent. The greater part of this water must be removed before the material can be of any use.

In China and Japan crude sewage is spread over the fields as a fertilizer, and in China enormous quantities are conveyed for the purpose from the large cities, usually by boats on canals, with which the country is so well provided. The practice is probably very ancient and seems to be effective enough under eastern conditions. Sewage, however, not only has a low value as a fertilizer, but tends to clog the pores of the soil, owing to the great quantity of fine suspended matter which it contains. This difficulty can be got over in the east, where, with a good supply of cheap labor for hand cultivation, the soil can be continually broken and turned over. Experiments in the same direction which have been made in Europe have not given satisfactory results, and in western countries, apart from the necessity of rendering the sludge inoffensive, it must be dried off before it is of any use for agriculture. Even then, its value as a fertilizer is so low that the material can hardly ever be worth the cost of transport to any distance, though it may be worth mixing with richer fertilizers, where suitable conditions are to be found locally.

The use of the sludge as a fuel has been recommended and tried, and may be practicable where plant is in use for producing heat and power by destruction of town refuse; the sludge may also be mixed with coal for use in gas producers. Illuminating gas has been made by heating sludge in retorts, but the cost of manufacture is said to be high in proportion to the value of the gas. For any such purpose the sludge must be dried till it contains only about 25 per cent. of water. The calorific value of the completely dried material is only about half of that of good coal. To produce one pound of sludge dried by heat to 25 per cent. of moisture would take about a quarter of a pound of good coal or more than half a pound of the dried sludge itself.

The recovery of grease from sewage may prove sufficiently profitable, at any rate in places where the sewage contains a fairly high percentage of grease. Among such places are those where the working-up of raw wool is carried on on a large scale. Until lately, the methods of recovery usually took the form of extraction by solvents, such as benzine, etc., and apart from the cost of the solvents, the process was rather troublesome and expensive. A method of driving off the grease by means of steam has been introduced in England by Dr. Grossmann, and is said to give good results; it was referred to recently in The Canadian Engineer.

Two other methods of utilization may be worth mentioning. In one case the sludge is mixed with clay for making bricks, and this seems to be more particularly applicable to sludge which has been precipitated by means of lime. In the other case the sludge is used for briquetting coal dust. In both cases the value of the sludge consists in its plasticity. When incompletely dried the sludge is usually a tough and rather rubber-like material and may well serve to give plasticity to a poor clay.

Most large cities which are on or close to the sea make no attempt at utilization of their sewage sludge, which is carried out to sea and dumped in deep water. London, for instance, keeps a fleet of hopper barges for this purpose. At inland places, where the difficulties of disposal are much greater, there seem to be better chances for some kind of utilization, but it is likely that whatever is done in this direction will be done on account rather of local necessities than of any value which may be got from the results.

ONTARIO'S GOLD RESOURCES.

Gold bullion was produced at fourteen properties in Ontario last year, from none of them in large quantity. The principal contributor was The Canadian Exploration Company at Long Lake. At Porcupine the Hollinger and Vipond mines operated small test mills previous to the fire, and the Dome recovered considerable gold in the laboratory. Other producers were the Kenora (formerly Mikado) and Olympia, both at Shoal Lake; St. Anthony (Sturgeon Lake); American Eagle and Detroit Syndicate, in Munro township; Gold Pyramid, in Guibord township; Swastika; Havilah (formerly Ophir); Dr. Reddick (Larder Lake), and the Tingley prospect (Pelican Lake). The number of men employed at the foregoing mines was 597, to whom wages were paid amounting to $442,519. It is evident from these figures that most of the labor was employed in development and construction work, is Mr. T. W. Gibson's summing up in the twenty-first annual report of the Ontario Bureau of Mines.

The revival of interest in gold mining caused by the discoveries at Porcupine and the developments now under way there has put new life into a number of the older fields, which for years have lain dormant.

SPECIFICATIONS FOR ROADS OF DIFFERENT TYPES.

The following specifications are those used by Chief Engineer E. A. James, of the Board of Highway Commissioners of York County, Ontario, on the roads being built under his design and supervision throughout the county of York:

Specifications for Dolarway Pavement.

PREPARATION FOR THE ROAD BED.

1. All streets, prior to laying the pavement thereon, shall be graded as directed by the Engineer. After excavating the sub-grade unless the Engineer deems the natural ground a proper foundation, excavation shall be continued until solid ground is reached and then refilled to sub-grade with sand, cinders, gravel or broken stone.

2. When the street shall have been graded and shaped to its proper form, it shall be thoroughly rolled with a roller weighing not less than six tons, to a thoroughly compact surface. If the ground is wet, cinders, sand or gravel are to be put on before rolling.

3. Any depression discovered after this rolling shall be filled to sub-grade, re-rolled, and this repeated until a roadbed perfect as to grade and form shall have been made.

4. When the use of the roller is impracticable, the foundation must be thoroughly puddled and rammed until compacted to the satisfaction of the Engineer.

CONCRETE FOUNDATION.

5. Upon the sub-grade thus formed shall be placed a layer of Portland Cement Concrete seven inches thick to be made as follows:

The concrete for the base shall be so proportioned that the cement shall overfill the voids in the fine aggregate by at least five (5) per cent., and the mortar shall overfill the voids in the coarse aggregate by at least ten (10) per cent. The proportion shall not exceed one (1) part cement to eight (8) parts fine and coarse aggregates.

When the voids are not determined the concrete shall have the proportion of one (1) part cement, two and a half (2½) parts fine aggregate and four (4) parts coarse aggregate.

The method of measuring the materials for the concrete, including water, shall be one of which will insure separate uniform proportions at all times. A bag of cement (94 pounds) shall be considered to have a volume of one (1) cubic foot.

6. The gravel to be free from clay or other injurious material and shall contain no stone over two and one half (2½) inches in diameter.

7. If broken stone is used for concrete it shall be of the best quality of limestone, or other stone equally good, and shall be broken to such a size that the fragments shall not be larger than will pass through a 2½-inch ring and not smaller than ½ inch in its longest direction. It shall be free from dust, dirt, loam or other injurious material and shall be screened when necessary to remove dust and small particles.

8. The cement used in the work will be submitted to the tests approved and recommended by the Canadian Society of Civil Engineers, and any Cement failing to comply with these requirements, shall be rejected. All Cement used in this work shall be suitably protected from exposure to moisture until used.

9. After the sand and cement have been thoroughly mixed dry, in a mixer approved by the Engineer, enough water shall be added to produce a mass that will settle in place without tamping and not so thin that water will show on the surface.

10. Extreme care should be taken that the sub-grade is kept moist while this concrete is being put in place.

11. No re-tempering of concrete will be permitted, and that in which mortar has begun to set, shall be rejected.

12. No concrete shall be laid when the temperature at any time during the day or night falls below thirty five (35) degrees above zero, Fahrenheit.

13. Suitable Expansion Joints shall be provided at each curb line and at points every fifty feet across the roadway. The transverse joints shall not exceed three-quarters of an inch in width, and the longitudinal joints shall be one inch in width. These joints shall extend the entire depth of the pavement and be filled with DOLARWAY BITUMEN and fine sand. Great care shall be taken to fill these joints flush with the surface of the pavement, before the wearing surface is applied.

WEARING SURFACE.

14. After the concrete has been laid as above specified, and is perfectly clean and dry, there shall be spread over the entire surface a layer of DOLARWAY BITUMEN, using not less than one-third of a gallon to the square yard, said bitumen to be applied at a temperature of not less than 175 degrees Fahrenheit or more than 200 degrees Fahrenheit.

Immediately following the spreading of the Bitumen there shall be spread over the entire surface a uniform layer of dry, clean granite, trap or other approved rock screenings, using not less than one (1) cubic yard to one hundred and fifty (150) square yards of surface. No bitumen shall be applied when the temperature is below 40 Fahrenheit and the screenings shall be applied while the bitumen is sufficiently soft for the sand or screenings to be imbedded in it and unite with it. After the screenings are spread, the street shall be closed to travel for a period of not less than two (2) hours, after which the street may be opened to travel.

PATENTS:

15. All fees for any patent invention, article, agreement, or other apparatus that may be used upon or be in any way connected with the construction, erection or maintenance of the work, or any part thereof, embraced in the contract or these specifications, shall be included in the price stipulated in the contract for said work, and the contractor or contractors must protect and hold harmless the Corporation against any and all demands for such fees or claims. At least two trademark plates for every 200 lineal feet or less of pavement shall be set by the Contractor at conspicuous places in the pavement.

16. The contractor shall furnish a satisfactory surety bond guaranteeing the maintenance of the pavement during the period of three (3) years from and after the date of completion of the same. The maintenance, however, shall not include any damage to the pavement or to the foundation thereof, or to any of the damage items of work embraced by the contract, which may be incurred by action beyond the control of the contractor.

SPECIFICATIONS FOR BRICK PAVEMENT WITH CONCRETE FOUNDATION

CONCRETE FOUNDATION.

Preparing sub-grade.—The sub-grade is to be formed to the levels and cambers shown on sections; where the ground is soft or otherwise unsuitable it shall be removed and refilled with gravel, broken stone or other approved material, the whole sub-grade shall then be thoroughly rolled with a roller weighing at least eight tons, any depressions discovered after this rolling shall be filled with approved material and re-rolled until brought to the proper levels and camber.

Filling in embankments must be applied in layers of eight (8) inches in thickness and each layer thoroughly rolled.

Tile drains shall be placed under the edge of the concrete or in such places as shall be directed by the Engineer.

Concrete foundation.—When the sub-grade has been completed a layer of Portland Cement Concrete 5 inches thick shall be placed.

The broken stone for the concrete shall be hard quality limestone, free from all refuse and foreign matter, with no fragment larger than will pass, in its longest dimensions, through a 2½-inch ring, and not smaller than half an inch in its longest dimensions.

The sand is to be clean sharp sand and free from clay or other injurious material and to be thoroughly dry when first mixed with the cement.

The cement used shall be an approved brand of Portland Cement, and will be submitted to the tests approved and recommended by the Canadian Society of Civil Engineers, and any cement failing to comply with these requirements shall be rejected. All cement used in this work shall be properly protected from moisture until used.

The water used for mixing the concrete shall be reasonably clean, free from oil, sulphuric acid and strong alkalies. The cement and sand are to be first thoroughly mixed in a dry state until the whole mass shows an even shade, sufficient water shall be added to produce a plastic mass, fluid enough to settle in place without tamping, but not so thin that water will show on the surface. The broken stone must be damped before being added to this mixture, the whole mass to be thoroughly mixed or turned over at least three times, so that every fragment is coated with cement mixture.

The concrete shall be so proportioned that the cement shall overfill the voids in the sand by at least 5 per cent. and the mortar shall over-fill the voids in the stone or gravel by at least 10 per cent. The proportion shall not exceed one part of cement to eight parts of the other materials. When the voids are not determined the concrete shall have the proportions of one part of cement to three parts of sand and five parts of stone. A sack of cement (94 pounds) shall be considered to have a volume of one cubic foot.

The concrete shall be laid while fresh and within twenty minutes after it has been laid it shall be struck off with a template, and as soon as practical trowelled sufficiently to bring the finer particles to the surface and then broomed. When the surface is finished it shall be kept wet for seven days. Care should be taken that the sub-grade is kept moist while this concrete is being put in place. The whole of the concrete must be thoroughly tamped and no re-tamping will be permitted. No concrete shall be laid when the temperature at any time during the day or night fall below 35 degrees above zero Fahrenheit.

Expansion joints shall be provided at each curb-line and at points every 25 feet across the roadway. The transverse joints shall not exceed three-quarters of an inch in width and the longitudinal joints shall be one inch in width. These joints shall extend the entire depth of the pavement and shall be filled with asphaltic paving cement; great care shall be taken to fill these joints flush with the surface of the pavement, and that no dirt, stone, etc., be left in the joints.

SAND CUSHION.

On the concrete foundation shall be spread a ¾-inch cushion of clean sand, free from loam and foreign matter, and sufficiently fine so that it will pass through a (¼) one-quarter-inch mesh; the sand must be spread by means of a template made to conform to the true curvature of the street cross sections, the compression to be done with a hand roller weighing from three hundred to four hundred pounds.

BRICK PAVING.

The bricks used for paving shall be sound, well-burnt paving bricks, showing at least one fairly straight face, free from cracks and excessive laminations, preferably made from shale. They shall be not less than 2½ in. x 4 in. x 8 in., or more than 3¾ in. x 4 in x 9 in., and shall not vary one-fourth (¼) of an inch in width or depth or more than one-half of an inch in length. The brick shall be reasonably perfect in shape, free from marked warpings or distortion. The bricks shall be carefully laid on edge, with best edge uppermost, as compactly as possible, in straight course across the street, with the length of the bricks at right angles to the axis of the street. Whole bricks only shall be used, except in starting and finishing courses, all fractional batting to be next to the curbs.

Expansion joints shall be provided at each curb line and at points 25 feet apart across the roadway. The transverse joints shall not exceed three-quarters (¾) of an inch in width, and the longitudinal joints shall be one inch in width. These joints shall extend the entire depth of the pavement, and shall be filled with asphaltic paving cement; great care shall be taken to fill these joints flush with the surface of the pavement and that no dirt, etc., be left in the joints.

After 25 or 30 feet of the pavement is laid, every part shall be rammed with a heavy rammer, a plank laid on the surface parallel to the curb to receive the blows of the rammer, or a steam roller not to exceed five tons may be used. When a steam roller is used it shall first be passed slowly back and forth parallel with the curb until the bricks are firmly imbedded in the sand cushion, the pavement shall then be rolled the entire width of the street transversely at an angle of 45 degrees to the curb, repeating the rolling in like manner in the opposite direction. All broken or injured brick must be taken up and replaced with satisfactory ones, which must be brought to true surface by tamping.

FILLER.

The filler shall be composed of one part of clean sharp, fine sand and one part of Portland Cement, thoroughly mixed dry in small quantities, water is then to be added until a mixture is of the consistency of thin cream, which shall be kept in constant motion until all used up. The filler shall be poured into the joints until it appears on the surface.

The sides and edges of the bricks shall be thoroughly wet by sprinkling before the filler is applied. Care shall be taken that the joints are free from sand, etc., before the filler is applied. After the filler has hardened, a half inch coating of sand shall be spread over the whole surface of the pavement; in dry weather this coating shall be kept damp by sprinkling for three days.

SPECIFICATIONS FOR ROCMAC ROAD

Sub-grade.—Before the base course is laid the roadbed shall be shaped to the proper levels and cross-sections and thoroughly rolled with a roller weighing at least ten tons.

After excavating the sub-grade, unless the Engineer deems the natural ground a proper foundation, excavation shall be continued until solid ground is reached and then refilled to sub-grade with sand, cinders, gravel or broken stone.

Any depression discovered after rolling shall be filled to sub-grade re-rolled and this repeated until a roadbed perfect as to grade and form shall have been made.

When the use of the roller is impracticable, the foundation must be thoroughly puddled and rammed until compacted to the satisfaction of the Engineer.

Base Course.—The base course shall consist of best quality limestone, broken so as to pass through a 4-in. ring by its longest dimensions and be retained on a 2-in. ring spread and rolled to a finished depth of four inches.

The base course shall be thoroughly rolled with a heavy roller until the surface supports the roller without yielding.

On the base course shall be spread a coating of ½-inch. limestone screenings, which shall be rolled into the interstices until a sufficiently firm surface is obtained to prevent the Rocmac matrix from penetrating the base course. If thought necessary by the Engineer, the base course and screenings shall be watered before the Rocmac is put in place.

Rocmac Matrix.—The Rocmac matrix shall be composed as follows: one-third cubic yard of limestone crushed to pass through a one-fourth web screen and containing 50 per cent. limestone dust; add to this five gallons of Rocmac solution and thoroughly mix on a mixing board into a stiff mortar and at once spread on the base course.

The limestone shall be dampened to facilitate the chemical action of the solution.

The Rocmac matrix shall be spread on a base course to a depth of 1 1/3 inches or about 1/3 cubic yard of matrix to 9 sq. yards of road surface for each additional inch of pavement 1/3 inch is added to the depth of the matrix.

Top Course.—The material for the top course shall consist of trap rock from an approved quarry, broken to pass a 2½-inch ring and be retained on a 1½-inch ring. The trap rock shall be put in place immediately after the spreading of the matrix in such quantities as will give a finished depth of 3 inches sprinkled with water and rolled with a roller weighing ten tons.

The road is to be rolled rapidly until the matrix appears on the surface, and is then rolled as slowly as possible; as the matrix rises it is to be brushed with a hand-broom so as to prevent it lying in particles.

If the stones are picked up from the road by the roller wheels the latter are to be sprinkled with water.

The roller is to be continued until the whole surface of the road is thoroughly flushed up with the matrix and supports the roller without yielding; the surface is then to be spread with a thin coating of limestone dust to absorb excess of solution and to form a cushion while the process of setting is going on.

SPECIFICATIONS FOR WATERBOUND MACADAM PAVEMENT

M. 1.—BROKEN STONE.

The contractor shall submit with his bid a written statement of the quarries, ledges or other source of supply from which he proposes to obtain the stone for the road, together with a sample of such stone weighing at least 30 pounds. If the proposed quarries are developed and a uniform product satisfactory to the Engineer can be obtained from them, this will be accepted and the contractor will be so informed. If after trial it is found that for any reason product from any source at any time proves unsatisfactory to the Engineer, he may decline to continue its use and can require the contractor to develop other quarries of source of supply, and the contractor shall have no claim for increased payment on account of such requirement. If the qualities of the sample of stone submitted are satisfactory to the Engineer and are accepted by him, the sample will be retained and all stone brought on the road inferior in character to the sample will be rejected. All broken stone used must be hard and compact and of uniform character. It must have enough cementing value to thoroughly bind the surface of the road after rolling. The broken stone shall have the rough surface of fracture, and shall be as nearly cubical as possible. It shall be free from earth or other objectional material, and screened to the required sizes. No soft, disintegrated stone shall be used.

M. 2.—DRAINAGE.

The side ditches and gutters shall have true grades and sufficient incline as provided in the plans and profile to furnish a free and uniform flow of water to the nearest natural outlets of culverts. Where natural outlets are utilized, they shall be so improved where necessary as to carry the water quickly away from the highway. The ditches must conform in all cases to the standard cross-sections for the class of road which is being improved.

SHAPING SURFACE OF SUB-GRADE AND SHOULDERS.

Before the broken stone is spread, the roadbed shall be shaped to a true surface, conforming to the cross-section of the highway, and thoroughly rolled by the steam roller. If the road shows a wavy motion after passing the roller over it three or four times, it may indicate too much moisture in the sub-grade. If on examination this is found to be the case, the rolling should be stopped, the roller moved ahead, and time allowed for the sub-grade to dry out.

M. 3.—SCARIFYING.

When called for on the plans or ordered by the Engineer, the old macadam surface shall be thoroughly scarified by hand or with a mechanical scarifier of an approved type, to the width and depth shown on the plans, after which the loose stone shall be raked to a uniform grade and crown.

M. 4.—MACADAM.

The width of the macadam shall be . . . feet, unless otherwise shown on the plans. The macadam road shall be laid in layers of courses, as follows:—

First Course.—First course shall have a thickness of four inches after rolling, and shall consist of limestone that will pass through a 4-inch screen and be retained on a 2-inch screen. No piece shall be more than four inches in length.

The broken stone in this course shall be spread evenly over the sub-grade to such a depth that they will have, when rolled, the required thickness of three inches. Each layer shall be rolled with a self-propelled roller, weighing not less than ten tons, until the broken stone shall not creep ahead of the roller and is thoroughly compacted to the satisfaction of the Engineer. Rolling must, in all cases, begin at the sides of the road and work towards the centre. Under no circumstances shall the centre be rolled first. In case the Engineer should consider it advisable, a thin course of screenings may be spread over this layer of the compressed stone and rolled. If any depressions occur during or after the rolling they must be filled with broken stone of the size that has been used in the course and re-rolled until a firm, even surface is obtained and the course has the required thickness. The Engineer may at any time during the laying of the broken stone require the roller to be operated sixteen hours each day, and the contractor must provide the extra shift operators when so required.

With certain rocks it has been noted that after the roller passes over them a few times, they fail to compact and the sharp edges are broken off. A slight sprinkling of sand or stone screenings or water may prevent this. One after another of these should be tried until the work progresses to the satisfaction of the Engineer. In the case of heavy fills, the roller must not be run to the outer edge of the shoulders unless the fill has had time to settle. The roller should be worked out slowly under these conditions.

Second Course.—The second course shall have a thickness of three inches after rolling, and shall consist of granite stone, which shall pass through a two-inch screen and be retained on a three-quarter-inch screen. No piece shall be more than two inches in length. Broken stone shall be placed and spread, as specified for the first course, and spread to such a depth that it will have when rolled the required thickness. Second course shall be rolled with a self-propelled roller weighing not less than ten tons, until it is completed to form a firm, smooth surface approved by the Engineer. Rolling must in all cases begin at the sides of the road and be worked towards the centre, and care be taken to preserve the grade and the crown of the road. If any depressions occur during or after the rolling they must be filled with broken stones of the size specified for the second course and re-rolled until a firm, even surface conforming to grade and cross-sections is obtained.

M. 5.—WATER-BOUND MACADAM SCREENINGS.

After the two courses above described are thoroughly compacted to the satisfaction of the Engineer in charge, broken limestone screenings that will pass through a three-quarter-inch screen and containing dust of fracture shall be spread in a thin layer over the course of stone and sprinkled sufficiently to wet it thoroughly, but not so much as to saturate the foundation, then rolled and more screenings applied, sprinkled and rolled, until the voids in the course of stone is just covered. Each application of screenings shall be sprinkled until hard and smooth to the satisfaction and acceptance of the Engineer in charge. Screenings shall be applied from piles at the sides of the road, sprinkled from wagons or carts and shall not be dumped on the sub-grade nor upon the layer of course stone in advance of the final surfacing. The Engineer will not permit any travel upon the layer of screenings before rolling. The binder course in all cases must only be sufficient to completely fill the voids and just cover the course of stone after it has been rolled separately and evened up with stone of the same sizes as have been used in that particular course. During final rolling of macadam the earth shoulders outside of the macadam shall be thoroughly compacted by rolling and sprinkling. Any part of macadam that cannot be reached by the roller shall be thoroughly tamped by hand rammer.

M. 6.—GRAVEL SHOULDERS.

Where directed by the Engineer gravel that will pass an 1½-inch ring and composed of hard, durable stone and assorted sizes of finer materials sufficient, but not more than sufficient, to fill the voids, and shall be three inches thick after rolling.

It shall be sprinkled until thoroughly wet and rolled with a self-propelled road roller weighing approximately ten tons until smooth and thoroughly consolidated.

M. 7.—SHOULDER DRAINS.

Shoulder drains shall be constructed according to the plans, on either side of the roadbed, where found necessary by the Engineer.

M. 8.—METHOD OF CARRYING ON WORK.

This improvement shall be started at the end of the road farthest from the source of supply of the broken stones, unless otherwise ordered by the Engineer. All courses of stone shall be carried along as nearly together as practicable. Each course, after being spread, shall be promptly rolled and covered with the next course as soon as possible. No allowance or extra compensation will be made for material driven into the sub-grade, or for mistakes made by contractor in preparing sub-grade.

Before the road will be finally accepted the broken stone surface must be hard, smooth, regular and well-balanced. The shoulders must be rolled down to grade with the required slope to the ditches and thoroughly compacted. Side ditches must be brought to an even grade and provided with outlets as directed by the Engineer, and must be clear of all obstruction.

M. 9.—HIGHWAY INTERSECTIONS AND DRIVEWAYS.

At all highway intersections, private driveways or entrances macadam shall be carried ont to full width of the roadbed, at least twelve feet from the centre line, as specified or shown on the plans or as directed by the Engineer in charge.

M. 10.—ROLLING.

Include all rolling necessary to thoroughly compact the sub-grade and broken stone, and in finishing and binding the road.

M. 11.—SPRINKLING.

Include all sprinkling with water required by the Engineer in the construction and finishing the road.

M. 12.—ALTERNATE BIDS.

In each case where an alternate bid is snbmitted such bid must be accompanied by drawings, cross-sections and a complete description of the materials used and the method of construction employed in building the same. Each alternate bid must further contain the following clause written into such bid:

The prices stated in this tender and stipulated in the contract must be understood to cover every contingency, the furnishing of all labor, materials, power and plant which may be required for the performing and completing of the work described in these specifications and for maintaining same in good order for a period of one year from date of acceptance of the work by the Board of Highway Commissioners for York.

M. 13.—

The work must proceed as rapidly as conditions will allow and not less than 500 lineal feet per week must be completed.

WIDTH OF TIRES.

With the growth of Toronto, the interurban and suburban traffic on our highways has increased, and, with the increase, in the volume of traffic, there has been an increase in the tonnage carried per inch of tire.

Narrow tires carrying heavy loads have a very destructive effect upon the road surface, while wide tires from the point of view of maintenance are desirable. The concentration of the heavy load on a narrow tire has the effect of cutting the road surface, while the same load on a sufficiently wide tire would act as a roller and on improved roads it would be even better if the front end and rear wheel did not track. Wide tires must not be carried to excess, for we will find on a well-crowned road a tire of 5 inches in width would only come partly in contact with the road and the load would be carried on one edge of the tire and the same cutting effect will occur as with a narrow tire.

The wide tire is a distinct disadvantage on bad roads, so that (under present conditions) with a few improved and many unimproved roadways, the question of narrow vs. wide tires is one that will require careful consideration.

If improved roads are to be cheaply maintained there must be a ratio fixed between the width of tire and the load carried for at the present time our roads are requiring to take traffic which is extremely injurious.

The steamship "Vanellus," the latest addition to the fleet of the Cork Steam Ship Company, Limited, Cork, sailed from the Tyne on Tuesday, the 10th inst., on the completion of a very successful trial trip.

The steamer has been built and engined at the Neptune Works of Swan, Hunter & Wigham Richardson, Limited. She is 285 feet in length by 38 feet beam, and carries over 2,700 tons deadweight on 19½ feet draft. She has been constructed to attain the highest class in Lloyds' Register, has accommodation for a few passengers, and is in every way a cargo steamer of the highest class.

Her propelling machinery, which consists of a set of triple expansion engines, supplied with steam by two boilers, and the whole of which have been constructed at the Neptune Works of Swan, Hunter & Wigham Richardson, Limited, worked on the trial trip without the slightest hitch, and gave satisfaction to all concerned, driving the vessel at a speed of over 12 knots per hour.

The owners were represented on the trial trip by Capt. Hore, of Liverpool, their marine superintendent, and by Mr. Flockhart, of Liverpool, their superintendent engineer. After the trial trip, the vessel sailed to take up her station in the company's service between Liverpool, Manchester and Dutch and Belgian ports.

THE BRIDGE OF THE CANADIAN PACIFIC RAILWAY AT LACHINE, P.Q.

In connection with the double tracking of the Canadian Pacific Railway it became necessary to change the bridge which crosses the River St. Lawrence at Lachine, and which is located about two miles above the Lachine Rapids, from a single-track structure to accommodate the double tracks. Some months ago the engineers began the preparation of plans for the widening of the bridge. In order to effect this work it was necessary to change the old structure to a great extent. In the issue of *The Canadian Engineer* of January 18, 1912, the work of enlarging the old piers, which was undertaken by the Foundation Company, of Montreal, was described.

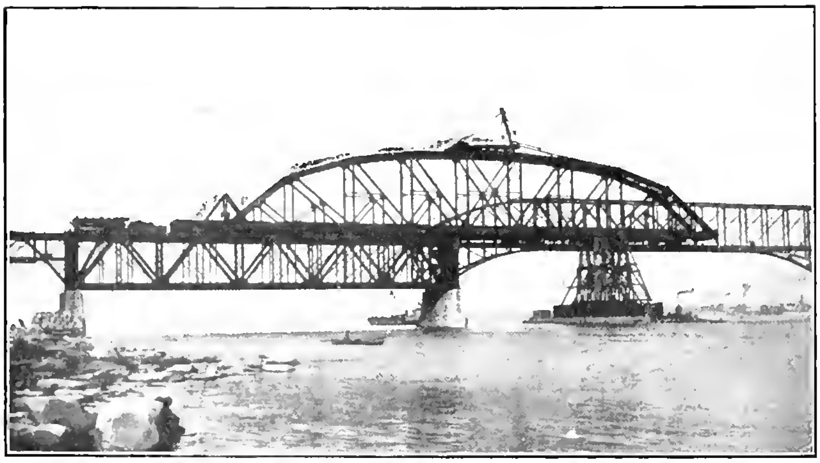


Fig. 1.—Floating One of the New Spans into Position.

It was on July 12, 1910, that the first operation was made on the enlargement of the old piers to carry the new girders before any of the new steel could be swung. This in itself was a huge job, and the Foundation Company undertook to complete the first eleven piers during the first season. However, this was not accomplished, but was completed by November 8, 1911, leaving only one pier on the up-stream side to be finished when the cantilever is taken out. The work on the superstructure was commenced on March 15, 1911, when the placing of the two eighty-deck plates was first undertaken.

The bridge, when completed, will have a total length of 3,138 feet, consisting of six 80-foot deck girder spans, two 122-foot deck truss spans, fourteen 120-foot 8-inch deck truss spans, eight 238-foot 6-inch deck truss spans, four 268-foot 4-inch deck truss spans, four 405 foot 7-inch through truss spans, two 119-foot 2-inch deck truss spans.

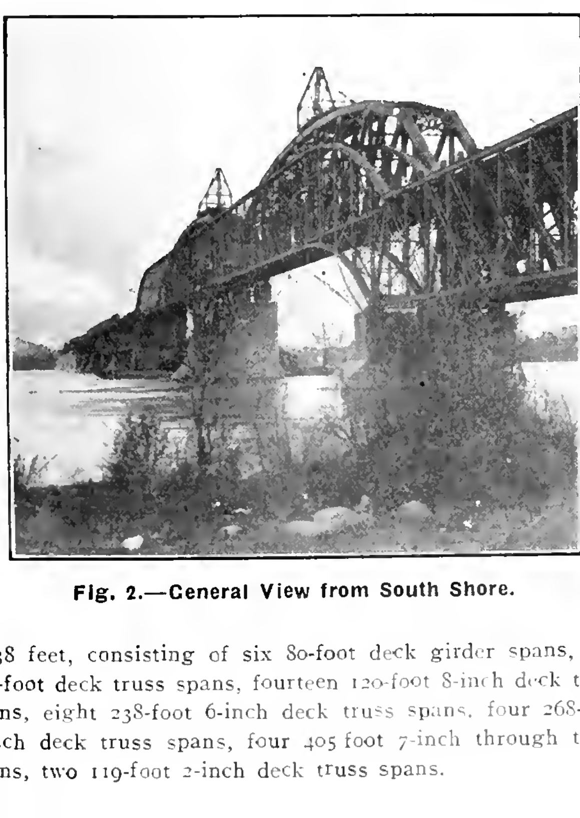

Fig. 2.—General View from South Shore.

The erection of steel was begun at the Highlands end, and by working from the old bridge the new spans for the second track east of the old track were placed out to pier No. 7. By sliding the old 240-foot span and the two new 120-foot spans between piers 6 and 7 it was possible to place a crossover about at pier 6 and turn the traffic over the new east track from that point to the shore. The old structure under the west track was then removed between pier 6 and the shore and the new superstructure placed. The erection of the east half between piers 7 and 12 was then completed and a crossover between piers 11 and 12 was made by slewing the outer end of these two spans so that the new span connected the east side of pier 11 with the west side of pier 12. Traffic was then turned over the east track between pier 12 and the Highlands shore, and the old structure between piers 7 and 12 was dismantled and the new spans were placed. The approach span on the Caughnawaga side between piers 14 and 15 was completed about the same time as the eastern spans between piers 7 and 12, and when traffic was turned over the west track between pier 12 and the Highlands shore the new through truss channel spans for the east track were erected over the deck approaches on either side. The channel spans will be pushed out to place by mounting the back ends on rollers so they can slide over the approach spans, the front ends being carried on scows floating in the river. When these spans are in position, traffic will be turned over this track for the entire length of the bridge, while the south approach span and two channel spans on the west track are

Fig. 3.—View Showing Old and New Spans from the South End.

placed. It is expected that this work will require several months to complete.

It is interesting to note that in the new bridge there are no less than 8,072,252 lbs. of steel. The eight-ft. lengths run 110,000 lbs., the 120's 226,000 lbs., the 240's 960,000 lbs., the 270's 1,324,138 lbs., and the 480's 2,600,000 lbs.

Fig. 1 is taken from a photograph secured while one of these large spans was being floated into position.

The spans were erected at the yards of the Dominion Bridge Company, which are in close proximity to the bridge, connected by a spur line, and as soon as finished were re-erected on the finished deck plate portion of the bridge on the Caughnawaga side of the stream, where space sufficient in length had been left for the purpose.

Fig. 2 shows the old and new spans and it is made from the south end. A view of the entire work from the south shore is shown in Fig. 3.

The design of the new bridge was made under the supervision of Mr. P. B. Motley, engineer of bridges, Canadian Pacific Railway, and the construction work is being supervised by Mr. J. H. Barber. The Foundation Company, of Montreal, built the piers and furnished the equipment on the deep-water piers. The equipment for the piers in shallow water was furnished by the C.P.R., and the work was handled by their men. The Dominion Bridge Company, of Montreal, fabricated and erected the steel superstructure.

BITUMINOUS PAVEMENTS FOR CITY STREETS.*

By George W. Tillson.†

The first asphalt pavement of any quantity in this country was laid in 1877 on Pennsylvania Avenue, in Washington, and since that time it has been in general use all over the country. In 1890 in the eight cities of Boston, Brooklyn, Buffalo, Chicago, New York, Philadelphia, St. Louis and Washington, there were 246 miles of asphalt pavement. So great was its popularity that in these eight cities in 1911 there were 2,348 miles.

The hard asphalts have undoubtedly been formed by natural distillation of oils. In the refining of the petroleum oils of California, however, it was discovered that after evaporating the volatile oils an asphalt residuum was obtained. These California oils are different from the Ohio or Pennsylvania petroleums, as these latter, when distilled, produce paraffine rather than asphalt; consequently the Eastern oils are said to have a paraffine base while the California oils have an asphaltic base. Similar oils also have been discovered in Texas, Mexico and on the Island of Trinidad.

The natural asphalts are too hard for direct use in pavements and must be fluxed with some softer material, either an asphalt or a paraffine flux. This mixture of asphalt and flux, after it is prepared for the pavement, is known as asphaltic cement, and as this is the material to be actually used it has been thought by many that specifications for asphalt should specify tests for the asphaltic cement without any regard for the asphalt itself. In the present stage of the industry it would seem to the writer that this is hardly a safe proceeding. A natural, hard asphalt may possibly be fluxed with a certain material so that it will make an asphaltic cement that will be satisfactory in every way at the time it is made, but when laid upon the street and subjected to the action of the atmosphere the lighter parts of the flux may volatilize, so that the pavement will crack badly.

Construction of Pavement.—It is assumed that the pavement is laid upon a stable foundation. This is an important feature in all structures, and particularly so in an asphalt pavement, as the asphalt is simply a carpet, the foundation being the floor which must sustain the actual load. The wearing surface proper is made up of asphaltic cement, sand and mineral dust. The sand is really the wearing part of the pavement, the function of the asphalt being simply to hold the particles of sand together and of the mineral dust to supplement the sand by partially filling its voids so that when mixed with the sand and the asphalt the mixture will be as dense as possible. This is necessary not only to obtain a surface that will best resist the action of traffic, but also to prevent the absorption of water, which would cause disintegration and decay.

There has always been more or less discussion as to the size of the sand to be used. The following classification, it is believed, would produce a first-class pavement, other conditions being satisfactory.

Per Cent. Composition of Standard and Permissible Asphalt Pavements.

	Standard Heavy.	Limits.	Standard Light.	Limits.
Bitumen	11	10.5—12.5	10	9.5—10.5
Passing 200-mesh ...	12	10 —14	10	8 —12
Passing 80-mesh ...	26	22 —30	12	10 —14
Passing 40-mesh ...	34	30 —38	38	34 —42
Passing 10-mesh ...	17	14 —20	30	26 —34
Penetration 77° Fahr.	45	40 —55	65	55 —75

The relative proportions of the asphaltic cement and the sand and dust to be used will depend upon both the character of the sand and the asphaltic cement and the traffic of the street, as well as climatic conditions. The refined Trinidad asphalt contains approximately 55 per cent. of bitumen, Bermudez asphalt 95 per cent., and the oil asphalts generally 99.5 per cent., and the flux can be considered as being 100 per cent. bitumen. It will be seen that a cement made of these different materials will contain different amounts of bitumen, and consequently different amounts of cement must be used in order to produce a certain amount of bitumen in the pavement, and this is generally stipulated in the specifications. This amount varies from 9.5 to 12.5 per cent., according to general conditions.

In the construction of an asphalt pavement there are two points upon which the practice does not seem to be uniform in the different cities. One is the treatment of the gutter and the other the area adjacent to the street car tracks. Many cities lay a gutter of brick, or stone. While there is no question that a stone or brick gutter is more durable than one of asphalt, it has generally been the practice in the borough of Brooklyn to lay the asphalt up to the curb; in no case has the cost of repairing the pavement in the gutter exceeded the average on the street surface enough to make it necessary to lay the more permanent gutter. The same difference in practice applies to the treatment of the area adjacent to the rails of the street car track, and here the Brooklyn practice has been to lay the asphalt up to the rails themselves without any intervening material. If the tracks are laid in the most approved modern way there is no objection to laying the asphalt up to the rails. On a railroad street the best possible construction, where asphalt is to be used, is to lay the asphalt from the curb to the tracks and pave the remainder of the street with brick, wood or smooth stone blocks. With a modern grooved rail and proper construction pavement can be so laid that traffic will pass across

* Abstract of paper delivered to American Road Builders' Association, at Cincinnati, December 3 to 5, 1912.

† Consulting Engineer to the Borough President of Brooklyn, New York.

the tracks from one side to the other with no appreciable interference.

Maintenance and Repair.—In Brooklyn a municipal plant has been in use for five years, and the cost of repairing all of its asphalt streets out of guarantee has been 3.68 cents per square yard per year. As an indication of the effect of street car tracks upon the wear and tear of pavements, it should be noted that in 1911, in Brooklyn, the cost on street car track streets was 6.5 cents per square yard, while on streets without car tracks it was but 2.9 cents. In Buffalo, where probably a larger amount of asphalt has been kept in repair than in any other city, the cost for maintaining 43,000,000 square yards, scattered over a term of years, has been 3.78 cents per square yard. In this city the repairing is done by contract, the contractor being paid a unit price per square yard for work actually performed. In Toronto, Canada, repairs made with the municipal plant cost 77 cents per square yard of pavement actually laid, while in Detroit, which also used a municipal plant, the work cost $1.06 per square yard during the past eight years.

Life of an Asphalt Pavement.—In a careful analysis of the results of the work in Buffalo for many years Mr. H. Norton, deputy engineer-commissioner, deduces that the average life is 20 years. Officials of the city of Washington also estimate the life to be 20 years under ordinary conditions. The writer has generally taken the life to be 18 years.

In studying this subject during the past season the writer obtained from the cities of Buffalo, Rochester, Washington and the borough of Brooklyn, New York City, the cost of keeping their different pavements in repair for the successive years out of guarantee, the rule being applied to those pavements where the guarantee had been for five years. The costs in Washington have been applied to streets that have been laid 33 years. For the first year out of guarantee the pavement cost 2 cents, for the second year about the same, running up to a little over 4 cents the third year, gradually increasing to a little over 5 cents in the eighth, then decreasing to 4 cents in the eleventh, and running in a fairly uniform line to the nineteenth, when they reached 6 cents, and then gradually reducing to 2 cents in the twenty-eighth year. These figures refer to a large number of streets, except in the streets that have been out of guarantee more than 23 years. The strange thing is that the cost has been not more than 6 cents for any one year, and after the nineteenth year becomes less.

The records in Rochester have been kept for pavements 27 years old, in Buffalo 25 years old, and in Brooklyn 15 years old. These costs on the whole are about the same and fairly consistent with themselves, the Rochester costs being slightly less and Brooklyn slightly more than those for Buffalo.

Asphalt Block Pavement.—When asphalt blocks were first used they were made 4 in. wide, 5 in. deep and 12 in. long, but the thickness has been gradually reduced until at the present time the usual thickness is 3 in., and in some instances 2 in. for light traffic streets. The specifications which are now in use in Brooklyn, and which are probably as definite as any in the country, provide that the stone shall be trap rock as nearly cubical as possible, of a size to pass a ¼-in. sieve not less than 40 per cent. to be retained on a 20-mesh sieve and not less than 12 per cent. to pass a 100-mesh sieve. If the stone as received does not have this amount of fine material, dust is added to make the desired quantity, and in any case not less than 6 per cent. of dust shall be added. The blocks shall contain not less than 5¾ nor more than 8 per cent. of bitumen; the specific gravity of the blocks to be not less than 2.5. It is further provided that after being dried for 24 hours at a temperature of 150 deg. Fahr., the blocks shall not absorb more than 1 per cent. of water when immersed for seven days.

In bitulithic pavement the binding material is either asphalt or coal tar. The pavement is patented and it was originally intended to use coal tar, but asphalt has since been substituted to a greater or less extent. The principal idea is that the voids in the stone should be as small as possible, the materials being predetermined and apportioned by weight by elaborate machinery. The maximum size of stone used is approximately 1 in. in diameter, and on this account the pavement can be laid on steeper grades than the sheet asphalt. The first pavement of this character was laid in Pawtucket, R.I., on a 7½ per cent. grade, and the engineer of that city says that no trouble whatever has been caused by slipperiness. Up to February, 1912, about 20,000,000 sq. yd. of this pavement had been laid in this country.

ROAD BUILDING AT A MILE-PER-DAY RATE.*

By C. Howland Leavitt.†

During the last four months 102 miles of highways in the borough of Queens, New York City, have been resurfaced at an average rate of 10,000 sq. yd. daily or practically 1 mile per day. The work has been done under contracts involving a total expenditure of $1,877,820.

The old macadam roads generally had good foundations, many of them, in fact, having a Telford bottom, and with few exceptions the grades are light and the drainage good, the sub-soil being sandy. In a few instances the grades ran between 5 and 8 per cent., and these sections received special attention.

The controlling features in deciding upon the character of paving to be used were: The nature of the traffic, the construction then in place which was to be used to best advantage, the first cost and the cost of maintenance. Probably 75 per cent. of the traffic is automobile. This portion of the traffic demanded a smooth pavement and one that could be kept in smooth condition continuously. The heavy horse-drawn traffic demanded a surface affording a good foothold and easy draft. For heavy grades the choice was granite block. Generally a bitulithic carpet placed upon the old macadam seemed best to meet all requirements. The first cost of a bitulithic macadam by the penetration method would have been considerably lower than a bitulithic concrete by the mixed method. Under the traffic to which these loads are subjected a light flush coat of bitumen and stone at a cost of from 10 to 15 cents. per square yard would be necessary yearly to maintain bitulithic macadam in good condition. Experience has demonstrated to us that such is the case. Adding this to first cost, as determined by actual contract cost, would bring the cost at the end of five years to about $1.25 per square yard for bitulithic macadam. We estimated that a bitulithic concrete on a properly prepared macadam foundation, including the preparation of the foundation and 5 years' guarantee, would not exceed this. The low bids as received have varied generally from $1 to $1.20 and the average for 1,396,550 sq. yd. was $1.11, including a five years' maintenance.

Owing to differences in the length of haul for materials used and also in the varying requirements as to gutters, binders, etc., the price bid varied in the different contracts. In the case of the Hoffman Boulevard, a street of unusually

* Abstract of paper delivered to American Road Builders' Association, at Cincinnati, December 3 to 5, 1912.

† Superintendent, Bureau of Highways, Borough of Queens, New York City.

heavy traffic, the price ran as high as $1.44 per square yard, while on the other hand there were a number of cases in which prices ran below $1, going as low as 86 to 91 cents in several cases.

The essential features of these specifications for a bitulithic concrete wearing surface are the requirements for the asphalt, mineral aggregate, the method of preparing the old macadam foundation and the laying of the asphaltic concrete. A high grade of asphalt was specified and materials from five different sources were used by the various contractors. About three-fourths of the entire amount used, however, was Bermudez asphalt.

The old macadam road was as lightly scarified as would permit of the reshaping of the old road to the crown desired. After shaping with rakes and forks it was then rolled and filled, additional stone being added where necessary, until the foundation was tight and compacted, to a width 1 ft. wider than the finished pavement; 2-in. planks were then drift-bolted to the foundation along the lines to which the asphalt was to be laid and the asphalt spread and raked. In rolling the rear roll was run over these planks so as to grip them, and in this way good compression was obtained on the edges; neat cement was cast over the surface after the preliminary rolling and swept with a broom so as to fill in the small voids in the surface and the rolling continued to final compression. After the removal of the planks the macadam along the edges was partly removed and bricks, generally in three courses, laid along the edge and filled with a bitulithic filler. In some instances the bricks were omitted and broken stone was used along the edges filled with screenings and thoroughly rolled in. The latter method seems to prove satisfactory where the travel is not crowded so as to compel vehicles to run along the edge of the pavement constantly. The wings of the roads were then graded to a gutter line generally from 5 to 7 ft. from the edge of the pavement.

Although the seepage into the subsoil is good, there were places where water would collect, and we took special pains to drain these places by building small basins with drains to carry off the water. Stone gutters were used wherever it was deemed advisable to prevent wash.

This work was distributed over an area of 65,000 acres, and was divided into 57 contracts. The greatest length covered by a single contract was 6.2 miles, the shortest 0.47 mile. In every case the contracts were allotted to the lowest bidder. All the asphaltic concrete contracts were identical as to form, and there was a single standard set of specifications throughout, which, however, provided sufficient elasticity to be adaptable to any conditions of the old roads.

Portable plants of several different types, all working on the same principle as the permanent asphalt plants, were used, in addition to three permanent asphalt plants. The Continental Public Works Company used a semi-portable plant, consisting of high-speed engine and locomotive boiler; sand-heating devices consisting of an American process driver 30 ft. long, 4 ft. in diameter, jacketed with asbestos and equipped with a Dutch oven with fuel oil burner attachments; a mixing unit consisting of an inclosed hot sand bucket-elevator, sand screens, sand hoppers with the necessary bins for the separation of the mineral aggregate, measuring boxes and a 6-ft. asphalt mixer. The usual asphalt kettles of about 1,000 gal. capacity were used. In this particular plant fuel oil was used both in the heating drum and in the boiler with excellent results. This plant had a maximum capacity of about 1,500 sq. yd. of 2-in. asphalt concrete per 8-hour working day.

The Barber Asphalt Paving Company on a portion of its work used a semi-portable plant very much of the same type as the one above described. This plant, as well as several others, was equipped with the necessary compressed air fixtures to convey the asphaltic cement from the tanks directly to the mixing platform. This plant would prepare and mix enough bituminous macadam mixture to lay 1,200 sq. yd. 2 in. thick in 8 hours' operation. The other plant used by this company was a permanent asphalt plant with a capacity of about 3,400 sq. yd.

The Cleveland Trinidad Company put up a permanent plant on the waterfront. This plant has a capacity of about 3,000 sq. yd. of 2-in. asphaltic concrete per working day of 8 hours. This plant was equipped with a compressed air purveyor for the asphaltic cement.

J. F. Hill used two Cummer railroad plants, each having a rated capacity of 2,000 sq. yd. These plants are mounted on railroad trucks and so constructed that they can be dismantled and made to travel on their own wheels when in transit. They are provided with horizontal revolving drums mounted over a fire box and surrounded with a fire-proof arch through which the mineral aggregate is fed. These plants weigh about 90 tons each and they have their melting kettles, mixing apparatus, boilers, engines and shafts so arranged as to enable one to readily prepare them for transit or for operation after transit. This company carried a fully equipped laboratory and employed experienced chemists at the plant to supervise tests and analyze its mixes and pavements.

The Standard Bitulithic Company used six portable asphalt plants of the Warren type in carrying out its portion of the work. One of the main favorable features of these plants is the fact that they can be put in operation in new locations in a few hours; although simple in their construction, they are so arranged that there is no guesswork as to the proportions of the ingredients, but every step and every portion is under direct control of the operator.

There were fourteen plants engaged on this work during the season, and the main features of the others were similar to those above outlined, or a combination of the same. There was one plant used by the Newton Paving Company, known as the Equitable asphalt plant. This plant differed from all the rest in that the mineral aggregate was put directly into the mixing drum and heated by a hot air blower and then the asphaltic cement was supplied by an air compressor directly from a measuring tank, the stone dust added and the heating and mixing continued until the proper temperature was reached. This plant weighed 36 tons and can be moved readily. It worked very satisfactorily and had an average capacity of 1,000 sq. yd. of 2-in. asphaltic concrete in an 8-hour run; in some instances this amount was exceeded by several hundred yards.

The Borough Asphalt Company mixed its material in a permanent plant located on Newtown Creek, Brooklyn; the capacity is 4,000 sq. yd. of 2-in. material in a run of 8 hours. This plant is probably as complete and well arranged as there is to be found, it being practically dustless when in full operation, and after the first elevation of the material the whole operation is by gravity. All material is under cover and kept from the weather from the time it is unloaded from the scows until it is sent out as a finished product.

The Uvalde Asphalt Company carried out its work from a permanent plant of the usual type located on Newtown Creek in Brooklyn. This plant was located from 6 to 12 miles distant from the site of the work; the material was brought in trolley freight cars to a switch near the work, from which it was then trucked to the street, and in some instances where a trolley track was on the street the material was shoveled directly from the cars into the place to be paved. This plant has a capacity of 4,000 sq. yd. of 2-in. material in an 8-hour working day, and their highest run for a single day of 8 hours was 3,500 sq. yd.

THE PURCHASE OF LIME FOR WATER PURIFICATION.*

By W. F. Monfort.

Lime for water treatment is valuable in proportion to its percentage of water-soluable calcium oxide; but its value is diminished disproportionately by the presence of inert materials natural to the stone—magnesia, alumina, silica—and unburnt stone, although for other purposes these materials may be nearly harmless if not positively beneficial. Hydrated lime has been used by numerous railroad and commercial softening plants and in some smaller cities, but its relatively high cost, the difficulty of feeding it in a large way, and the abundance of dust liberated in handling it have limited its application. In most of the larger plants quicklime is used. The present discussion relates to the vagaries of specifications for the purchase of this latter material.

A contract based solely upon the percentage of lime in deliveries is unjust to the purchaser, in that he pays at contract rate for calcium oxide, however much stone and other impurities are contained. The vendor sells whatever he happens to have; the purchaser receives what he must, without recourse for expense of unloading, crushing, storing, and using a considerable proportion of inert material, which clogs slaking tanks, involves waste of power in stirring, and necessitates more frequent cleaning of tanks. That this expense is not inconsiderable is evident from the following illustration. Between cleanings 253 tons of lime averaging 90 per cent. were slaked at times last year at St. Louis when half the lime used was low in inert matter, against an average of 171 to 175 tons of 83 per cent. lime during the remainder of the year. The accumulation of pieces of core and rubbish from 105 tons of lime caused stoppage of a 10-h.p. motor. The cost of cleaning a tank and starting a new one is approximately 5c. per ton greater with an 83 per cent. lime than with a 90 per cent., not counting the waste of power in stirring. It is obvious that some system of penalizing for impurities should be enforced.

The impossibility of procuring a commercial lime containing 100 per cent. water-soluble calcium oxide influences most purchasers to write specifications upon the basis of a lower guarantee content. In some cases this has resulted in confusion in adjustment of purchase price for better and poorer limes, with purely nominal and misleading bonus and penalty clauses.

If the vendor is to receive full payment for pure lime delivered, with neither bonus nor penalty, the increment is, of course, found by the general formula: 100 guaranteed per cent. = per cent. of contract price to be added or subtracted for each 1 per cent. variation from the guarantee. (See Table I.).

Table I.—Increment for Various Guaranteed Percentages of Lime.

(Without bonus or penalty).

Guarantee.	Increment.	
50%	2.00	of contract price
60	1.666	
70	1.428	
80	1.25	
85	1.176	
90	1.111	
95	1.052	
100	1.00	

Considering a contract based upon a guarantee of 90 per cent. CaO, any bonus or penalty paid or exacted must be by an increment greater than 1.11 per cent. of the contract price; so that, for example, a nominal bonus and penalty of plus or minus 1.5 per cent. of contract price is equivalent to an actual penalty or bonus of 1.5 less 1.11, or 0.39 per cent. of the contract price for each 1 per cent. variation from 90. A nominal bonus of ½ per cent. would be an actual penalty on any basis of percentage guarantee; a nominal penalty of 1 per cent. of contract for each 1 per cent. deviation in percentage of lime delivered below that guaranteed would be an actual bonus on any basis of guarantee other than 100 per cent. CaO.

In considering the fairness of specifications for lime it is expedient to calculate the purchase price per ton as delivered, and the cost per ton of pure lime to the user, as representing the working of the contract from the viewpoint of vendor and purchaser, respectively. By way of illustration, Table II. gives an analysis of some contracts proposed or operative in connection with waterworks plants.

Table II.—Data on Various Lime Contracts.

		A	B	C	E	F
Contract price		$4.23	$4.23	$4.70	$4.23	$3.925

Contract A is unjust to the seller, in that the contract price obtains for any lime delivered which falls within the limits of 90 to 95 per cent. The framers of these specifications intended to be kind in this clause; but the guarantee is actually raised to 95 per cent. for good lime, and lowered to 90 per cent for bad, with no discrimination in what is really the highest range of commercial limes.

The increment of 0.5 per cent. above 95 per cent. is a bonus only in name, as has been shown; the vendor receives

---

* A paper presented to the American Public Health Association, Washington, D.C., and to the Central States Water Works Association, Detroit, Mich., September, 1912.

a trifle more for a 96 per cent. than for a 95 per cent. lime; but the increment is 0.61 per cent. less than the normal increment for a 90 per cent basis (1.111 per cent.), and therefore an actual penalty is placed upon deliveries better than the guarantee. The deduction of 1 per cent. instead of 1.11 for each 1 per cent. below the guarantee leaves an actual bonus of 0.11 per cent. operative. Stated in another way, the actual penalty is put upon the delivery of good lime in that, instead of receiving 111.11 per cent. of the contract price for 100 per cent. lime, as under a contract on a percentage basis, the seller is paid under a supposed bonus clause only 102.5 per cent. of the contract price, while the purchase price on deliveries of 90 per cent. or less is always 10 per cent. of contract price above the per cent. CaO delivered.

From the standpoint of the user, the cost of pure lime is $4.70 in a 90 per cent. delivery; $4.427 in 100 per cent. delivery; $8.46 in a 10 per cent. delivery; $44.63 in a 1 per cent. delivery; whereas unburnt stone at a purchase price of 43c. per ton would afford a ton of pure lime at an infinite cost.

The vendor receives no bonus and has no incentive to furnish good lime; but, since this contract imposes no penalty for poor lime, he has every reason to send the maximum proportion of unburnt stone which will be accepted. The purchaser pays more for poor lime than for good, and suffers further losses entailed by unloading, crushing, using and removing from his tanks this obstructing material. The facts are manifest in the accompanying table and diagrams.

Contracts B and C, though differently worded, yield the same figures for cost of pure lime and for purchase price without bonus and penalty, and give normals for establishing the value of increments in other specifications.

Contract E gives a bonus and exacts a penalty of 0.39 per cent. of the contract price for each 1 per cent. deviation from the guarantee. The vendor, therefore, receives some compensation for care and labor in preparing a well burnt lime; the purchaser is safeguarded to some extent against loss in refuse material. It is probable that a larger increment would result in greater economy to the purchaser, by securing a lime of higher calcium-oxide content and reducing the power cost.

Contract F is now operative at St. Louis, in lieu of Contract A, which was in effect last year. The contract price ($3.925 per ton for 85 per cent. lime) is the average of two lettings to the same contractor. The increment 1.5 per cent. leaves a net bonus and penalty of 0.324 per cent. of contract price, which is again too small, if the advantage of good lime to the department is considered. In the Table III. comparison is made of cost of calcium oxide and of purchase price for contracts A, B and F throughout the range of percentages in deliveries for June-August, 1912.

Table III.—Comparison of Workings of Lime Contracts—1912 Deliveries.

		Per Cent. Delivered.				
Cost CaO		90	85	80	75	70
Contract	A	$4.70	$4.727	$4.750	$4.704	$4.83
	B	4.70	4.70	4.70	4.70	4.70
	F	4.683	4.618	4.526	4.449	4.345
Purchase price						
	A	$4.23*	$4.018	$3.81	$3.50	$3.38
	B	4.23*	3.99	3.76	3.52	3.29
	F	4.22	3.925*	3.62	3.34	3.04

* Contract price.

The average of available lime for eight summer weeks was 85 per cent. on 1,050 gross tons delivered, or 1,572 tons of pure calcium oxide therein contained. Cost per ton of pure lime and purchase price fall below last year's figures by about 10c. per ton for this particular percentage.

In two cities a form of contract is used which gives a bonus and penalty of so many cents per ton for each 1 per cent. departure from the guarantee. Whether this results in payment for lime on a percentage basis; in a bonus for good and a penalty for worse lime, or in a bonus for bad lime and a penalty for better, depends upon the contract price, since the value of the increment with respect to the contract price is a variable quantity. One current contract gives a bonus of 7c. per ton for each 1 per cent. above, and deducts the same amount for variations below the guarantee (88 per cent.). Older specifications gave a bonus and penalty similarly of 14c. per ton on the same guaranteed percentage. Analyses of these specifications on the lines of the foregoing discussion give the results shown in Table IV. (The normal increment for an 88 per cent. lime is 1.13636 per cent. of contract price).

Table IV.—Comparison of Increments, Bonus and Penalty of Lime Purchases.

(Contract Price Assumed at Various Values; Percentage Guarantee, 88 per cent.)

	Nominal Bonus—14c. per ton.		7c. per ton.	
Contract price.	Increment.	Bonus and penalty, actual.	Increment.	Bonus and penalty, actual.
$12.32	1.13636%	0.0 %		
11.00	1.153	0.01636		
10.00	1.168	0.03164	1.084%	0.05236
9.00	1.1866	0.05024	1.09	0.04636
8.00	1.21	0.07364	1.105	0.03136
7.00	1.24	0.10364	1.12	0.01636
6.20	......	....	1.13548	0.000878
6.00	1.28	0.14364	1.14	0.00364
5.00	1.336	0.1996	1.168	0.03164
4.00	1.42	0.2836	1.2	0.07364

Under the first specifications (14c. bonus and penalty) the increment is too small between $6 and $7 per ton, the probable range of prices in that district, with extinction of bonus and penalty at $12.32. Under the second specifications, extinction of bonus and penalty occurs at about $6.20 per ton, leaving above that price a penalty on better deliveries, and a bonus for poorer deliveries than are called for by contract. The amount of bonus is too small to be an incentive to keep the quality of lime delivered up to a desirable standard. In such case dependence must be placed upon some additional clause in specifications as a basis for rejection of unsuitable material.

The common practice in commercial analysis of returning as available the total calcium oxide soluble in hydrochloric acid renders it advisable to incorporate in the specifications a statement of the method of sampling, sample reduction, and of analysis. The scheme adopted in this laboratory follows: Lump lime in bulk is received in car lots and crushed to ¾ in. or less upon receipt. By means of a small pivoted chute at the outlet of the crusher small portions at 15-min. intervals are collected during the unloading of the car making a total sample of about 50 lb. per car. This is passed through a second crusher in order that no pieces exceed ½ in. in greatest dimension. A sample reducing machine described in Engineering News for November 23, 1911, is used to reduce the 50-lb. sample to about 2 lb., after which the entire small sample is pulverized to about 60 mesh in a Sturtevant pulverizer.

In the laboratory a Buskett mechanical riffle reduces the 2-lb. sample to about 14 grams. Approximately 7 grams (8 c.c.) of powdered sample is accurately weighed in a weighing tube, and emptied directly into a 1-liter volumetric flask containing 70 grams cane sugar dissolved in about 800 c.c. cold carbon dioxide free distilled water. Brisk rotation of the flask before introducing the weighed sample prevents caking. Flasks are shaken on a Camp machine 20 min., and allowed to stand over night. The solution is shaken, made up to the mark, mixed thoroughly and 200 c.c. are diluted to a liter, 100 c.c. of this dilution is titrated with tenth normal hydrochloric acid, using phonolptalein. The method is a modification of one commonly used in sugar-house practice (Croghan, C. A., 1908, p. 768).

Delivery of limes containing appreciable quantities of magnesia may be guarded against by a clause in specifications, and occasional analyses made. Limes of the St. Louis district commonly contain less than 1 per cent. magnesia.

Shippers are prone to consider deterioration in transit as working a hardship to them, although the lowered percentage of calcium oxide through absorption of moisture prior to weighing on receipt is balanced by increase in weight of car contents. The protection of the bulk of the car load by the layer of finely divided (air-slaked) lime has been long known. Further, our experience of the summer of 1912 with cars of well-burned lime covered with paper during transit indicates that serious deterioration may be avoided. Two cars shipped and received on the same dates showed the advantage of "overburning" in the meaning of the lime trade. One (ordinary run of kiln, containing some core, and covered with paper), was badly air-slaked, analyzing 76.7 per cent. calcium oxide soluble in sugar solution. The other (well burned—slightly overburned in the opinion of the kiln operator) covered with paper in transit, ran 90.8 per cent. calcium oxide. Fourteen cars of overburned lime in the summer months averaged 88 per cent. The degree of overburning was below that which would make trouble in drawing the kiln; sufficient, however, to greatly reduce the amount of core. The product slaked well. It is better described as well burned than as overburned lime.

Nevertheless, in our latest specifications a clause appears making an allowance from April to October of 2c. per ton for each 24-hour delay in unloading after a lapse of 48 hours from receipt on our tracks. The concession is larger than is equitable; it is, however, rarely operative.

The substance of this paper was put into the hands of all bidders on our current contracts. It was given wider circulation in the hope of directing attention of both writers of specifications and bidders to some essential facts which have been overlooked in purchasing lime for water treatment.

Summary.—Specifications for purchase of lime should be based upon a single percentage guarantee.

Bonus and penalty clauses introduced to guard against loss incident to impurities should be in terms of percentage of contract price.

The increment should be sufficiently large to provide an actual bonus and penalty for variations in quality of lime delivered, and should be based upon the source and quality of lime available.

Instances are cited illustrating the injustice of specifications drawn without analysis of their workings.

Well burned lime ("overburned" of the trade) suffers slight deterioration in transit, especially if covered with paper.

Methods of sampling and of analysis should be described in specifications.

A GRAVEL WASHING PLANT.

The western coast of Canada is the scene of great building activity, which is the result, not of a boom, but of a healthy, though rapid, growth, and although this country is rich in its forests and lumber is plentiful, it is a noteworthy fact that quantities of brick and concrete are being used and the building is being done for the future. On account of the large amount of concrete construction, there is a great demand for sand and gravel and many gravel washing plants have been erected in this territory during the past year. It is also interesting to note that the usual source of sand and gravel in this territory is the river beds, and many of the plants of the western coast have been located on rivers and supplied by barges bringing in dredge excavations.

The plant of the Higgins-Fisher Company is located in Elburne, B.C., a small suburb of Vancouver. This plant is unique in serving a double purpose, enabling one business organization and one plant to serve for two businesses, which have alternate seasons of activity. During the building season the plant receives gravel from barges on the Fraser River, which it screens and crushes and stores in bunkers for supplying the market with concrete aggregate. In winter, coal is received in the same way and is screened and graded in the various bunkers and likewise drawn off to wagons for city delivery. In this way, the one plant serves the purpose of a coal pocket and a gravel screening plant with only an investment equal to that required for either purpose.

When rock or sand and gravel is unloaded from the barges, which is done by means of a grab bucket, it is dumped onto a grizzley, covering the main hopper. This grizzley is set at an angle of 60 degrees, inclined toward a No. 2 Gates gyratory crusher, and all material over 2½ inches in diameter, is rejected to this crusher. The material from the crusher is passed onto a 14-inch Stephens-Adamson belt conveyer, 93 feet centres, leading on an incline to a point above the crushed rock bins. Discharge to the bins is made through a revolving screen which sizes the material and distributes to two compartments.

The gravel, passing through the 2½-inch grating above the first hopper, passes down onto the main conveyer. This conveyer is 24 inches wide and 207 feet between centres; it rises on an incline to a point above the main bunkers and then breaks over a snub pulley and runs horizontally to the farther side of the building. This horizontal run of the conveyer is equipped with an automatic tripper which may discharge to any one of the bunkers, or into a revolving screen, which washes the gravel and separates it into three sizes, namely, 2¾, 1¼ and ¼-inch.

When coal is handled in the winter months, the grizzley is removed from the hopper and the small conveyer and crusher are disconnected by means of steel plate friction clutches, which control the drivers. Coal is then delivered to the main conveyer and distributed over the tripper, directly to the bunkers or through the screen. Coal may then be drawn off through the gates in the bottom of the bunkers. The capacity of the main bunker is approximately 1,000 yards and the small ones hold 150 yards. The drive for the plant is from an electric motor, located at the head end of the main conveyer, and the short conveyer and screens are driven through rope drives from this conveyer countershaft. The crusher is driven from the extended countershaft of the tail pulley of the main conveyer.

Another feature of this plant, and one unusual in most gravel plants, is a car puller, which is used for spotting the cars on the track beside the bins. This car puller makes it a very simple matter for one man to handle a small string of

cars without the use of a locomotive and in considerably less time than is required when using hand car-movers. This car puller is driven from the motor at the head of the main conveyer and the operator uses it simply by winding the rope about the capstan and keeping the rope taut. This produces sufficient friction between the rope and the capstan to move five loaded cars.

This plant was completely designed and equipped by the Stephens-Adamson Company. Both conveyers operate on unit ball bearing carriers, and provision is thus made for a later increase in capacity as well as cutting down the power requirements.

WOOD BLOCK PAVEMENT LAID BY CITY LABOR. *

By Ellis R. Dutton.†

The city of Minneapolis has at the present time over 1,000,000 sq. yd. of creosoted wood paving, laid by day labor. In 1901, the city officials began as investigation of paving materials. Sheet asphalt, laid by contract under a guarantee, was not kept in repair by the company; brick paving was noisy and sandstone blocks wore badly. In 1902, the city council ordered one of the streets to be paved with creosoted wood blocks similar to those used on Michigan Boulevard in Chicago. The blocks were 4-in. southern yellow pine, treated with 12 lb. of Kreodone oil. There were laid 13,500 sq. yd. at a cost of $2.79 per square yard, the city doing all the work by day labor and purchasing the blocks from the Republic Creosoting Company at $1.95 per square yard f.o.b. Minneapolis. These blocks were laid at an angle of 62 deg. with the curb upon a 6-in. natural cement concrete foundation over which was spread a 1-in. cushion of sand. There were no transverse expansion joints but a 1-in. longitudinal joint was made on each side of the street parallel with the curb. These joints as well as the joints between the blocks were filled with paving pitch, and the street was finished with a ¼-in. coating of sand to absorb the excess pitch on top of the blocks. It was considered better practice to lay them at an angle with the curb, instead of at right angles, both on account of the travel and also the expansion; the correctness of this assumption has been proved by experience. The wear up to the present has been only ⅛ in.

Norway and Yellow Pine.—Since Minneapolis is situated in a pine country the use of Norway pine for paving blocks was suggested. Accordingly, arrangements were made for the erection of a treating plant in Minneapolis, if the city would use 30,000 sq. yd. of creosoted Norway pine blocks. The price of this class of blocks was $1.64 per square yard f.o.b. Minneapolis, using 12 lb. of Kreodone oil per cubic foot. In the paving of Third Avenue South in 1903 there were left over from 1902 about 300 sq. yd. of the yellow pine blocks which were used in this street, and the remainder was Norway pine. Samples of these two classes of wood, which had received exactly the same travel and wear, were taken from the street in 1911. The yellow pine blocks showed a wear of ⅛ in. and the Norway pine blocks twice as much. This was an actual comparative test of the two kinds of wood on the same street and under the same conditions.

In 1904 the price for blocks was $1.73 per square yard f.o.b. Minneapolis, but there were proposals as low as $1.51 per square yard, using common commercial creosote oil. The engineers and the paving committee considered the highest blocks treated with the best grade of oil to be the better and cheaper. It was believed that the oil that contained the larger per cent. of residue after distillation to 315 deg. C. was the better. The cheaper oil showed 43 per cent of residue, and the best showed 70 per cent. of residue, and this was the oil used. The wisdom of the purchase has developed by the experience. One piece of work that was done in another city using the cheaper oil never was satisfactory, and has been replaced some time ago with a better grade of paving blocks

Specifications for Oil.—The specifications of 1905 required an oil of a gravity of 1.09 at 20 deg. C. and specified the fractional distillation percentages. These were the first specifications of the kind and they have been followed throughout the country ever since. There is no class of paving that requires rigid inspection more than the creosoted blocks, and if it is possible to obtain a competent person to do the inspecting it is money well spent.

The required amount of oil per cubic foot was raised to 16 lb. this year, as it was considered better to fill the wood more thoroughly and make the blocks more waterproof. This amount has not been changed since, though other cities have put in 20 lb. or more, which I think has caused other trouble. The price of the blocks was $1.49 per square yard f.o.b. Minneapolis for 4-in. Norway pine.

We continued the use of Norway pine tamarac and hemlock until 1911, when we returned to yellow pine blocks which seemed to give the best results, especially on heavy traveled streets. We also used a 3½-in. block on the lighter traffic streets. We have had no trouble with our creosoted block pavements though on one particularly heavy traveled street the Norway pine blocks have worn about 2 in. and will soon have to be relaid.

Cost of Wood Block Pavement.—On January 1, 1912, we had a total of 968,000 square yards of creosoted wood block paving, put in at a cost of $2,466,000, or an average cost of $2.52 per square yard. The prices have varied, as the prices of material varied, from $2.29 in 1908 to $2.82 per square yard in 1907. The price of crushed limestone used in the concrete base averages about $1.75 per cubic yard delivered on the street. The sand costs about 75 cents per cubic yard, and Portland cement has cost from $0.865 to $1.80 per barrel delivered f.o.b. Minneapolis, depending on the year. This cost of paving, as given above, includes the grading for the foundation, the laying of the concrete base, the paving blocks, pitch and all the labor connected with making a complete paving. I have not heard of a city that gets as much for the money as we do. The city of Minneapolis does all of its public work by day labor and has done so for the past 12 years, with the exception of asphalt paving, which it could not do as it had no asphalt plant. The wages paid common labor in paving work has increased from $1.75 per day of 10 hours to $2.40 per day of eight hours in 1912. The skilled labor and teams have increased almost as much in proportion.

To show the preference from the different classes of paving from 1902 to 1912, the following table is given:

Types of Pavement in Minneapolis.

Kind of Pavement.	Sq. Yd. Jan 1, 1912.	Sq. Yd. Jan. 1, 1902.	Increase.
Sheet asphalt	164,441	206,471	*42,030
Brick	390,869	171,144	219,725
Creosote blocks	967,616	....	967,616
Granite blocks	403,915	156,994	246,921
Sandstone blocks ...	347,939	61,661	286,278
Macadam	335,159	129,305	205,854

* Decrease.

CONTENTS OF THIS ISSUE.

ENGINEERING OUTLOOK FOR 1913.

Last year was a period of extensive development throughout Canada. A great deal of construction work of a private nature and for the municipalities and federal and provincial governments was completed. Probably the total cost of the work done totalled more than any previous year in the history of the country.

The indications for 1913 are exceedingly bright, and it is very likely that the total amount of construction work of a public and private nature will far surpass last year; particularly in the West, the towns and cities are increasing in population at so fast a rate that during 1913 it will be very difficult to keep pace with the demand for pavements, sidewalks, water supply, sewerage systems and transportation in general.

A digest of the projected work under the heading of "Engineering Outlook for 1913" will be found on another page of this issue. Its perusal will give some idea of what a few of the municipalities intend doing. These figures are all based on the present financial situation. If the market for municipal debentures improves, however, and it is altogether likely that it will, the amount shown under the different headings will be greatly increased.

It is expected that the public works estimates will total nearly $40,000,000, which will make provision for the works now under contract and for the new ones in view. Last year's total was a little over $30,000,000. It is altogether probable that a vote will be included for the Georgian Bay Canal; probably about $3,000,000. There will be also an additional appropriation for the Welland Canal construction. The Government have signified their intention of co-operating with the Toronto Harbor Commission improvement, which was outlined in these columns some weeks ago, to the extent of $6,000,000. Only a part of this, however, will be voted this session.

Toronto will also secure appropriations for the proposed Federal Square of a half million dollars, and also for progress work on the Toronto barracks. A million and a half will be given to Ottawa for new departmental buildings, and a large amount of money will be spent on the Montreal harbor improvements.

The big appropriations will be for a continuance of extensive harbor works at Victoria, B.C., Toronto, Quebec and St. John, and for the new Intercolonial Railway terminals at Halifax. Tenders have just been called for the two million dollars improvements at the St. Charles River, Quebec, involving the construction of a dam and two locks. Another work for which proposals are being asked is that of improving the river in Pictou to make it navigable. The improvements will greatly add to shipping facilities for the Nova Scotia Steel and the industries. Besides the above, the estimates will make provision for many public buildings, such as post-offices and custom houses at the smaller centres throughout the country.

In connection with the announcement that the Winnipeg-Cochrane section of the Transcontinental Railway is to be opened for grain traffic next week, the total expenditure to the end of the fiscal year was $116,000,000, of which $21,000,000 was spent in the year 1911-12. The total for completion of the work will be around $140,000,000.

REINFORCED CONCRETE AND FORMULÆ.

In view of the diverse opinions from time to time expressed regarding the strength and stability of reinforced concrete structures it is desirable that engineers and architects should determine at what point there is divergence from the common ground of agreement, and in what manner experience with such structures, and the advance of theory respecting design, can be made to dispel the present misunderstandings. The London "Times" states that so long as there is controversy between experts there must necessarily be doubt in the minds of the public, and this attitude will properly be reflected in the restraining laws and ordinances of boards and councils. When the various commercial interests concerned are considered and weighed it becomes obvious that the task of collecting positive evidence must be attended task of collecting positive evidence must be attended with difficulty. Nevertheless, a great amount of work is being done to improve knowledge of the preparation and behaviour of concrete, and contributions to the theory of reinforcement are numerous. Why, then, should the disputings be so prolonged and at times so acrimonious? The answer surely is that it is a war arising largely from terms requiring definition and centring upon a substance which itself is indefinite. Too often equations relating ta perfectly elastic, homogeneous isotropic solids are made to do service for aeolotropic portions of matter, but when such equations are requisitioned for the purpose of solving problems relating to the stresses and strains in sandwiches of steel and concrete, the result is necessarily disquieting. What, for example, is the meaning of the modulus of elasticity in such circumstances? Even in comparatively homogeneous solids this modulus has only a courtesy title to be a constant—it is far more likely to be a logarithmic function of the displacement—and its use as a constant in formulæ relating to reinforced concrete should be either amended or discountenanced. The line of agreement must follow closely the line of direct observation and practical tests on standard sections and frames, followed by makers' guarantees, but considerable assistance would be derived from a friendly conference upon nomenclature and formulæ.

ROADS IN SASKATCHEWAN.

The report of the Highway Commissioners for the current year up to October 31 has been brought into the Saskatchewan Legislature recently. By order-in-council of April 25, 1912, the sum of $1,500,000 was appropriated for expenditures in the construction and improvement of highways, and an additional sum of $100,000 for steel bridges on concrete foundations. The sums were divided by the Commissioners into two amounts, $1,300,000 for highways, and $300,000 for bridges. In the report of expenditures, $663,233.17 is shown, as the total expended on road improvement direct; $56,723.70 expended by municipalities, and $47,923.79 expended on roads under regulations. That is jointly with municipalities. When miscellaneous expenses are added, the total sum expended on road account by the commissioners and municipalities during the period covered by the report is $9;8,070.19.

Provision was made, the commissioners state, for undertaking permanent bridge work to the extent of $300,000. Contracts are under way or entered into that will absorb the whole of the $300,000, but up to October 31 the expenditure did not amount to $100,000.

ENGINEERING OUTLOOK FOR 1913.

The coming year will probably surpass all previous ones in the total amount of municipal construction work to be done. The present plans of a number of the towns and cities throughout Canada, as outlined in the following, will give some idea of the general trend of engineering work throughout the Dominion. The figures as given are in all cases on the conservative side. If the present financial situation improves and the municipalities are able to secure a ready sale for their debentures, the amount of work will be very greatly increased. The country is developing so fast, especially in the West, that the towns and cities will find it exceedingly difficult to provide the necessary accommodation in the way of pavements, sidewalks, water supply, sewerage system and transportation.

Sydney, N.S.—There is no large work in prospect in this city. There will be the usual sewer and water extensions, street and sidewalk work. Estimates are being prepared for a large extension to the waterworks system, but the work will hardly be reached in 1913. City engineer, D. M. Campbell.

Halifax, N.S.—The city expect to construct a 3,000,000-gal. concrete reservoir for the high service water supply system, at an estimated cost of $40,000. Extensive changes to the water distribution system, estimated cost $60,000. The construction of an intercepting sewer along the shore of the northwest arm of the harbor, approximate cost, $100,000. Concrete sidewalk construction, $50,000. Sewer extension, $50,000. City has under construction a garbage incinerator to cost $46,000. The Acadia Sugar Refining Company are constructing a sugar refinery at a cost of about $500,000. The railway department will construct during the next year a terminal pier, total cost, $1,000,000. Contract for this work was made by the Laurier Government. The Dominion Government are making surveys and designs for a new terminal on the waterfront. Estimated cost, $15,000,000, of which the average expenditure will be $1,000,000 a year. The railway department has also under construction a line of railway from Halifax to Musquodoboit. City engineer, F. W. W. Doane.

Public Works Department, Halifax, N.S.—The Department of Public Works, of Canada, district engineer's office, Halifax, which comprises the counties of Halifax, Lunenburk, Hants and Colchester. The annual appropriation for dredging harbor improvements, breakwater, public wharves, etc., will be about $300,000, of which $100,000 is for dredging and the balance for construction. It is expected that a number of large works will be taken up this session and that the appropriations for this year will be larger than usual. District engineer, H. A. Russell.

Fredericton, N.B.—The city will carry on work to an amount upwards of $10,000 on concrete curbs and gutters, pavements, surface sewers; distribution water mains, and sewerage system extension. Some large contracts are contemplated also. City engineer, John O'Neill, B.Sc.

Toronto, Ont.—During 1912 there has been spent on local improvement work about $1,500,000; on storm overflow sewers, $350,000; trunk sewers, $2,000,000; the filtration plant has cost to date $700,000; and the new 36-inch main from the main pumping station to the reservoir, $120,000. In addition a 24-inch and 20-inch supply main was laid at a cost of $120,000. The mileage of pavements laid was 40 miles; the mileage of sidewalks, 52 miles. 2.7 miles of trunk sewer were completed, and there will be about one-half mile to complete next year. It is expected that work on the Crawford Street bridge, Gerrard Street bridge, Toronto Avenue bridge, and other bridges not including the Bloor Street viaduct, will be proceeded with during 1913. An estimated cost of this work

is about $550,000. The following money by-laws are being submitted to the ratepayers: $200,000 grant to the National Sanitarium Association for the fight against tuberculosis; $6,677,000 for a waterworks system at Scarboro' Bluffs; $1,375,000 for a new filtration plant and conduit; $2,500,000 for the Bloor Street viaduct; $1,000,000 for a modern garbage disposal plant; $954,000 for storm overflow sewers. Commissioner of Works, R. C. Harris.

London, Ont.—This city expects to do a good deal of work during 1913. Among other things, the construction of a complete storm water sewer scheme for the entire city is contemplated at an estimated cost of $985,000; a portion of the permanent breakwater on the west bank of the River Thames will be built at a probable cost of $30,000; a highway bridge over the River Thames will be erected at a cost of $30,000; also, the completion of an incinerator plant, capable of disposing of fifty tons of garbage per day; the laying out of a federal square, and construction of a new city hall at a cost of $250,000; the London and Port Stanley Railway, which is owned by the city, will probably be electrified at a cost of $900,000; approximately two miles each of permanent pavement, sidewalks, curb and gutter, and sanitary sewers will be constructed under the Local Improvement Section of the Municipal Act; a good deal of work will be done on the extension of the London Street Railway and the electric lighting of the recently annexed districts composed of Pottsburg, Knollwood Park, Chelsea Green, and Ealing. City engineer, H. A. Brazier.

Sudbury, Ont.—The building permits for 1912 totalled to nearly $550,000. Next year promises to be even greater than 1912. There are many new buildings to be erected; the Bell Telephone Company have called for tenders for a $40,000 building. The Bank of Ottawa will erect a large block, and a $25,000 fire hall will be built. There is a scarcity of contractors for this work as, although tenders were called for the three above some time ago, no tenders were received.

Steelton, Ont.—A waterworks by-law is to be submitted to the ratepayers in January for $50,000 for the installation of an intake pipe, pumping station, force main, standpipe, etc., and it will probably pass. There will be considerable concrete pavements laid, also concrete sidewalks. Some sewer extension work will be done, as well as extensions to the waterworks distribution system. It is expected that $100,000 will cover the amount to be spent in improvements in 1913. W. B. Redfern, town engineer.

Niagara Falls, Ont.—The city will probably spend $50,000 on permanent pavements; $10,000 on permanent walks; $10,000 on sanitary sewers; $25,000 on waterworks extensions. City engineer, J. C. Gardner, B.A.Sc.

County of Welland.—The county will probably spend $100,000 on macadam roadways. Road superintendent, J. C. Gardner, B.A.Sc.

Belleville, Ont.—The city expect to spend on the sewerage system for West Belleville, $250,000. Permanent roads, $75,000; concrete walks, $20,000; buildings, $400,000. Total, $745,000. City engineer, James G. Lindsay.

Welland, Ont.—There is a good year's work ahead in this town. It is expected that 15,000 sq. yds. of street paving will be laid at a cost of $50,000; about four miles of concrete walk, $13,000; 1.7 miles of sewers, 8-in. to 20-in., $25,000. The disposal plant and trunk sewer system will probably be commenced. The estimated cost of this work is $250,000. One and a half miles of water mains (6-in. to 12-in.) will be laid at an estimated cost of $21,500. It is probable that work on the new water intake will be begun; estimated cost, $50,000. The Niagara, Welland and Lake Erie Railway Company will construct about one and three-quarter miles of street railway on North Main, West Main and East Main Streets. The Niagara, Welland and Dunnville Railway Company will construct new lines on Patterson Avenue, Hellems Avenue and Plymouth Road, about one and a quarter miles. It is expected that work on the Welland Canal will commence in 1913. This will mean that under the present plans vast changes will be made in the present layout of the town. Extensive harbor accommodation will be provided and there will be two new heavy swing bridges installed. Town, engineer, D. T. Black.

Souris, Man.—The town anticipate installing an electric light plant at an estimated cost of $40,000. There will also be extensions of sewer and waterworks to parts of the town which are not already served. The present sewer and waterworks system has just been completed, and covers about eight miles of roads. Town engineer, Percy C. Smith.

Winnipeg Man.—The following is a statement of works under construction in this city, or to be constructed in the immediate future. A waterworks reservoir situated at the waterworks main pumping station, Logan Avenue, to be constructed of concrete, capacity 18,000,000 gallons. Excavation for this work nearly completed. In connection with the waterworks extension a series of fifteen wells are being constructed in a northerly course from the city at intervals of one-half mile, the wells being eighteen inches in diameter and to be bored to a depth of 300 feet. The water is conveyed by a steel pipe line eight and a half miles long, to the city. Estimated cost of the works complete, including erection of small pump houses, pumps, etc., is $1,000,000; operation started last week. In connection with the City of Winnipeg hydro-electric plant at Point du Bois, two new units are to be installed at Point du Bois, and a new transmission line erected from that point to the city. The estimated cost of the units with the transformers being $250,000, and of the transmission lines $750,000. This addition has been made necessary by the very large increase in the sale of power in the city. There will be the usual quantity of new work constructed within the city at an estimated cost of $1,000,000, consisting of sewers, water mains, plank and artificial stone sidewalks, asphalt, asphalt macadam, cedar block and macadam pavements. All city work and requirements are advertised and let by tenders. City engineer, H. N. Ruttan.

Department of Public Works, Manitoba.—The department have under construction two large drainage ditches to the west of Lake Manitoba, comprising some 600,000 acres of land, and another district has just been formed in the municipalities of Springfield and Broken Head, embracing 107,000 acres. A drainage system in the municipality of Dauphin is being formed, which will cover about 250,000 acres. Work will be begun on the ditches in the spring. The department have under construction at the Agricultural College at St. Vital a system of waterworks and sewerage. A very large amount of work will be undertaken by the various municipalities under the "Good Roads" and the "Improvement of Highways" Acts. This will be under the supervision of the highway commissioner, who is one of the officials of the department. The department has also under construction a number of important public buildings, namely, the Agricultural College, costing about $2,000,000; new law courts, costing about $1,000,000; insane asylum at Brandon, $500,000; and expect shortly to call for tenders for parliament buildings, which will probably cost $2,500,000. Deputy Minister, Chas. H. Dancer.

Regina, Sask.—This city will build at least eight miles of street paving and twenty miles of concrete sidewalks during 1913. City engineer, F. McArthur.

Saskatoon, Sask.—The following work is contemplated in this city for 1913. On account of the present financial

outlook, there is considerable uncertainty as to the amount of work which will be undertaken; therefore these figures provide only for absolute necessities. Extensions to the sanitary sewer and waterworks system, $400,000; house connections, $75,000; sidewalks, $75,000; pavements, $100,000; storm sewers, $30,000; extension to intercepting sewer, $40,000; additional sedimentation for water purification plant, $35,000; making a total in all of $755,000. However, if conditions from a financial standpoint have improved by spring some of this work will be doubled or trebled. City engineer, Geo. T. Clark.

Prince Albert, Sask.—In view of the present situation it is difficult to say how much work will be done during 1913. The following, however, gives an approximate idea: Street opening and grading, $50,000; sidewalks, $100,000; water main extension, $75,000; sanitary sewers, $100,000; storm sewers, $20,000; electric light, $60,000; disposal works, $60,000; power plant at LaColle Falls (in 1913), $500,000; new pumping plant, $75,000; steam power house, $50,000; making a total in all of $1,090,000. City engineer, F. A. Creighton.

Lethbridge, Alta.—During the past year the city has expended nearly $1,000,000 for improvements, nearly half of which was in connection with the installing of a street railway system. This coming year the ordinary extensions of present utilities will be made. The probable capital expenditure by the city during 1913 will be about $175,000, made up as follows: Sewer extension, three miles, $20,000; water extension, three miles, $80,000; cement walks, five miles, $20,000; street paving, one-quarter mile, $30,000; parks, $10,000; street railway extension, $15,000. There are other expenditures which do not show on the above statement. These include maintenance of all improvements and the expenditure of a large sum to operate the various utilities owned by the city. These utilities embrace a municipal coal mine, water and electric power plant, and street railway.

Medicine Hat, Alta.—The city expect to spend approximately the following amount on the works here listed: Domestic sewers, $150,000; surface sewers, $50,000; curbing, $30,000; sidewalks, $50,000; street grading, $35,000; paving, $250,000; water extensions, $100,000; gas extensions, $50,000; subways, $200,000; fire alarm system, $25,000; public improvements, $40,000; new parks and developments, $60,000; electric light extensions, $25,000; electric power plant extensions, $50,000; making a total of $1,135,000. In a general way it is anticipated that the expenditure of the city for the year 1913 will be $1,250,000. Medicine Hat owns its own water, electric light and gas plants, which are operated as public utilities. All public works are executed by the city construction department on a day labor basis. City engineer, A. K. Grimmer, M.Sc.

Calgary, Alta.—The city contemplates completing three concrete bridges at a cost of about $900,000. The installation of a sewage disposal plant; a water filtration plant; extension of the gravity system by two miles of 42-in. wood stave pipe; building of an asphalt paving plant at a cost of $50,000. Under local improvements there will be 500,000 sq. ft. of concrete walk; 300,000 sq. yds. paving; 50 miles of waterworks; 50 miles of sewerage, including 2½ miles of 42-inch trunk sewer, and an additional 2,000 ft. to the 6-ft. trunk sewer. City engineer, C. S. Dennis.

Macleod, Alta.—City are constructing a mechanical water filtration plant to cost $55,000. It is intended in 1913 to proceed with a system of sewage disposal at an estimated cost of $55,000. The construction of a new trunk sewer and extension to the sewerage system, approximate cost, $32,000. Plans are already prepared for a municipal town hall, to cost approximately $165,000. General improvements in water extensions, concrete walks, etc. City engineer, G. H. Altham.

Fernie, B.C.—By-laws voted on and approved by the city last year, amounting to $35,000, include street improvements; central school addition, and a concrete warehouse and workshop for the city. Provided the debentures are sold this coming year, the above work will be done. The Provincial Government Works Department is calling for tenders for an armory and drill shed, 80 x 130 ft., brick and concrete, with a steel roof truss. Estimated cost, $40,000. Sanitary sewerage system contemplated, $12,000. City engineer, Wm. Ramsay.

PROGRESS ON DESIGN OF QUEBEC BRIDGE SUPERSTRUCTURE.

Considerable progress has been made in the revised design for the double-track cantilever bridge now being built by the Dominion Government across the St. Lawrence River a few miles above Quebec. The board of engineers and contractors has very carefully revised and verified the contract design and modified it materially in some important features and has worked out the principal connections and details of members to an advanced stage of completion. As noted in the Engineering Record, in order to secure the greatest possible accuracy in the computation of dead load stresses and proportioning of cross sectional areas the stress sheets have been repeatedly revised to correspond with successive approximations of dead loads, so that the final stresses are computed from estimates of weight made from the details approved for the actual shop drawings. The detailing is being executed from the centre of the bridge towards the anchorages, and the suspended span has been completely designed, thus giving the true loads on the cantilever arms for which they can be accurately proportioned and the details of the anchor arms finally determined.

This method has the advantage of insuring such certainty and accuracy that Mr. Joseph Mayer, in charge of the computations for the board of engineers, expects to compute the total weight of the bridge within 1 per cent. of the actual shipping weight It is subject, however, to the disadvantage of completing the design first for that portion of the bridge which will last be erected and conversely finishing last the design for the portion which must first be erected. On this account no material has yet been ordered for any part of the superstructure except steel required in the anchorage piers and for the floor system which is independent of the design of the trusses. It is expected that the design and computations will be finished so that the truss material may soon be ordered in detail and fabrication of it commenced during the coming winter.

Some of the principal features of the contract design were illustrated and described in the Engineering Record of April 22 and May 27, 1911. The principal dimensions of the trusses remain the same, but the outline is slightly modified by the introduction of false members connecting the top chords of the centre span and the cantilever arms. The riveted top chord members in the cantilever and anchor arm trusses have been superseded by double lines of 16-in. eyebars in half-panel lengths. Their pins at sub-panel points pass through the webs of light lattice girders connecting the tops of the vertical posts to carry the dead weight of the eye-bars.

The bottom chord, about 10 ft. wide and 7 ft. deep, has a maximum panel length of 86 ft. Each panel will be composed of two pairs of built channels with a full length longitudinal diaphragm making an H-shape section. Each pair of channels has a field-riveted transverse splice midway between main panel points and the two pairs are field riveted together by three lines of very heavy lattice bars extending from end to end and thus forming a full length longitudinal

splice. Each full panel of the bottom chord is thus fabricated and erected in four separate pieces with a maximum weight of about 100 tons for each piece, or 400 tons for the full panel length of member.

The 30-in. pins at the feet of the main vertical posts and bottom chards will take bearing on a built-up pier member resting on sectional cast steel pedestals. The pier members will weigh about 500 tons each.

The stringers are through plate girders fully equivalent to ordinary viaduct spans and are seated with their bottom flanges supported on the top flanges of the floorbeams. One end of each slide to provide an expansion joint in every panel and thus avoid the possibility of transmitting longitudinal chord stresses through the floor system. Wherever the conditions are such that rigid connections between the floorbeams and the truss members might cause the development of excessive secondary stresses the floorbeams have one and sometimes two pin bearings. They are massive plate girders 10 ft. deep with a maximum weight of about 60 tons each.

A large force of draftsmen is now employed by the contractor in working out the details and making shop drawings, and for their convenience and assistance an accurate model of one of the anchor arms of the main trusses is being built in the contractor's city office, adjacent to the main drafting room. It is to a scale of 1/4 in. to the foot, with all compression members represented by solid rectangular pieces of pine to show relative dimensions without details. The eye-bars are made of thin sheet metal, cut to the required shape and dimensions, and the gusset plates and principal connections are also made of thin sheet metal bored for steel pins of proper dimensions. This model has been found very useful in showing relative positions, complicated connections and necessary clearances.

It is proposed to erect the anchor arms on massive steel falsework, which, together with the erection plan, are now being studied and designed. The erection problem is considered as a new and independent one to be treated as a whole with due recognition of local conditions and requirements rather than as the amplification of ordinary construction methods. Special attention is being given to the centre suspended span which will be erected on falsework and floated to position beneath the ends of the completed cantilever arms and connected through vertically slotted holes to ends of adjustable plate hangers suspended from the cantilever arms. The span will be lifted to position by specially powerful hydraulic jacks. In order that there may be no possibility of a drop on account of any failure of the jacks, the lifting movement of the latter is followed up by a system of power driven wedges, which prevent any slips of the hangers at all stages of the operation.

Extensive new shops with a complete equipment of powerful electrically driven machine tools have just been constructed for the fabrication of the steel work at Lachine, near Montreal, at an estimated cost of nearly $1,000,000, including the cost of the very valuable site. It is anticipated that this expense, together with the purchase of materials, cost of labor, equipment and erection plant, plus the required surety deposited, will aggregate $3,000,000 more than the contractors will have received in payment at the time erection is commenced.

The design and construction is under the direction of a board of engineers, composed of Mr. C. N. Monsarrat, chairman and chief engineer; Mr. C. C. Schneider and Mr. Ralph Modjeski. The contract for the steel superstructure was awarded to the St. Lawrence Bridge Company, of which Mr. Phelps Johnson is president, and Mr. G. H. Duggan, chief engineer. Mr. S. P. Mitchell, Philadelphia, has been retained as consulting engineer for the erection

THE GAS ENGINE AS AN ECONOMICAL POWER PRODUCER.*

By W. C. Mountain.

Gas engines have been very greatly improved in design and construction during the last few years and undoubtedly offer the most economical means of producing power. The heat consumption of large gas engines in practical working is about 10,000 B.t.u. at normal full load and about 9,500 B.t.u. at the maximum overload. The net heat value of blast-furnace gas varies with the duty of the furnace and the character of the fuel used, but in general varies between 90 and 110 B.t.u., or, say, 100 B.t.u. per cu. ft. as an average. Therefore, the consumption of blast-furnace gas per brake horse-power per hour would be approximately 100 cu. ft.

With coke-oven gas the heat consumption is the same. The heat value of coke-oven gas varies considerably, but is generally in the neighborhood of 450 to 500 B.t.u., occasionally less. Taking 450 B.t.u. as the usual figure, the consumption per brake horse-power per hour at normal full load is about 22½ cu. ft.

The exhaust gases from gas engines can also be used for generating steam, and when an engine is developing something like its full load, from 2 to 2¼ lb. of steam per brake horse-power at 60 lb. pressure is regularly generated, and this steam can be utilized for driving auxiliaries, heating and other purposes.

As regards the power available from blast-furnace and coke-oven plants, the following figures are interesting:

The calorific value and volume of gases evolved by a blast furnace depend upon the character of the furnace burden, and to some extent upon the method of driving, but, as an average figure (Northeast Coast practice) the gas evolved per ton of pig iron produced is about 160,000 cu. ft., measured at atmospheric temperature and pressure. Of this gas, about one-third is used by the ovens, about one-eighth by the blowing engines (if driven by gas engines), and about 10 per cent. is lost or used up in miscellaneous ways; thus about 45 per cent. of gas is available as surplus, or approximately 72,000 cu. ft.

Taking an average heat value of 100 B.t.u. per cu. ft., the horse-power developed by large gas engines would amount to about 30 brake horse-power for every ton smelted in 24 hours. If ordinary steam blowing engines were already installed, the available surplus would drop to about 25 brake horse-power per ton of pig iron in 24 hours, and might even
horse-power per ton of pig in 24 hours, and might even

With coke ovens the production of gas naturally varies with the quality of the coal, but an average figure is 10,000 cu. ft. of gas per ton of coal. The surplus gas, when regenerative ovens are employed, amounts to about 5,000 cu. ft. per ton of coal. Where non-regenerative ovens are employed, the surplus is very much less, sometimes amounting to 2,500 cu. ft. In these cases the high temperature of the escaping gases enables a good deal of steam to be evaporated by suitable boilers heated by the waste gases. Roughly speaking, about 1 to 1¼ lb. of steam will be generated for each pound of coal coked, and this steam may be used for driving steam turbines or other classes of engines. It will thus be seen how much power can be obtained by utilizing what was at one time a mere waste product.

---

* Abstract of the presidential address delivered at the annual meeting of the British Association of Mining Electrical Engineers, in Sheffield, England, Sept. 27, 1912.

CLAY PRODUCTS OF CANADA.

The actual production and sale of clay as such in Canada is as yet very small and practically limited to a small quantity of fire clay sold by a few operators. With this exception, all of the clay production in Canada is manufactured by the producer, states Mr. J. McLeish, B.A., chief of the division of mineral resources and statistics in his annual report.

The clay products made in Canada comprise brick of various kinds, including common and pressed, ornamental and fancy building brick, paving brick, firebrick, porous fireproofing brick and blocks, sewer pipe and drain tile, pottery and sanitary wares, the last two products chiefly from imported clays.

The production of clay products has been rapidly increasing, the value of the output having almost doubled in three years. The total value of the production in 1911 was $8,359,933, as compared with a value of $7,629,956 in 1910, showing an increase of $729,977, or over 9.5 per cent.

While the increase in gross output was not as large as that shown in 1910, the industry apparently made very satisfactory progress during the year.

Demand in most districts exceeded supply and higher prices generally were realized. For the year 1911 about 419 active firms reported, as against 438 active firms reporting for 1910. A larger number of men were, however, employed in 1911, an average of 9,131 being engaged, as compared with 8,656 in 1910; while the wages paid were $3,524,058 in 1911, as against $3,308,609 in 1910.

Considered by provinces, Ontario in 1911 had the largest output, being credited with 47 per cent. of the total value. Quebec was second with 16 per cent., Alberta third with 12½ per cent., Manitoba fourth with 10 per cent., followed by British Columbia with 8 per cent.

In 1907, Ontario contributed 54 per cent. of the production of clay products, while the western provinces contributed only 21 per cent., as against over 33 per cent. in 1911.

Of the total value of production in 1911, building and paving brick, including fireproofing, contributed $6,915,792, or nearly 84 per cent.; sewer pipe and tile production were valued at $1,152,528, or about 14 per cent. of the total.

The total value of the production of pottery was reported at $439,264, of which $102,493 is estimated as being attributable to Canadian clays and the balance to imported clays; the value of production of fireclay and firebrick was $89,130. Compared with the previous year, the production of building, paving and fireproofing brick shows an increase of nearly 12 per cent., while the production of sewer pipe and drain tile increased less than one per cent.

The average price of common building brick for the whole of Canada in 1911 was $8.37, as compared with $8.13 in 1910 and $7.81 in 1909. The average price of pressed or front brick for the same years was, respectively, $12.53, $11.89, and $11.01, thus showing the general increase in cost of building brick.

The total value of the imports in 1911 was at least $5,156,544 (certain items probably covering clay products not being included), showing a total approximate consumption of clay products valued at $13,416,537, of which only 62 per cent. was of domestic production.

In 1909 the approximate consumption was valued at $9,172,995, of which about 70 per cent. was of domestic production.

In the case of building brick, the imports while increasing rapidly are still small compared with the home production; it is different, however, with paving brick and firebrick. The imports of paving brick in 1911 were over twice, and the imports of firebrick nearly ten times the Canadian output.

While the production of sewer pipe and drain tile remained nearly stationary, the imports of these products more than doubled in 1911, and amounted in value to about one-third the domestic production.

CONSTRUCTION OF CONCRETE GRAIN ELEVATORS.*

By R. P. Durham.†

There is nothing in connection with the construction of foundations and first story of a concrete grain elevator, and very little in the construction of the cupola, calling for special comment as to method of procedure. Aside from the fact that foundation loads are exceedingly heavy and the item of the complicated construction sometimes necessary in the cupola, the ordinary methods of concrete warehouse construction are in general followed in building such portions of grain elevators. The building of the bin walls has, however, developed a method of construction not used, as far as I am aware, in connection with other buildings. This arises from the great height of bin wall of the same thickness, which early suggested that a short form which could be moved up continuously would be the most economical design.

All moving bin forms have certain characteristics in common, the variations between those used by different contractors, or by the same contractor at different times and on different work, being more in method than in principle. The form consists of horizontal framing pieces to which vertical sheeting is attached. The form may vary in height from 3 ft. to perhaps as much as 5 ft., measuring by the length of the vertical sheeting, but is always a comparatively short form. It must, of course, extend along both sides of each wall, the forms on the two sides of the wall being connected by vertical timber or steel yokes which are usually attached to the horizontal framing of the form. The sheeting is generally of wood dressed on the side in contact with the concrete. Galvanized sheet steel on a wood framework has also been used, and in some cases the wood sheeting itself has been covered with steel, either on the forms for the outside walls or on all the forms. The purpose of covering the wood sheeting or lagging with sheet steel has been to make smoother walls. It has been found that the use of steel is not necessary if the raising of the form is carried on rapidly and continuously and a gang of pointers follows closely after the moving forms. In such cases the wooden sheeting has produced workmanship which is all that can be desired and in some ways is superior to that produced by stationary forms.

The principal difference in methods of building bin walls with moving forms is dependent upon the procedure followed for raising the forms. It is necessary, in order to obtain walls which are smooth and results which are economical, that the forms be raised continuously and that the movement be at a steady rate. The concrete at any particular point must have a reasonable length of time to harden before the bottom edge of the sheeting gets above it. This means that the progress in any one day is limited to a maximum of approximately twice the depth of the form, which insures that there will never be any exposed concrete which is less than 12 hours old. Assuming a 4-ft. form, this means that the movement must not exceed 4 ft. in 12 hours, and it is generally less than that; so that a very slow, but at the same time a very steady, upward movement is desirable. It will probably be asked, Why not build forms with longer sheeting and jack faster? The answers are, first, that it is not desirable to put a much greater load on green concrete; and second, that 6 to 8 ft. of concrete a day on a large building has been found to be the maximum which can be got

* Abstract of paper delivered to National Association of Cement Users, Pittsburg, December 10-13, 1912.

† Vice-President, John S. Metcalf Company, Limited, Montreal.

into the forms, when the placing of reinforcing and other items tending to delay have been considered.

The Canadian Pacific Elevator at Port Arthur, built in 1903, was the first elevator as far as I am aware on which moving bin forms were used. The jacking was done by means of, I think, ordinary locomotive jack screws. Brackets were fastened to the lower horizontal members of the forms and the jacks were set on vertical posts, with the top of the jacks bearing against these brackets. As the forms were raised to the limit of each jack, another section of post was added below the jack and the entire form structure thus gradually raised from bottom to top by increasing the length of the post. The jack posts were probably of varying length so that all jacks would not have to be released simultaneously.

Another method of raising moving forms, and that used by our company at the Missouri Pacific Elevator, Kansas City, and on one or two other contracts, was somewhat similar except that the jack was placed at the bottom of the bin instead of at the top next to the form. Locomotive jack screws were placed below the posts and the entire form structure and scaffolding gradually raised, the new sections of post being put in at the bottom from time to time as the limit of travel of any jack was reached.

After this time, with the increased number of concrete elevators being constructed and the increased number of engineers working on schemes for raising the forms, the method of jacking becomes more diversified. The style of jacks may, however, be divided into two general classes, the screw jack and the pump jack. The former depends on the travel of a nut on some form of threaded rod, either in the jack or in the bin wall; the latter depends on a toggle arrangement operated by a lever with pump handle motion and working on a plain rod. Practically all builders now support the forms, not on a scaffolding between the bottom of the bin and the form, but on steel rods which are embedded in the bin wall. The jack travels upward on these rods, the jack itself generally being attached to the yoke, to the lower end of which the bin forms on either side of the wall are secured.

The question as to whether the pump jack or the screw jack is the better style is one on which experts disagree. Some who have used both kinds are very much in favor of the pump jack; others who have had experience with both kinds stick to the screw jack. We have experimented with the pump style, but have never seen fit to adopt it in actual construction work. We have used two or three different styles of screw jacks and have built about 10,000,000 bu. capacity of storage bins with the jack we are now using. In this case the vertical rod which is embedded in the wall, and on which the jack operates, is threaded the entire length with a double V-thread about 3½ pitch. The jack casting is attached to the yoke and consists of one supporting casting and a revolving casting with apertures for the jack levers. The revolving casting is set over a square nut on the threaded jack rod. As the revolving casting is turned the nut climbs the jack rod and the yoke and forms are raised. This jack enables us to make steady progress, is capable of exerting great power in case of the forms sticking, and is sufficiently fast. On two different sections of the Montreal Harbor Commissioners' elevator, each section being about 150 x 100 ft. in plan, we have run up 86 ft. of bin walls in less than 14 days, or better than 6 ft. per day. This is, of course, working night and day; for if a moving form is stopped after it is once started a joint in the work is sure to show, and generally a small offset or shelf is left at the joint.

One company uses another type of screw jack; in its case the vertical rod in the wall is a plain rod. The jack is, briefly, an extra heavy pipe about 2 ft. long and threaded on the outside. The jack rod runs through this pipe, which is provided with a clutch at the lower end. The travelling nut operates on the pipe and when the limit of travel has been reached the clutch is released, the threaded pipe run to the other end of the travel and the operation repeated. The company has secured good results with this jack. The Macdonald Engineering Company, of Chicago, on the other hand, after trying various styles of jacks, has abandoned screw jacks altogether and uses only a pump jack.

The rate of progress of which I have spoken is possible only with a comparatively quick setting cement such as is used in the United States and Canada.

It is not possible to build a very thin wall with a moving form, the determining factor being the relation between the weight of the concrete in the form and the friction of the concrete against the sides of the form. The area of form exposed to the concrete is the same no matter what the thickness of the wall, while the weight, of course, varies in direct proportion to the thickness. I think it is entirely practicable to build a 6-in. wall with moving forms, but that it is dangerous to go much below this unless very special precautions are taken to prevent lifting of the concrete. We have built concrete elevator legs 2 in. thick with moving forms and got good work, but in that case we lifted the forms with chain blocks and went with comparative slowness.

The speed of the work and the freedom from trouble will also depend somewhat on the aggregate used and, it would seem in some cases, on the cement. Three elevator builders have had trouble with one particular brand of cement in moving forms and decline to use it further. A fourth has used it with success and is not afraid of it. Whether the trouble arises from this particular cement having properties which cause it to stick to the forms more than other cements, or whether it sets before the forms have been moved and thus causes the top of the walls to break away from the portion below it, is a question no one, not even the cement people themselves, has been able to answer satisfactorily.

The question of aggregates seems to be a comparatively unimportant one. We have had good results with crushed stone concrete and with gravel concrete. The crushed stone concrete has, perhaps, less tendency to lift in the forms, but on the other hand, on account of the likelihood of sharp corners of the stones catching in the wood of the sheeting when tamped and thus being displaced as the form is raised, smoother walls are generally obtained with gravel concrete. We have successfully run bin walls with sand and cement alone, though in general we should consider this taking a chance because of the tendency of a concrete mortar to stick to forms.

CONCRETE BRIDGE DESIGN.

In a recent paper on concrete bridge design, Daniel B. Luten, Indianapolis, Ind., states that the ideal highway bridge must include among its qualifications the following: Permanence, eliminating repairs, artistic appearance to harmonize with its surroundings, strength, increasing with time and traffic, safety, meaning not merely security, but slow failure in case of defects; stable on insufficient foundations and under extreme flood conditions, effective waterway providing maximum discharge, efficient and economical in use of materials, employing home labor and materials, providing a roadway continuous over bridge and approaches, easily widened to provide for increasing traffic, easily modified in design to conform to improvement in surroundings, simplicity in design and erection.

SEWAGE TREATMENT STANDARDS.

By R. O. Wynne-Roberts, M. Inst. C.E., F. R. San. I.

The Royal Commission on Sewage Disposal has just issued its eight report, which deals with "standards to be applied to sewage and sewage effluents discharging into rivers and streams."

The commission has had under consideration tests of which three have been more fully investigated, viz.:

1. The quantity of ammoniacal nitrogen present.

2. The quantity of oxygen absorbed from permanganate in four hours.

3. The quantity of dissolved oxygen taken up in five days.

Of these tests the commission consider the last provides the most trustworthy chemical index of the actual state of a stream and should be adopted for purposes of a standard.

It appears that this test has been objected to an the grounds that it is difficult to carry out, and gives discordant results. But, in the opinion of the commission, the objection is not well grounded. A considerable number of chemists at different British sewage works have made numerous tests and with a little practice any well-trained chemist can apply it with ease, and obtain accurate results.

The commission concluded, after many experiments, that if 100,000 cubic centimeters of river water do not normally take up more than 0.4 gram of dissolved oxygen in five days the river will ordinarily be free from signs of pollution. If, on the other hand, a greater absorption of dissolved oxygen takes place, then the river will almost certainly show signs of pollution, except perhaps in very cold weather.

This "limiting figure," in the opinion of the Royal Commission, should be the foundation upon which standards should be based.

As temperature is an important factor, the results of five days' tests will vary during varying temperatures and different seasons. So, the commission carried out the experiments at a constant temperature of 65 deg. Fahr. A stream can be more highly polluted in cold weather without creating a nuisance and, therefore, the above standard temperature has been adopted.

The amount of dissolved oxygen taken up in five days by a mixture of river water and sewage effluent depends (a) on the amount taken up by the sewage, (b) on the amount taken up by the river water, and (c) on the proportion in which the two liquids are combined. A mixture complying with the standard of 0.4 parts dissolved oxygen per 100,000 of water may thus be expressed in equation form as follows:

$$\frac{x + yz}{z + 1} = 0.4$$

x = parts of dissolved oxygen taken up per 100,000 parts of effluent.

y = parts of dissolved oxygen taken up per 100,000 parts of river water above outfall.

z = dilution (proportion of river water to effluent).

Thus, for example, (given in report) if an effluent is discharged into 10 times its volume of water which itself takes up 0.1 parts of dissolved oxygen in five days the formula gives

$$\frac{x + (0.1 \times 10)}{10 + 1} = 0.4$$

$$x + 1 = 4.4$$

$$x = 3.4$$

In other words, the effluent in this case may be permitted to take up 3.4 parts of dissolved oxygen per 100,000 in five days and that figure would be the standard for this particular discharge.

The commission report goes on to state that a standard should be fixed which would be suitable for majority of places. But in Canada this must manifestly be varied, as what will apply in rapid streams will not suit sluggish and small streams. This is a point which the report deals with when it states that provision should be made for fixing one or two higher or lower standards to meet cases in which a different standard could be justified.

After making allowance for the practical difficulties in the way of removing suspended solids in a uniform manner, the commission considers that the dissolved oxygen test should be applied to the effluent as discharged, that is, with its suspended solids, and recommend that the normal figure for dissolved oxygen absorption test should be fixed at 2 parts per 100,000.

An effluent which takes up 2 parts of dissolved oxygen in five days will need some dilution if nuisance is to be avoided. The minimum degree of dilutes required for safety is to be found by means of the formula

$$\frac{2 + (0.2 \times z)}{z + 1} = 0.4$$

$$z = 8$$

The commission recommend that in the case in which a complete system is called for, the effluent should not contain more than three parts of suspended matter per 100,000, and that, including its suspended matters, it should not take up more than two parts of dissolved oxygen per 100,000 in five days at 65 deg. Fahr. (18.3 deg. C.). This standard is given for normal conditions and in special cases should be modified.

Where the dilution is very low it is suggested that the standard should be made more stringent, and if the dilution is very great the standard may be relaxed.

The commission state that their experience leads them to think that as a general rule if the dilution, while not falling below 150 volumes, does not exceed 300, the dissolved oxygen absorption test may be omitted, and the standard for suspended solids fixed at six parts per 100,000.

There are several other points of interest in this report which may be referred to later on.

LATHE FOR TURNING PROJECTILES.

A motor-driven lathe for turning projectiles has recently been developed. This service requires rigidity of equipment and wide speed range; a very high spindle speed is necessary when finishing the point of the projectiles. The lathe, which is of Pond make, is especially designed for individual motor drive, and is not a belt-driven lathe modified for motor drive; the motor is placed on the lathe head, thus saving floor space, and doing away with any chance of injury to employees from coming in contact with the motor or gears; at the same time the motor is protected from harm.

The control handle is to the extreme right of the tool apron, and very convenient for the operator.

The lathe is driven by a Westinghouse 20-h.p. machine tool motor, 400-1,500-r.p.m. Commutating poles insure excellent commutation at all loads within its capacity.

With the liberal speed adjustment of the motor, in combination with the gear-changing device operated by means of the levers at the left end of the tool, the wide adjustments needed in turning up projectiles are made readily available.

LIME-SAND BRICKS.

The manufacture of lime-sand bricks on a commercial scale was commenced in Germany about the year 1894, since which time many improvements have been made in the design and construction of machinery especially adapted for the purpose. That the industry is far beyond the experimental stage is proved by the fact that in Germany numerous plants are in operation, producing, it is estimated, over 1,000,000,000 per annum, Berlin alone consuming 400,000,000 annually. In the United States about 150 plants are in operation and many are being erected, the output for 1910 in the States being estimated at 350,000,000. In other countries the progress has been slow, but plants are now being erected in all parts of the world.

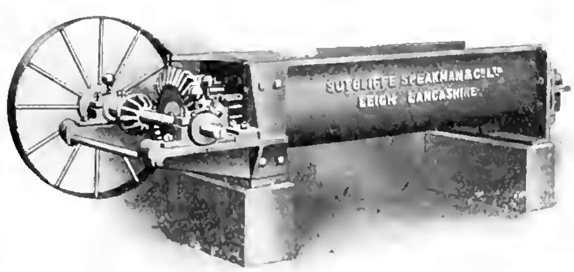

Fig. 1.—Differential Mixer.

Lime and bricks, as their name implies, are made from a mixture of slaked lime and sand. These materials, being suitably prepared and thoroughly mixed, are pressed into brick form by powerful presses, and then hardened by the action of high-pressure steam in suitably closed hardening chambers or vessels for a period ranging from eight to ten hours, the whole period of manufacture from taking the raw materials to completion ready for building not exceeding 24 to 26 hours.

They possess many advantages. Being perfect in shape, and uniform in size, less mortar is required in laying them, and when used for inside walling one coat of plaster is sufficient, the face of the wall being quite true. Their specification and use by the governments of Australia, Germany, Sweden, America and other countries are sufficient to prove that they are found to have all the weather-resisting and other properties of a durable brick. In general, they have the appearance of a natural sandstone, and may be compared to a good even-grained one; in fact, there are many varieties of sandstone from which they cannot be distinguished. They are cheap to manufacture, being made at a less cost than clay bricks, and when reasonable care is taken in making them, every brick is a facing brick. Their natural color depends upon the sand and lime used; generally they are white or gray, but variety in color may be obtained by the use of coloring ingredients.

PRINCIPLES OF MANUFACTURE.

Percentage of Lime Required.—As mentioned before, they are made from a mixture of sand and lime, the proportions varying with the kind of sand and the purity of the lime. A good, clean, silicious sand, consisting of well-graded fine and coarse particles mixed with 5 to 6 per cent. of a good fat lime gives excellent bricks, but in some cases up to as high as 8 or even 10 per cent. lime will be required. If the lime is hydraulic or an impure lime, or is not thoroughly calcined, the higher percentage is required. The average composition may be taken to run as follows:

Sand	85 per cent.
Lime	8 per cent.
Water (in combination)	7 per cent.

Preparation of the Materials.—Before the materials are ready for pressing it is necessary to ensure that the lime is thoroughly slaked, or hydrated and the mixing of the lime and sand intimately effected. If this is not effected the bricks will either crack or swell during the steaming, or be of a very weak and friable nature. When the manufacture of these bricks was first commenced, it was thought to be a simple matter to slake the lime, and that it could be done in the same way that builders prepare their lime. This method was soon proved unsuitable. If insufficient water was added, the lime was not slaked, and if too much water was added, the lime was made too wet, and it was impossible to make a homogeneous mixture. To overcome this difficulty, numerous methods have been adopted and the difficulties overcome as they have arisen by such systems as the nature of the material and the existing conditions on the site may demand. Exhaustive tests have proved that by proper methods lime-sand bricks of good quality may be made under almost any conditions, and that crushing strength and absorption varies with the qualities of the sand and lime used. By finely grinding through a tube mill of the preliminary mixture the results are excellent as the following figures from results of tests made will show:

	Crushing strength in tons per sq. foot.	Absorption.
Ordinary bricks made without fine grinding through tube mill, tested when 3 days old	150 to 400	8 to 12 per cent.
The same, but material treated in tube mill	300 to 600	3 to 7 per cent.

It is well known that lime-sand bricks improve with age, due to the further combination of lime and silica and to the absorption of carbonic acid from the atmosphere converting any uncombined lime into a carbonate.

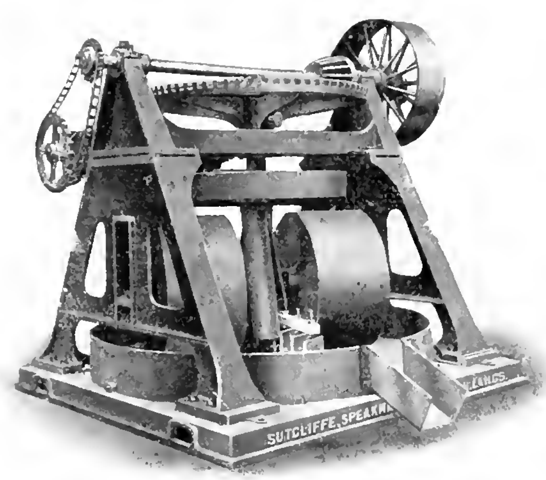

Fig. 2.—Edge Runner Mixing Mill.

Pressing the Bricks.—For pressing the material into bricks, the press must be a strong and powerful one, the bricks requiring a pressure of at least two tons per square inch, or a load of 80 tons on each brick. One hundred tons is preferable and is recommended. The pressure must be applied slowly in order to press out the air, and when the bricks are required for facing purposes they should be pressed equally on top and bottom.

Hardening the Bricks.—After coming from the press, the bricks are stacked closely together upon platform wagons, each wagon holding 650 to 800 bricks. They are then wheeled into hardening chambers or autoclaves. These are steel cylindrical vessels similar to Lancashire boilers without

flues, one or both ends being fitted with a removable door. In these chambers the bricks are subjected to the action of steam at a pressure of 120 lbs. per square inch for a period of 8 to 10 hours. This treatment hardens the bricks and when drawn from the chambers they are ready for use.

Machinery and Plant Used.—For a successful manufacture of these bricks it is necessary that machinery of high-class make, specially designed for the purpose, be employed.

Through the courtesy of Messrs. Sutcliffe Speakman and Co., some particulars of the machinery they make for this industry are herewith given.

For the fine grinding of the lime an improved ball mill is used. These mills are made in sizes depending upon the work to be done.

When the fine grinding of the preliminary mixture is adopted, the use of the tube mill is recommended. This mill consists of a long steel tube, revolving on tyres and rollers. The tube is lined with silica paving, and is charged rather more than half full with hard flint pebbles. The material to be ground is fed in at one end, and passes out automatically at the other end, the grinding being effected by the rolling and tumbling of the pebbles on the material.

The differential mixer is illustrated in Figure 1. Various sizes are made to suit the output required. It is used both for the first mixing of the materials for the silo and for the final mixing prior to the mixture being pressed into bricks. The mixer consists of two shafts carrying knives or blades set at an angle to propel the material through the containing trough. One shaft revolves twice as fast as the other and the two shafts revolve in opposite directions. It forms a very simple and efficient mixing apparatus.

The mixing mill is shown in Figure 2. It consists, as shown, of two rollers revolving in a stationary pan, and so works that the material is not only turned over and mixed by the scrapers, but at the same time the crushing action of

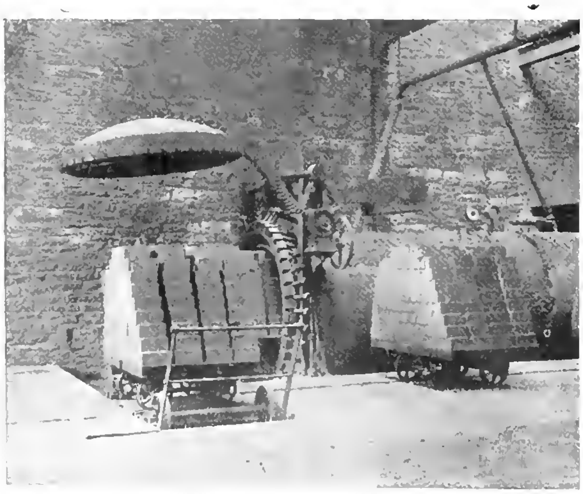

Fig. 3.—Hardening Chamber End, Showing Door Opening Arrangement.

the rollers gives a kneading effect. It gives a mixture in which each particle of sand is painted or covered with a thin coating of lime. It is made in various sizes and with rollers ranging up to five tons in weight each.

In any lime-sand brick plant one of the most important items is the press, as upon this depends more particularly the output, the general quality, and the finish of the bricks.

After an extensive experience in press manufacture, the result of the company's work is the "Emperor" press. This is a rotary table press capable of pressing the bricks equally from top and bottom.

The hardening chambers are specially designed for the required pressure, usually 125 lbs. per square inch, and are constructed in accordance with the requirements of the insurance companies. The most usual diameter is 6 ft., but on occasion they are made up to 6 ft. 6 in. and 7 ft. in diameter. Figure 3 shows the ends of a chamber and the arrangement recommended for opening the door.

When fuel is expensive and freights high, and first cost of plant is required to be reduced as far as practicable, small hardening chambers are supplied 3 ft. in diameter,

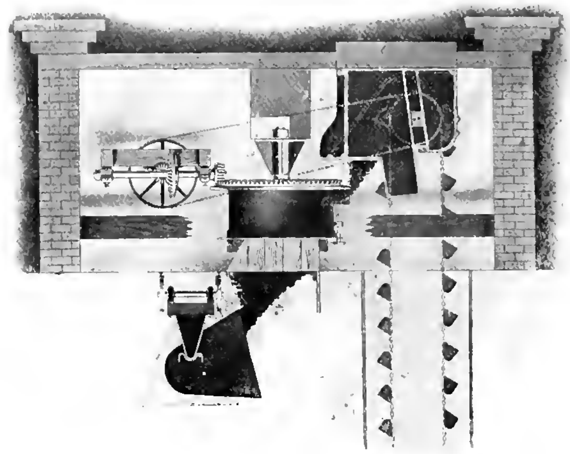

Fig. 4.—Automatic Feeder.

working at 200 lbs. pressure. This admits of steaming being effected in four hours, and if the chambers are so arranged that they can be operated day and night, the saving of steam is considerable, as one chamber can then be arranged always to exhaust into one ready for steaming.

For automatically measuring the feed to elevators and mixers circular automatic feeders, as illustrated in Figure 4, are used. This illustration shows the feeder automatically feeding an elevator. A wagon load of material can be tipped into it at one time, and it can be adjusted to pass the material at the required rate of feed.

This prevents the possibility of choking the elevators, and does away with the necessity of labor feeding the machines or elevators, whilst at the same time it acts the part of a measurer

MOVING A LONG BRICK WALL.

In order to widen the train shed of one of the railroad stations in Antwerp, Belgium, it was found necessary to move a brick wall, about 236 feet in length, a distance of 80 feet. The plan first decided upon consisted of demolishing the wall and rebuilding it of the same material at the new location, but when the contractor undertook to do this he found that the masonry construction was so solid that tearing it down would so damage the old material that it could not be used again. Therefore, he had the wall cut off in one solid piece, and moved on rails to its new location. The complete operation was accomplished by 18 men in 14 days, the actual moving taking but 27 minutes. The plans were so well carried out that not even one crack appeared in the wall.

At Souris, Manitoba, a money by-law to authorize the expenditure of $40,000 for electric lighting was defeated because the majority was one vote less than the required sixty per cent. necessary for it to become law.

MINING IN ALASKA IN 1912.

The annual report on the mineral resources and production in Alaska for 1912 is now in preparation, under the direction of Alfred H. Brooks, of the United States Geological Survey. Some of the important features of this report relating to mining development during the year are abstracted in the following statement. Complete statistics of the mineral production of Alaska cannot be collected within less than four or five months after the close of the year, but meanwhile it appears advisable to give prompt publication to preliminary estimates, which are believed to be not over 5 per cent. in error.

Value of Mineral Output.—It is estimated that the total value of the mineral output of Alaska in 1912 is $21,850,000, compared with $20,650,000 for 1911. The value of the gold output of 1912 is estimated at $16,650,000; that of 1911 was $16,853,256. It is estimated that the Alaska mines produced 28,940,000 pounds of copper in 1912, valued at about $4,630,000. In 1911 the output was 27,267,871 pounds, valued at $3,364,584. The silver production in 1912 is estimated to have a value of $300,000, as compared with $243,923 for 1911. The value of all other mineral products in 1912, including tin, marble, gypsum, coal, petroleum, etc., was about $260,000, compared with $176,942 in 1911. The total value of Alaska's mineral production since 1880, when mining first began, is, in round numbers, $229,000,000, of which $202,000,000 is represented by the value of the gold output. The total output of copper in Alaska since 1901 is about 90,000,000 pounds, valued at about $13,145,000.

Important Features.—The increase in the value of Alaska's mineral output is to be credited to the larger copper output as compared with the previous year. While no new copper properties were put on a productive basis, a large amount of development work was accomplished in several of the copper-bearing districts. The gold-mining industry was marked by important advances in developing lode deposits. Work was continued on a number of large lode-mining enterprises in the Juneau district, and considerable advances were made at Fairbanks and in other districts. In addition to this, promising discoveries of auriferous quartz were made at Port Wells and in the Innoko-Iditarod region, as well as in other parts of the territory.

The output from the placer mines was less than in the previous year. On the other hand, discoveries of rich auriferous gravels were made on Hammond Creek and in the Koyukuk Valley, and workable placers were found in the Ruby district. Extensions of gold-bearing gravels were also found in several of the older districts. The installation of large plants has not yet gone ahead rapidly enough to insure the keeping-up of gold-placer production. It is significant, however, that the output in Seward Peninsula was practically the same as that of 1911. The maintenance of this output in Seward Peninsula is to be credited to the installation of dredges, which was continued in 1912, as in the previous year. The data at hand indicates that in 1912 about 40 dredges were operated in Alaska, besides a number of others under construction. Of these, three are in the Fortymile district, one in the Fairbanks district, one in the Birch Creek district, one in the Iditarod district, one on the Kenai Peninsula, and the rest on Seward Peninsula.

There has been no change since the previous year in the opening of coal fields. One coal mine was operated for a part of the year at Chignik, in the Alaska Peninsula, and the mining of coal for local use was carried on in a small way at several other localities. Investigations were made in the Bering River coal field under the joint auspices of the Navy Department and the Bureau of Mines, to determine the availability of coal for naval use. One well was drilled at Katalla, and there was a small production of petroleum from this field, the oil being refined near the well, and the gasoline disposed of in the local market.

Transportation.—Except for the continuation of the work of the Alaska Road Commission in the building of wagon roads and trails, there was no marked improvement in transportation facilities during the year. The total railway mileage for Alaska in 1912 is 465, the same as in the previous year. Most of the railways were operated, except those in Seward Peninsula. The Copper River and North-western was blocked by landslides for about six weeks in the early fall.

In accordance with an Act of Congress, the Alaska Railway Commission was appointed about the 1st September, and spent about three months in the territory investigating railway routes and conditions of transportation. The report of this commission is in preparation.

Gold-Lode Mining.—It is estimated that there were about 22 gold-lode mines in Alaska that made some production in 1912, compared with 18 in 1911. In addition to this, development work was done on many lode prospects widely distributed over the territory. The value of the output from the auriferous lodes in 1912 is believed to be about $4,600,000, an increase of about $400,000 over that of the previous year. This increase must in large measure be credited to the Treadwell group of mines, but there was also a considerable production from various small properties in different districts.

South-Eastern Alaska.—The most notable mining advances in the territory during the year were those in the Juneau district. The Treadwell Mine increased its gold output. Work was continued on the 6,000-foot tunnel of the Alaska-Juneau Mine, and was begun on an adit tunnel of the Alaska-Gastineau, which will be about two miles in length. This tunnel is to undercut the Perseverance Mine, which, with adjacent properties on Sheep Creek, has passed under one management. The ore is to be carried to a mill of 6,000 tons daily capacity, which is to be erected at Tidewater. These enterprises, together with the continuation of work on the Kensington Mine and the reopening of the Jualin Mine, in the Berners Bay district, constitute an assurance that the production of gold in Alaska will not fall off, even aside from the promise of a larger output from other parts of the territory. It is reported that discoveries of rich gold-bearing quartz veins have been made on Funter Bay, Admiralty Island. Two mines were operated in the Sitka district, as in the previous year, and the discovery of a new gold-bearing quartz vein in the district is reported.

There was considerable advance of auriferous lode mining in the Ketchikan district during the year. The Goldstream Mine was again operated, supplying a 5-stamp mill. A 10-stamp mill was installed at the Valparaiso Mine. Two adit tunnels were started to intersect an auriferous quartz vein on the Buggy property, near Smugglers Cove. It is reported that the Lon de Van Company intersected an auriferous galena-bearing vein, at a depth of 1,100 feet, on its property located on Georges Inlet.

Prince William Sound.—The Cliff Mine, of the Valdez district, continues to be the only gold-lode property in the Prince William Sound region, which has made a considerable output. In the aggregate, however, considerable ore has been recovered from other properties incidentally to development work. At the Cliff the opening of the fifth level is the most important development of the year. Sinking was done on the Alice property, at Shoup Bay, and preparations made for installing a mill. Development work was also continued on the Mayfield property, about nine miles from Shoup Bay, near the Columbia Glacier, where an ore

body has been opened on two levels. At the Ramsay and Ruthford property, east of the Valdez Glacier, a mining plant was installed and considerable development work accomplished, the ore being opened to a depth of 90 feet below the outcrop. There was much prospecting in the northwestern part of Prince William Sound and vicinity. Port Wells, and the adjacent fiords. Accounts from this district indicate that the ores are similar to those of the Valdez region. Considerable development work was accomplished on several properties in this field.

Kenai Peninsula and Willow Creek Districts.—Work was continued on the auriferous lodes of Kenai Peninsula and the Willow Creek district. Three small mills, two on Falls Creek and one on Porcupine Creek, were operated for a part of the year. In addition to these, two arrastres and one prospecting mill were operated in the Moose Pass district. Considerable work was also done on properties on Porcupine Creek, near Seward, and on Palmer Creek, near Sunrise. A gold-lode prospect was opened near Bird Point, on Turnagain Arm, and a small shipment of ore for testing was made. Three mills were operated in the Willow Creek district, and development work was advanced. It is reported that two of these properties are to be consolidated and opened on a large scale. The information at hand indicates that several promising discoveries of auriferous lodes were made in this district during 1912.

Fairbanks District.—Although the output from the Fairbanks placers has decreased, there was far greater activity in lode mining and prospecting than in the previous year. Most of the operations were conducted on a small scale, and the total output of gold was not large, but a very considerable amount of development work was accomplished during the year. In 1912 six stamp mills, aggregating 24 stamps, were operated for a part of the year, and six other mills were being installed in the late summer, and some of these were put into commission before the close of the year. Statistics at hand indicate that the average recovery of free gold from these operations is about $50 a ton. In only two places are the concentrates being saved, though they undoubtedly contain additional gold.

Lode prospecting has continued with increasing activity during the year, and probably more than 200 men were engaged in this work. As a result a number of quartz veins were disclosed, some of which promise well. The notable features of the lodes are their great number, small size, and high tenor. Most of the veins from which free gold can be obtained by panning are composed almost entirely of quartz, with sulphides either absent or present only in subordinate amounts. Stibnite is the most common of the sulphides. Most of the veins have been discovered in two areas—one stretching east and west from Pedro Dome, and the other in the vicinity of Ester Dome. It seems probable, however, that this distribution may be accounted for by the localization of the prospecting rather than by the actual limitations of the distribution of auriferous veins. But few of the richer veins so far discovered are more than one or two feet in width, and the gold is, as a rule, confined to the vein itself. In some places, however, gold has been found in adjacent mineralized country rock. In general the results obtained by the work of the year have been satisfactory. No large veins have been discovered, but a large number of small ones have been found. The development has been largely carried on by local ,capital, and most of it has been well advised.

Lode Mining in Other Districts.—The influx of prospectors into the Innoko-Iditarod region during the last two years has stimulated the search for lode deposits, but little has yet been accomplished in actual development. In 1912 an auriferous quartz deposit was opened on Gaines Creek and a small mill was installed. This operation has been successful, and is an indication of the possibilities of lode mining. More important is the fact that many other metalliferous veins have been found, and that the geologic conditions are favorable to their occurrence in considerable areas of the Innoko basin and adjacent portions of the Kuskokwim basin.

The Apollo Mine, on Unga Island, continued in 1912 to be the only productive lode mine in South-Western Alaska. Some work was continued on lode prospects in the Iliamna region, notably on the Duryea silver-lead deposit.

There was but little advance in quartz mining during 1912 in Seward Peninsula. Some prospectng was done, as well as assessment work, on a large number of claims. The New Era Mining Company opened a quartz lead near Snow Gulch, where a 4-stamp mill has been installed. Considerable ore was also treated at the Nome custom mill. Plans have also been made to install a stamp on a property located near Bluff, 60 miles east of Nome.

Copper Mining.—The increased copper production of 1912, compared with 1911, is to be credited to the Chitina and Prince William Sound districts. The rise in the price of copper led to much prospecting and deadwork in these as well as in other districts.

The Jumbo and Rush and Brown Mines were the only considerable shippers of copper ore in the Ketchikan district. It appears that the Mount Andrew Mine was idle for most of the year, but plans have been formulated for systematic development. Developments were continued on the It, the Red Wing, the Vittory and the Lhote and Sanford properties, and steps were taken looking to the reopening of the Copper Mountain Mine. Some work was also done on a copper-bearing vein at Sum Dum, in the Juneau district.

The Kennicott-Bonanza Mine is the only one in the Kotsina-Chitina district from which shipments were made in 1912, but a large amount of development work was done on other properties. The concentrator installed in 1911 at the Bonanza Mine was operated during 1912. At the east end of the field work was continued on the Mother Lode, Nikolai, and Westover properties, and also on a property located on an island in the Kennicott Glacier. Prospecting and developing were especially active in the vicinity of Kuskulana River. Here the largest operations were those of the Great Northern Development Company, which completed about 5,000 feet of development work. The Alaska Consolidated Copper Company carried on development work on Nugget Creek and on the Rarus group of claims. The Alaska United Copper Exploration Company continued work on the Blackburn group of claims, located on Porcupine Creek. In addition to the above, a large number of claims were being opened in the Kuskulana region during the summer of 1912. This field is now readily accessible from the railway, and a branch has been surveyed which would permit the shipment of ore.

On Prince William Sound shipments were made by the Ellamar Mining Company, the Threeman Mining Company, the Landlocked Bay Copper Mining Company, and the Beatson Copper Company, located on Latouche Island. In addition to productive properties, there were a large number of claims on which development work was carried on, some of which give promise of soon reaching a shipping stage. A notable advance was that made on the Solomon Gulch property, near Valdez, where a force of men engaged during the year in opening a chalcopyrite ore body.

But little advance was made in copper prospecting in those inland districts, which are far from transportation. About 25 men are said to be carrying on prospecting and as-

sessment work in the White River region, and there are also some in the Nabesna district. Prospectors report the finding of copper ore on Sheep Mountain, in the Matanuska Valley. Some copper ore has also been found on a tributary of the McLaren River, in the headwater region of the Susitna. A little development work was also continued on the copper prospects of the Iliamna region, in South-Western Alaska.

Tin.—The dredge which was installed on Buck Creek last year was operated throughout the open season of 1912. It is currently reported that the output of 1912 is much larger than that of 1911. The Lost River lode-tin property has been bonded, and is now being systematically developed The results of these operations in 1912 are reported to justify further investments and the installation of a mill. This property promises to become the first productive lode-tin mine in Alaska.

Placer Mining.—The returns from the Alaska placer mines are far from being complete, but the information at hand indicates that the value of the output in 1912 was half a million dollars less than that of the previous year. This decrease in production is due to the fact that the output from the Fairbanks and Innoko-Iditeraod regions was considerably less in 1912 than in 1911. On the other hand, a discovery of rich placer ground was made in the Koyukuk district, and promising finds were made in the Ruby district and the Innoko-Iditerod region. Moreover, the two years' work brought additional proof of the adaptability of the dredge for placer mining in different parts of the territory.

No noteworthy changes took place in the placer mining districts along the Pacific seaboard, which are relatively unimportant. A little mining was done at Juneau, and some larger operations were carried on in the Porcupine district. Beach mining continues to employ a score of men at Yakataga, and probably as many more in South-Western Alaska, notably on Kodiak Island.

The season in the Nizina district was successful, except for the floods which occurred in the latter part of the summer, and caused much damage to the two large plants there installed. The plant on Chititu Creek was, however, put into working order again before the close of the season. Mining continued as in previous years in the Chistochina district, but was considerably less in the Valdez Creek district, chiefly because a large number of claims were under bond to a company which proposed to install a large hydraulic plant.

Hydraulic operations were continued on Kenai Peninsula and at Crow Creek, as in previous years. A dredge installed in 1911 was operated on Kenai River for part of the season of 1912. There was also considerable prospecting in this part of the field for dredging ground.

It is reported that the Yentna district had a very prosperous season. Notable increase in production was made on Dollar Creek, where some high gravels were developed. A few prospectors continue work in the Mulchatna region, west of Lake Clark, but no important discoveries have been made in this field.

Yukon Basin.—The Fairbanks district continues to lead in the production of placer gold. The new discoveries in this field were principally those on creeks which have already yielded some gold. The most important was on Eva Creek. The work of the year has also considerably increased the area known to be underlain by workable gravels in the Chatanika Flats, near the mouth of Dome and Cleary Creeks. Additional gold-bearing gravels are said to have been found on Fairbanks Creek. The Fairbanks Creek dredge was operated throughout much of the open season. The gold produced at Fairbanks came chiefly from Goldstream Creek, the lower parts of Dome and Cleary Creeks, and Ester, Eva, and Fairbanks Creeks. It is estimated that between 130 and 140 different plants were operated, and that from 900 to 1,500 men were employed. Summer operations were much in excess of those of the winter.

In the Circle district the placer gold was taken chiefly from the mines of Mastoden, Deadwood, Eagle, Mammoth, Switch, and Independence Creeks. It is estimated that about 27 mines were worked during the winter and 32 in the summer of 1912, employing from 60 to 100 men in the winter and from 145 to 175 in the summer. A dredge installed on Mastoden Creek was operated during the summer of 1912. Hydraulic plants were operated on Mammoth, Mastoden, and Eagle Creeks.

The Fortymile district had a successful season. Three dredges were operated there during the summer. It is estimated that about 25 mines were operated in the winter of 1912, and about 50 during the summer. Many of these were, however, only small plants.

It is reported that the Koyukuk district had a very successful season in 1912, but details are lacking at this writing. A large amount of gold is said to have been taken from the newly discovered deep placers of Hammond Creek, and this production may have been sufficient to more than double the output of the district, compared with previous years.

Though the current reports from the Ruby Creek district have been rather discouraging, yet it seems certain that this district will become a gold producer of some importance. In 1912 operations were practically confined to six creeks, all lying within a small area about 25 miles south of the town of Ruby, on the Yukon. The creeks on which productive mining has been carried on are Long Creek, Upper Long Creek, Bear Pup, Midnight Creek, Glenn Gulch, and Trail Creek. About 150 men were employed in this district on 30 claims, and the value of the gold production was probably in excess of $150,000.

About 24 claims, located on five creeks and employing 140 men, were worked in the Innoko district during 1912. No new discoveries were made. In the Iditarod district Otter and Flat Creeks continue to be the most important producers of placer gold. Work was also done on Chicken, Willow, and Happy Creeks, and a little mining was carried on about Moore Creek, located about 30 miles farther east. A dredge was installed on the upper part of Flat Creek during the winter of 1912, and was operated for the latter part of the open season. It is estimated that 34 mines were operated in the Iditarod district in 1912. These were distributed on six creeks, and employed about 650 men. Of these plants one is a dredge, eighteen are equipped with steam machinery, and the rest are operated by manual methods.

During the summer of 1912 gold was discovered on Fox Gulch, a tributary of Cripple Creek, 30 miles north-east of Ophir, which created considerable local excitement. About a hundred men are said to be prospecting in this field. It is reported also that some workable placers were found on Mud River, a north-westerly tributary of the Innoko.

Prospecting continued in the Aniuk River basin, where gold was found in 1911. A small amount of productive mining was done in this region in 1912. Nothing of importance has developed in the Goodnews Bay region, where several claims, however, were operated in 1912.

Gold Dredging on Seward Peninsula.—There was no abatement in dredge installation on Seward Peninsula in 1912. It is reported that during the year 39 dredges were completed or in process of erection. The dredge season began in May, but most of the machines were not operated until the first steamers brought in the dredge crews, about June 15. Information at hand indicates that by August some 30 dredges were in operation, and that a number of others were started before the close of the season. Dredging con-

tinued until about the middle of October. It is a significant fact that these dredges are widely distributed over the peninsula, some being operated or under construction in every district which has yielded placer gold. This brings the final proof that profitable dredging ground is by no means confined to the vicinity of Nome, to the Solomon River valley, or to the vicinity of Council, as at first believed. The limitations on profitable dredging seem to be controlled rather by the cost of transportation, and especially of fuel, than by the physical condition of the gold-bearing gravels. Another significant item is that, in spite of the drought of the early part of the summer, and the fact that the value of the winter clean-up was only $400,000, the production of gold for the season was nearly the same as that of the previous year. This indicates that a large part of the gold production came from dredging operations which were not seriously hampered by small water supply. It is fair to assume, therefore, that the production of placer gold from the peninsula has passed its minimum for many years to come.

EFFECT OF ELECTRIC CURRENT ON CONCRETE.*

During the last few years attention has been called to the possibility of damage to reinforced concrete structures by stray currents from electric railways and other power sources. The laboratory experiments of Toch, Knudson and Langsdorf, in 1906 and 1907, showed quite clearly that under certain circumstances the passage of electric current from the reinforcing material out into the concrete gave rise not only to serious corrosion of the reinforcing material but also to cracking and disintegration of the surrounding concrete. Since then numerous laboratory experiments have been carried out by various investigators, all tending to confirm the earlier observations in regard to the destruction of the concrete, but giving rise to numerous conflicting theories as to the cause of the phenomena observed.

Following the early demonstrations of the possibility of damage to concrete by electric current, reports of serious damage to certain concrete buildings, bridges, etc., have been circulated from time to time, and considerable apprehension has been aroused in some quarters that great damage may be in progress due to this cause. The subject was brought directly before the U.S. Bureau of Standards by numerous letters of inquiry from engineers, contractors and corporations, requesting information in regard to the probable extent of the damage and the most feasible methods of preventing it. Although a good deal of work has been done showing that under certain conditions, readily produced in the laboratory, blocks of reinforced concrete could be completely destroyed by electric current, there remained a wide diversity of opinion as to the cause of the phenomena observed. Recognizing the great practical importance of the subject, and acting in response to requests from numerous sources, the Bureau of Standards has since the summer of 1910 been conducting a thorough investigation of the cause and extent of damage to concrete by electric current and the best methods of mitigating the trouble under practical conditions.

The investigation has been conducted along the following lines:

(1) Laboratory studies of the cause and nature of the phenomena caused by the passage of electric currents through concrete.

(2) Observation in the field with the view of establishing definitely the probable extent of the danger in practice and the circumstances under which trouble is most likely to occur.

(3) A study of the various possible means of mitigating trouble from this sourse, leading to specific recommendations based thereon.

The reports of previous investigators that the passage of current from an iron anode into normal concrete caused destruction by cracking were only partly confirmed. This effect did not occur in most of the specimens tested when the potential gradient was less than about 15 volts over a distance of 3 in. or about 60 volts per foot of anode.

Among the numerous theories that have been advanced for the cracking, the one which attributes it to oxidation of the iron anode following electrolytic corrosion has been fully established. The oxides formed occupy 2.2 times as great a volume as the original iron, and the pressure resulting from this increase of volume causes the block to crack open. The mechanical pressure developed at the iron anode surface by corrosion of the iron has been found to reach values as high as 4,700 lb. per square inch, a value more than sufficient to account for the observed phenomena of cracking. Metals which do not form insoluble products of corrosion and all non-corrodable anodes never cause cracking of the concrete as a result of the passage of an electric current.

Suggestions of some engineers that copper-coated steel, or aluminum, be used as reinforcing material have been shown to be impracticable, since the copper coating is readily destroyed and the aluminum is attacked by the alkali in the concrete.

The corrosion of iron anodes in normal concrete is very slight at temperatures below about 50 deg. Cent. The lack of corrosion of the iron at temperatures below about 50 deg. is due to the inhibiting effect of the hydrated lime, $Ca(OH)_2$, in the concrete. For any fixed temperature the amount of corrosion for a given number of ampere hours is independent of the current strength.

The rapid destruction of anode specimens at voltages from 60 to 100 volts or more is made possible mainly by the heating effect of the current, which raises the temperature above the limit mentioned above. If the specimen be artificially cooled no appreciable corrosion occurs and no cracking results.

In the specimen tested the potential gradient necessary to produce a temperature rise to 50 deg. Cent., with consequent corrosion, was about 60 volts per foot. For air-dried concrete it is much higher. This shows that under actual conditions corrosion from stray currents may be expected only under special or extreme conditions.

Since the passivity of iron in concrete is due chiefly to the calcium hydrate present it appears probable that old structures, in which the hydrate has been largely converted into the carbonate, will be more susceptible to the effect of electric current than the comparatively new concrete with which the foregoing experiments have been made. The increase in the corrosion would, however, be partly offset by the increase in the resistance of the older concrete.

The addition of a small amount of salt to concrete, as is frequently done to prevent freezing while setting, has a twofold effect. First, it greatly increases the initial conductivity of the concrete, thus allowing more current to flow, and, second, it destroys the passive condition of the iron at ordinary temperatures, thus multiplying by many hundreds of times the rate of corrosion and consequent deterioration of the concrete. Salt should, therefore, never be used in structures that may be subjected to electrolytic action. Further, reinforced concrete structures built in contact with sea

*Abstract of paper delivered before National Association of Cement Users, Pittsburg, December 10th-13th, 1912, by Mr. E. B. Rosa, Assistant Director; Mr. Burton McCollum, Associate Physicist, and Mr. O. S. Peters, Assistant Physicist, U.S. Bureau of Standards.

water or in salt marshes are very susceptible to trouble from electrolysis.

Specimens of normal concrete carrying currents increase their resistance an hundredfold or more in the course of a few weeks, which fact still further lessens danger of trouble. The rise of resistance is in general due to the precipitation of calcium carbonate within the pores of the concrete, thus plugging them up. A slight amount of salt prevents this precipitation and consequent rise of resistance, thus still further emphasizing the detrimental effect of the presence of salt.

Contrary to the observations of previous investigators, a distinct softening of the concrete near the cathode was observed. This begins at the cathode surface and slowly spreads outward, in some cases ¼ in. or more. After exposures to the air this softened layer becomes very hard again, but remains brittle and friable. This softening effect causes practically complete destruction of the bond between the reinforcing material and the concrete, reducing it to a few per cent. of its normal value. Unlike the anode effect, which becomes serious in normal concrete only on comparatively high voltages, the cathode effect developes at all voltages, the rate being roughly proportional to the voltage in a given specimen. For this reason it may frequently occur in practice, and is, therefore, a more serious matter practically than the anode effect about which so much has been heard.

The softening of the concrete at the cathode is due chiefly to the gradual concentration of sodium and potassium near the cathode by the passage of electric current. The alkali in time becomes sufficiently strong to attack the cement. This action can be increased or diminished by varying the sodium and potassium content of the cement.

Observations have shown that the softening of the concrete only takes place very close to the cathode, the main body of the concrete remaining perfectly sound without loss of strength. Because of this effect the method of protecting reinforced concrete buildings by connecting the reinforcing material as a cathode to a battery or booster would be much more dangerous than no protection at all.

The only effect which an electric current has on unreinforced concrete is to cause a migration of the water soluble elements. Consequently, in the absence of electrodes, the ultimate effect of current flow on the physical properties of the concrete is not materially different from that of flow water seepage, which also removes the water soluble elements. Non-reinforced concrete buildings are therefore immune from trouble due to stray earth currents.

Conditions do arise in practice which will cause damage from stray currents, but the danger from this source has been greatly overestimated in many quarters. While precautions are necessary under certain conditions, there is no cause for widespread alarm. Waterproofing reinforced concrete would greatly increase its resistance and diminish accordingly the danger from the anode or cathode effects. Waterproofing to prevent electrolysis is, however, a much more difficult matter than waterproofing to maintain a moderate degree of dryness, because of the much higher degree of waterproofing required in the former case. It has been found that practically all of the waterproofing agents now on the market that are intended to be mixed with the concrete are of little value as preventives of electrolysis. Waterproofing membranes, however, when applied to the surface can be made much more effective and may have considerable effect in preventing the entry of earth currents into the concrete.

Painting or otherwise coating iron with an alkali resisting metal preservative before embedding it in concrete may serve to minimize the dangers of electrolysis, but no such coating has been found that does not prevent the formation of the bond between the concrete and iron when the concrete sets. In order to insure safety from electrolysis potential gradients must be kept much lower in structures exposed to the action of salt waters, pickling baths and all solutions of chlorides, sulphates, nitrates or carbonates.

All electric power circuits within the building should be kept free from grounds directly on a portion of the building itself. If the power supply comes from a central station the local circuits should be periodically disconnected and tested for grounds and incipient defects in the insulation. In isolated plants ground detectors should be installed and the system kept free from grounds at all times.

All pipe lines entering concrete buildings should, if possible, be provided with insulating joints outside the building. If a pipe line passes through a building and continues beyond, one or more insulating joints should be placed on both sides of the building. If the potential drop around the insulated section is 8 or 10 volts or more, the insulated portion should be shunted by means of a copper cable. The grounding of electric conduits to water pipes and ground plates is in general not to be recommended in the case of concrete structures.

Lead-covered cables entering such buildings should be insulated from the concrete. Wooden or other non-metallic supports which prevent actual contact between the cable and the concrete will give sufficient insulation for this purpose. Such insulation of the lead-covered cable is desirable for the protection of the cable as well as the building.

In making a diagnosis of the cause of damage in any particular case the fact that a fairly large voltage reading may be obtained somewhere about the structure should not be taken as sufficient evidence that the trouble is due to electrolysis. The distance between the points and particularly the character of the intervening medium are of much greater importance than the mere magnitude of the voltage reading. As a precautionary measure, however, all potential readings about a reinforced concrete structure should be kept as low as possible.

SPECIFICATION FOR CEMENT TOP FLOORS.

This specification is for laying hard-finish cement top floors on new rough concrete, either paling or slabs supported by forms.

Finish to be mixed one part of cement to two parts crushed trap rock or hard gravel screening, which will pass through a half-inch sieve, and from which the fine dust has been removed. This is to be thoroughly mixed in a mixing box or by machine mixer, with an amount of water to produce a plastic but not a sloppy consistency; spread on the under-concrete before either the finish or the under-concrete has had time to set, floated with a wooden float to a true level, and then lightly troweled with a steel trowel as soon as possible to bring it to proper level, and smooth the top slightly. This will give a finish which is pebbly. It will not be dead smooth or slick like a sand finish.

After the finish has been troweled and has set sufficiently so that the covering will not mar the surface, it should be covered with sawdust, sand, cloths, or any other material which will hold water on it continuously. In building reinforced concrete work difficulty will be caused by the sand and sawdust blowing about the work, filling the forms, and generally getting in the way. In working around a textile mill there is usually plenty of old bagging, and in a paper mill there is usually plenty of old felts which can be borrowed for the purpose of preventing this.

The finish shoud be kept soaking wet for at least a week, or, better, for ten days. After two days it is possible to put up studs and do miscellaneous work on top of the new finish, provided it is not allowed to dry out.

COAST TO COAST.

Victoria, B.C.—The amount expended by the Dominion Government in dredging in the harbor of Victoria totals $84,194.21.

Calgary, Alta.—Up to Christmas, ninety-five applications had been received by the municipal authorities for the position of city engineer.

Calgary, Alta.—Permission is to be asked from the provincial government to allow Calgary to issue debentures payable in fifty years for certain purposes which include purchases of real estate, concrete structures and buildings which will come under the first-class regulations.

Ottawa, Ont.—The Department of Customs has issued an order prohibiting the importation from the New England States of forest plant products, including logs, tan bark, posts, poles, railway ties, cord wood and lumber, unless accompanied by a certificate from the United States Department of Agriculture that such products are free from the gypsy moth.

Berlin, Ont.—The report of the year's operation of the street railway shows a credit balance of $6,031.11, after taking off the debenture and interest payment. Ten per cent. was written off for depreciation on machinery, 5 per cent. on rolling stock, and 3 per cent. on trackage. This leaves a net profit of $910.58. Of that amount Waterloo is entitled to $227.64 and Berlin $682.94.

Winnipeg, Man.—According to the report just issued by the chief engineer of the Grand Trunk Pacific Railroad, on the work accomplished for the past year, construction has been undertaken on 563 miles of main line, and on 688 miles of branch lines, making a total of 1,251 miles of line on which clearing, grading, and track-laying have been done. Track has been laid on 128 miles of main line, and on 331 miles of branch lines, making a total of 459 miles of railway completed exclusive of second tracks and sidings.

Montreal, Que.—Owing to the many cases wherein expert engineering advice is required as regards level crossings, the elevation of tracks, and the construction of tunnels, the Board of Control of Montreal had under consideration recently the advisability of engaging an expert engineer for that purpose. The matter was deferred till the beginning of January, when it is most likely favorable action will be taken. Another reason for the engagement of a special engineer is that the regular staff of engineers at the city hall have practically no time to take up such work, as they have all and more than they can accomplish in keeping up with the demands for new municipal public works. Every season the city has important cases to be argued out before the Railway Commission, involving large sums of money and experience has taught the municipal authorities that the promoters have the best technical advice available. The corporation will now proceed to secure the services of an engineer who will undertake such work as the board may direct him to look after.

PRINCE RUPERT HARBOR.

It will take probably ten years to complete the work planned for the improvement of Prince Rupert harbor. Under instructions from the Grand Trunk Pacific Railway, Engineer Virgil B. Bogue has had his staff working here for several months, in preparation for making this a model harbor with its fourteen miles of length, thirty miles of water front, and a mean depth of 60 feet, without a rock or bar to interfere with navigation. Mr. Bogue plans to add civilization to its natural advantages and make a subharbor of fresh water 40 square miles in area. Between the island on which Prince Rupert is located and the main land is a large salt water lake with narrow passages at each end. Part of the general plan of harbor improvement is to put locks at the passage ways and to convert the lake into a fresh water harbor fed by mountain streams, and at high tide level. The whole water front is being laid out to accommodate berths for the big ocean liners, shipyards, fishing plants, lumber yards, saw mills, ore docks, elevators, warehouses, and other industries. The plans are sufficiently comprehensive to accommodate all the requirements of a city of several hundred thousand people.

FORESTRY AT TORONTO UNIVERSITY.

The Faculty of Forestry, University of Toronto, which graduated twelve students last year, has in the registration for the present academic year filled up its ranks to the number of 44, two old students who had interrupted their course returning and 17 new ones being registered. The graduating class has ten names, the first year of the four-year course eight names, the second year ten, and the third year five, besides eight in the six-year course in various years, and three occasional students.

Most of the graduates found employment with the Forestry Branch of the Dominion Department of the Interior, and a few with the Canadian Pacific Railway Company.

The call for foresters, owing to the sudden organization of the British Columbia Forest Branch, has been so urgent that the Dominion Branch has not been able to retain all its men, and a number have joined the new department. The market for foresters has been brisk, with consequent raises in salaries to an unusual level for young men, and altogether a hopeful development for employment is anticipated.

There have been no essential changes in the curriculum as followed hitherto, except that the practice camp has been held at the beginning of the session instead of at the end.

An unusually satisfactory location for the camp was found at Frank's Bay, Lake Nipissing, Ontario, where an old depot of the John B. Smith and Sons Lumber Company was at the disposal of the fifteen students who attended the camp, with two instructors, and a virgin stand of red pine (limits of the Strong Lumber Company), to be logged this winter, together with other types, gave excellent opportunity for practice work in forest survey, and gathering data for working plan, studying detail of types, constructing growth tables, etc.

The work was carried out according to careful plans, and has been so complete and satisfactory with regard to red pine growth studies that it is expected to publish the results.

VICTORIA'S OFFICIALS REPLY TO UNDERWRITERS.

Water Commissioner Rust and Fire Chief Davis, of Victoria, find that so far as the water situation in the city at present is concerned, the recent statements of Mr. Page, secretary of Vancouver Island Fire Underwriters, were about right, and they admit that there is a shortage of water, which shortage will be more acute during the coming summer; in fact, until water is obtained from Sooke lake. But the water commissioner is now preparing a report which will deal with the best means of augmenting the supply pending the completion of the Sooke lake development work, and this report will shortly be before the council.

They correct Mr. Page's statement that the fire department has been in the practice of connecting fire engines to the salt water hydrants. It was only done on one occasion, about two years ago, but the standing order now is that this must

not occur. Also, relative to the department's telephone service, the department lines are operated under a separate exchange system in headquarters station, with a private wire for fire alarms only. Further, Mr. Page's suggestion that a fire alarm wire to the North Dairy Farm pumping station is required has been adopted, and the line is about completed.

The officials' report also states that it is the intention of the water commissioner not to construct any more four-inch mains except occasionally on streets whereon there are a number of houses and in the outskirts of the city.

In answer to a question, Fire Chief Davis stated that for the past two months the pressure available for fire fighting purposes in Victoria West has been good. At the Victoria West fire hall, which is about the highest point in that section, the pressure has been maintained at from fifty-five to sixty pounds and has not been less, while on the low level the pressures range from ninety to ninety-five pounds, and have run as high as 105 pounds. This improvement has occurred since the Esquimalt Water Works Company installed its new main to Goldstream. About two months ago while repairs to the pipe line were being made, the supply was gradually reduced during the day, with the result that the pressure had been reduced to about twenty-five pounds.

ST. LAURENT AND MOUNT ROYAL FRANCHISES.

An ending somewhat characteristic of present-day developments has taken place in the case of the franchise for the public service of the municipality of St. Laurent and the disagreement between that municipality and the new Model City of the Canadian Northern Railway. It may be recalled that the Franco-Belgian Syndicate some time since obtained the franchise for the supply of water for the town but refused to post the deposit of $20,000, being no doubt desirous of obtaining the franchises for all the public services. Later, the council granted franchises for water supply, lighting and street railway service to the company, the conditions being that the franchise was for twenty-five years, work on the waterworks and on lighting to be commenced within thirty days of notice from the council, and the railway to be commenced within six months of the adoption of the by-law now before the legislature at Quebec.

The Franco-Belgian Syndicate only had a capital of $100,000, but was applying to the Dominion Government for an increase to $2,000,000, and the representatives of the company claimed they had lots of French and Belgian capital behind them and were well able to post their $50,000 deposit.

It was a little significant that the Montreal Tramways Co. was not making a very strong agitation against the granting of the franchise, so far as known. When the matter came up before the Quebec legislature, it developed that the Franco-Belgian Syndicate had turned over its franchise for street car service to the Montreal Tramways Company and its lighting franchise to the Montreal Public Service Corporation. These concerns are those with which Mr. E. A. Robert, M.L.A., is particularly interested and which are included as subsidiaries in the Montreal Tramways and Power Company. It was suggested that Mr. Robert should not vote in the matter when it came up at Quebec, but the point was not pressed for the reason that the government had a large majority in any case.

In the above connection, also, the legislature sanctioned a twenty-five year franchise for the Montreal Tramways Co. for the street car service for the Canadian Northern Railway "Model City," the name of which town was changed at the same sitting of the legislature to "Mount Royal." Also, at the same meeting, a fifteen-year franchise was given the Montreal Public Service Corporation for the lighting of the streets of Mount Royal. The counsel for the Montreal Light, Heat and Power Co. was on hand to object to this on various grounds, among which was the fact that no one yet lived in Mount Royal. He claimed that it was a shame that this company should get the exclusive franchise in this manner when there were so many other companies in the field. The answer made to this remark by the friends of the bill was that the Montreal Light, Heat and Power Co. should have thought of this when they were getting their privileges in 1901 and that if they were prepared to give up their exclusive franchises the other companies were prepared to do the same.

As a result of the final revision made by the private bills committee of the legislative assembly, the Montreal Tramways Company, and allied interests, abandoned their exclusive franchise for the construction of a water works system in the parish of St. Laurent, and retained the exclusive franchises for the tramways service, and the supply of electric light and power. These franchises are for the period of twenty-five years each. The protests of the electors of the parish of St. Laurent and the vote they had taken against the water works privilege being limited to one company, were not commented on in any way.

The legal representative of the company, Mr. Rinfret, moved that the reference to the water works by-law, which the bill asked to be sanctioned with the two other by-laws, be omitted, and this was followed by the further amendment, also included in the bill of Mount Royal in favor of the protection of vested rights.

Honorable Mr. de Varennes, chairman of the committee, inquired whether the representative of the parish of St. Laurent consented to the change, and Mr. Jasmine nodded consent.

The Vancouver board of trade is taking up matters of material benefit to the province as a whole, one of which is the question of securing actual settlers for the land. There has been criticism of the manner in which the land resources of the province have been administered, and the board of trade committee have had the matter under consideration for months. The substance of its report is that care should be taken to exclude the speculator, to encourage the settler and to help the man who would till the soil, practical assistance being given by the government.

PERSONAL.

R. A. ROSS, consulting engineer, of Montreal, has been engaged by the city of Calgary to make a report on the local power and light situation.

H. A. BAYFIELD, government superintendent of dredging in British Columbia, has been relieved of his duties by the Minister of Public Works.

ALEXANDER POTTER, consulting engineer, New York, has changed his address from 114 Liberty Street to 50 Church Street, New York City.

H. BARBER has resigned from the Hydro-Electric Department of the city of Hamilton to take a position with the Toronto Hydro-Electric Commission. Mr. Barber is a graduate of the Toronto University in Electrical Engineering.

JOSEPH D. EVANS, who has been chief engineer of the Montreal Tramways Company since June, 1911, will sever his connection with that company on January 1, and become construction manager of the Electric Bond and Share Company, of New York, one of the largest builders and operators of public utilities on the continent.

J. W. TYRRELL, one of the first graduates of the School of Practical Science, has formed a new consulting engineering firm in Hamilton, Ont. The members of the

firm are J. W. Tyrrell, John E. Jackson and Oliver E. Blandy, and the work taken up will be civil engineering, and Ontario and Dominion land surveys. The offices are in the Hamilton Provident and Loan Company.

W. P. NEAR, B.A.Sc., has been appointed city engineer of St. Catharines, to take the place of Mr. R. D. Brown, whose resignation was noted in these columns some weeks ago. Mr. Near was born in St. Mary's, Ont. He was educated in the High School there, and later graduated in civil engineering from the University of Toronto. He worked on boundary surveys in Alaska, and later spent a year on the Temiskaming and Northern Ontario Railway. The year 1905 witnessed the eclipse expedition to Labrador and Mr. Near was a member of the party. Three and a half years ago he joined the main drainage department as a member of the Toronto city engineering staff.

COMING MEETINGS.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual Meeting will be held on Jan 28th, 29th, and 30th, 1913, at the Society's new headquarters, 176 Mansfield St., Montreal. Secretary, C. H. McLeod.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annua Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving: Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre: Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack: Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES—President, George Thompson, Indian Head, Sask.: Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer. J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary. H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

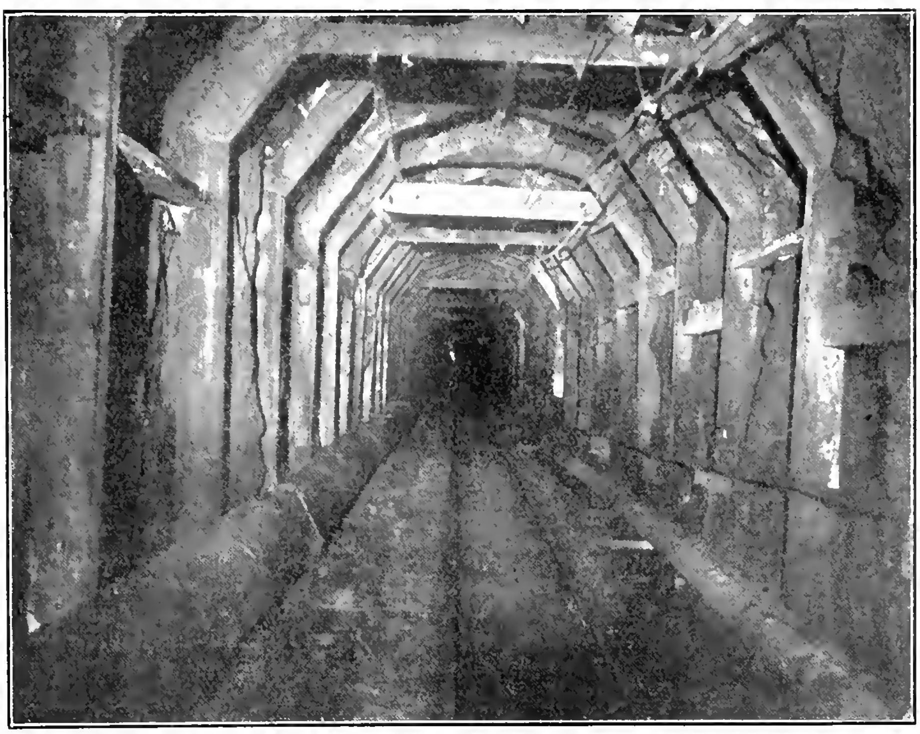
The Canadian Engineer

An Engineering Weekly

THE FINAL COMPLETION AND OPERATION OF THE LOS ANGELES AQUEDUCT.

The Los Angeles aqueduct, which for the past eight years has been under construction, is now nearing completion. Late in February the system should be completed and ready for operation. The enterprise has excited international attention; first, because of its magnitude; second, by reason of the unusual difficulties of operation which have been overcome; third, that with the exception of one comparatively small contract, all the work has been done by the municipality itself; fourth, that it is a public work which will be completed in advance of the time for which it was promised and at a cost well within the original estimate; fifth, the great economic value of the water for irrigation and domestic use and the development of hydro-electric power. In the following paragraphs each of these features will be discussed briefly, the object being to give a general description of the whole work, the economies of construction which have been worked out on a large scale and the economic importance of the enterprise to the whole of Southern California.



Interior of Elizabeth Tunnel.

(Photograph taken 2½ miles within the tunnel. Point of light in centre of picture is north portal of the tunnel)

The city of Los Angeles, a municipality of 400,000 population and growing at the rate of 40,000 per year, in 1904 was confronted by a diminishing water supply, at present obtained from the surface and subterranean flow of a stream called the Los Angeles River. No municipality has greater need for an abundant water supply, for it is situated in a semi-arid region where the average precipitation does not exceed 15.67 inches annually and no rain falls from April to the last of October. The per capita consumption of Los Angeles is 140 gallons daily; the daily per capita consumption of London amounts to only 28 gallons.

After federal and Los Angeles engineers had investigated the conditions for a period extending over several years, the nearest adequate source of supplementary supply was found to lie in the Owens River, a stream draining the eastern face of the Sierra Nevada Range which forms the roof-shed of the United States. To this source the city has gone. Purchasing 120 square miles of territory in the Owens Valley and with the active co-operation of the United States government in the way of public lands and helpful legislation, Los Angeles has undertaken to carry a daily supply of 280,000,000 gallons from this source into the Fernando Valley, at the mouth of which the city is situated.

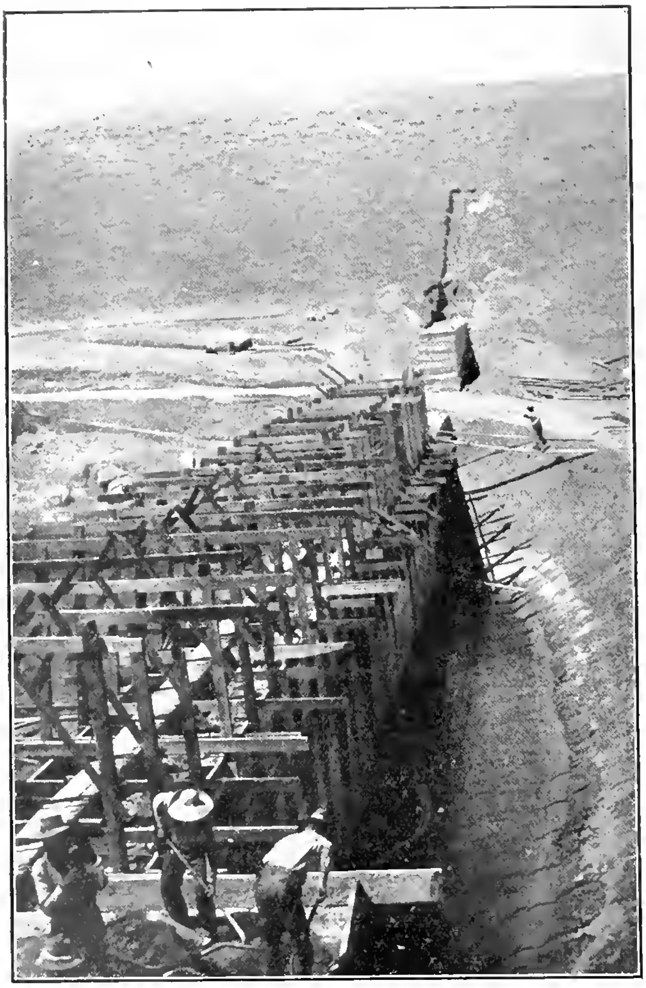
To accomplish her purpose the city is constructing a concrete aqueduct across the great Mojave Desert and under the Coast Range (Sierra Madre) of mountains. The aqueduct is reinforced by an extensive system of storage and regulating reservoirs. The length of the aqueduct from the intake to the impounding reservoir at the outlet is 234 miles. From the latter point the water will be distributed for irrigation or carried 10 miles further through steel force mains to be connected with the city's present waterworks. The system is gravity throughout. The intake is 3,812 feet above sea level; the outlet of the lowest reservoir is at elevation 1,020 and the elevation of the Los Angeles city hall is 276 feet above sea level. The total estimated cost of the aqueduct proper, exclusive of other features yet to be discussed, is $24,500,000. This, in a word, is the Los Angeles aqueduct, or, as it is quite popularly known, the Owens River project.

The economic value of the aqueduct lies in the fact that it will provide domestic water for 1,000,000 people; through

a municipal irrigation system irrigate 135,000 acres of land surrounding the city, and from its 1,500 feet of fall develop a maximum of 120,000 horse-power of electrical energy, for which funds have already been partially provided.

The foregoing briefly explains the impelling motives of the city in undertaking a work of such magnitude and the ultimate possibilities of the project. It is similar to the Panama Canal in that it is without a parallel in history.

It must be remembered that Los Angeles, to accomplish her purpose, went into a naked desert and among high and desolate mountains—a country practically devoid of habitation, fuel or water. The work of preparation in point of the spectacular outrivals the actual construction.



Building the Concrete Core-Wall of the Fairmount Reservoir.

Only the bare outlines can be given here, but the preparatory features included the construction of a standard gauge steam railroad 142 miles in length by the Southern Pacific Railroad Corporation, which secured thereby the hauling of the 20,000,000 ton miles of freight; the building of 315 miles of mountain roads and trails costing 260,000; the installation of three water systems comprising four reservoirs and 150 miles of mains at a cost of $350,000; the building of a municipal copper line of telephone system with 460 miles of lines and costing $75,000; the erection of three hydro-electric power houses and 268 miles of high-tension transmission line to furnish motive energy and light along the aqueduct zone at a cost of $450,000; the construction of a large number of structures of all classes and description for men, animals and machinery; and, finally the purchase of clay and limestone deposits and the erection of a municipal Portland cement mill with two auxiliary tufa grinding mills at a cost of $800,000. A little over $4,000,000 was expended before the work of aqueduct excavation was even started.

Since June of 1909, the excavation has continued at a rate exceeding 50 miles per year. To-day the excavation totals 220 miles. (This is approximate on the date at which I write—December 7th). Much of it has already been tested wherever water has been obtainable, and while no official date has been set for the dedication of the work, March 1st should see the finishing touches completed.

A tabulation showing the classification of the work, together with the total footage, is as follows:—

Classification.	Total footage.
Tunnel	42.69 miles
Power tunnel	9.23 "
Open unlined canal	21.14 "
Open lined conduit	39.56 "
Concrete-covered conduit	97.72 "
Haiwee By-Pass	1.92 "
Siphons (steel and concrete)	12.06 "
Flumes	.17 "
Power penstock	.44 "
Other power construction	.30 "
Reservoirs	8.5 "

Total length of aqueduct system 233.73 miles

The original design of the aqueduct, if the power was not developed, called for the use of the natural bed of the San Francisquito Canon for a distance of about 12 miles. Owing to the large asset in the power feature, hydro-electric power is to be developed simultaneously with the completion of the aqueduct so that instead of being permitted to follow the stream channel the water will be carried along the rim of the canon. This construction has been denominated as "Power" in the above classification and has been undertaken conjointly by the aqueduct and power bureaux, each bearing their pro rata of the expense. Denominated as "Division No. 14," this work was left to the last, as bonds for power construction were not voted until late in 1910. Otherwise the aqueduct might have been completed some months earlier than the date now set. Construction on this section was begun in August of 1911 and the last of the tunnels should be excavated shortly after the first of the year.

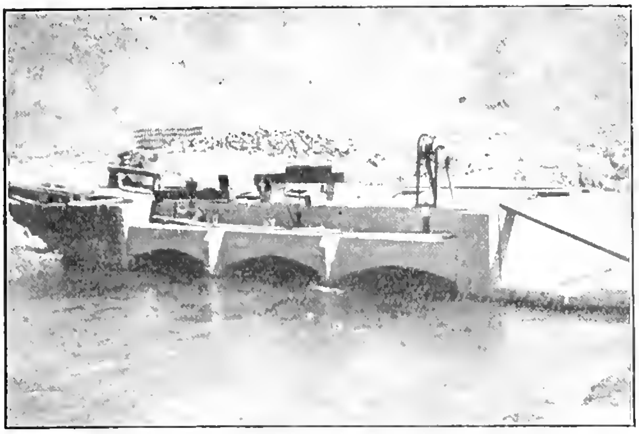
The system of reservoirs which is now under construction is one of the largest in existence. The Round Valley reservoir, with an impounding capacity of 340,890 acre feet, which will be situated 50 miles above the intake, will not be constructed until after the aqueduct is in operation. It has been designed solely for the storage of heavy years of precipitation as a safeguard against years of drought. The other reservoirs of the system are under construction and are as follows:—

Name.	Acre feet.
Haiwee	63,800
Fairmont	7,620
Dry Canon	1,325
Fernando (Lower)	25,000

Of the foregoing the Dry Canon reservoir is completed, the Haiwee is practically completed, while the Fairmont and the Fernando are well under construction. The dam of the Lower Fernando will be 700 feet wide at the base, 7,320 feet in length, 130 feet in height, and the fill amounts to 2,700,000 cubic yards. It is being built by sluicing and exclusive of the Gatun dam of the Panama Canal, will be the largest hydraulic filled dam in existence. This reservoir is at the terminus of the aqueduct and is calculated to afford four months' supply for one million population. Two other

large reservoir sites have been surveyed as a part of the general plan of irrigation, but no work has as yet been undertaken on their construction.

The most important phase of the work, in fact one of the controlling factors in the completion of the aqueduct, was the Elizabeth Tunnel. This tunnel was "holed" March 1st, 1911, nearly a year in advance of the estimated time required for its excavation. This tunnel, the second longest water tunnel in the United States, was driven 26,870 feet through the hard gneiss rock of the Sierra Madre range in



The Intake of the Los Angeles Aqueduct, Eleven Miles North of Independence, California.

the short space of 1,240 working days. The average rate of progress from each portal was approximately 12.36 feet per day. United States tunnel records were repeatedly broken, that of 449 lineal feet in a thirty-day month from a single heading being advanced to 604 feet for the same interval. The work was carried on continuously in three eight-hour shifts from opposite sides of the range, the excavation being accomplished with Leyner drills driven by compressed air, and the muck handled by electric motor railways. Throughout the task, the work, excepting at the very start, when crude methods were adopted until the arrival of proper machinery, the most modern electrical equipment was used. The underground and surface forces at each portal averaged 100 men throughout the drilling. From the north portal the progress was made exceedingly difficult by water pockets and swelling earth, and heavy timbering was required. From the north portal 13,500 feet were driven and from the south portal 13,370 feet. The centre lines of the tunnel met within 1⅛ inches and the grades checked to five-eighths inches. The estimate of cost for the completed tunnel was $75 per lineal foot, or $2,015,250. The actual cost of boring and concreting has been $50.69 per foot, or a total of $1,362,040, which is $653,210 below the amount set aside for the purpose. Concreting is now nearing completion.

Including the construction of the Elizabeth Tunnel, the tunnel work of the aqueduct until the first of this year has progressed at an average rate of one mile of tunnel excavation per month.

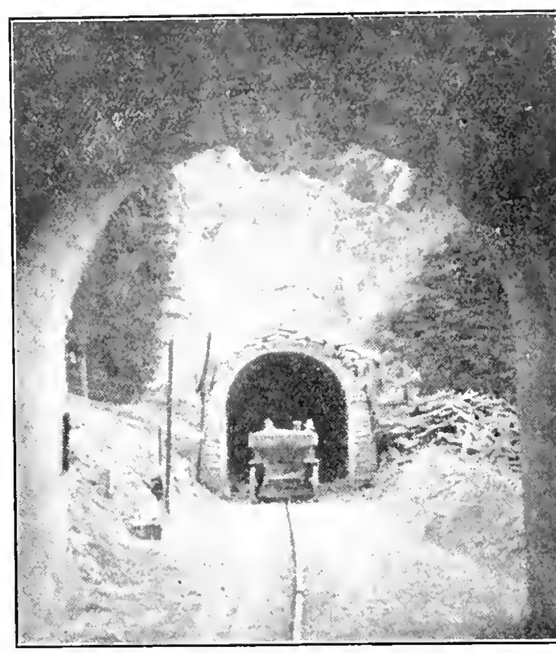
The mechanical excavating equipment for conduit and canal excavation consists of two powerful electric dredges which have now completed their work in the Owens Valley, 13 steam and electric power shovels and one giant excavator. The labor force has ranged from 2,500 to 4,300 men, during the summer season it being difficult to obtain laborers who were willing to go out on the desert.

The hospital department, as well as the commissary were let by contract, the city receiving no financial return and having the privilege of terminating the contracts upon 30 days notice if the city's standard of board, medical and sanitary care of men and camps is lowered. The men pay $1 per month for medical attendance and board is furnished at the rate of 30 cents per meal. Rates of pay for day labor have ranged from $2 to $2.75 for eight hours' work, depending upon the labor market as well as the character of the labor. Miners and mechanics have received from $3.50 to $3.75 for eight-hour shifts and formen $3.50 to $4.50 per day.

With the exception of one small contract representing three per cent. in point of distance and which was in easy construction, all the work has been done directly by city forces from engineers down to day laborers.

On this work, also, the city of Los Angeles for the first time in American municipal history inaugurated the bonus system of payment. Its success surpassed the most sanguine expectations of the city's engineers. Whether it is in conduit excavation, concrete lining, tunnel boring, siphon building or whatnot, the chief engineer sets as a basis of bonus payment, dependent upon the classification of the particular piece of work, the average progress that should be made by the crew or gang in a ten-day period. For all in excess of this amount, each man participating in the work, in addition to his daily wage, is paid an established sum proportionate to the progress made. On the Elizabeth tunnel, for example, miners were accustomed to receive monthly pay-checks which, with their bonus, ranged from $140 to $170, and muckers and other laborers' checks were in proportion.

This system has brought out the best that was in every man because, in the hope of personal reward, there has been an incentive for him to do his best. Moreover, it created a rivalry between each of the fifty camps and brought an organization of unusually high efficiency. As drones retarded



Showing Completed Tunnels.

the work, delayed progress and so cut down the bonus payment, the workers of their own accord drove out the drones. The working out and development of the system has excited a great amount of interest from engineering publications, engineers and municipal officials throughout the United States.

Another phase of unusual municipal activity in connection with this enterprise has been the building and operation of cement mills and the introduction and use of tufa cement. In this phase of the undertaking, $875,000 of the public

funds were expended. The Portland cement mill was erected at Monolith, close to the line of the aqueduct, about equidistant from the intake and outlet, adjacent to large deposits of limestone and clay and with transportation facilities that have reduced freight rates to a minimum. This mill was first fired in March, 1909, and with a capacity of 1,000 barrels per day, to January, 1, 1912, had ground 575,000 barrels.

It was found that at Monolith and two other points in close proximity to the aqueduct line there were large deposits of tufa strikingly similar to the Italian tufas used in the construction of the Coliseum and the Roman aqueducts. Tufa is a volcanic ash metamorphosed by volcanic heat and water into a white, brittle, porous rock. A year of tests and experiments demonstrated that an excellent cement could be manufactured by taking equal amounts by volume of Portland cement and ground tufa and regrinding them to a fineness of not less than 90 per cent. passing a 200 mesh screen. The seven-day test shows to the advantage of the Portland, but after that the tufa cement surpasses the Portland in breaking strength and at the end of one year, exceeds Portland by about 20 per cent. In 1909-10, therefore, tufa grinding mills with an aggregate daily capacity of 2,600 barrels were erected on the sites of the deposits.

Building a Concrete Siphon.

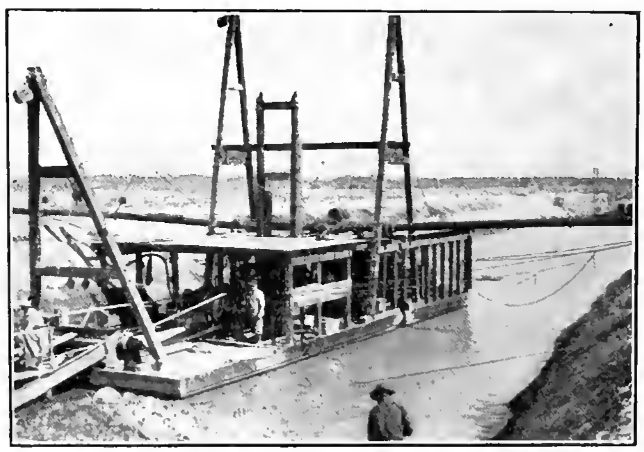
The advantage of this municipal move will be seen in a comparison of cement prices. At the time aqueduct work was started, commercial cement sold in the Los Angeles market at $2.25 per barrel. The city has been able to manufacture her own Portland cement at a cost of approximately $1.30 per barrel and the tufa cement at from 83 cents to 86 cents per barrel, besides reducing freight charges fully fifty per cent. by having two of the tufa mills directly on the aqueduct where the material was to be used. Now that the aqueduct is nearing completion the tufa mill machinery will probably be disposed of to the federal government, while it is possible that the Portland mill may be retained to furnish cement for other large public works now underway.

At the time this is being written, the most interesting phase of construction is the fabrication of the inverted steel siphons by which the waters of the aqueduct are to be carried across canons and valleys. So far as the writer knows, these huge steel pipes are the largest and longest in existence. They range in length from 611 to 15,596 feet, and in diameter from 8 feet 6 inches to 11 feet. The thickness of the steel varies from one-fourth inch to one and one-eighth inches. The aggregate length is 49,576 feet, the cost of which installed represents an expenditure of $1,400,000. The total tonnage amounts to 14,500 tons. These siphons will be under heads ranging from 75 to 450 feet.

The siphons are all of single plate construction. The material is furnished under contract and the work of erection is performed by the city. No foundry on the Pacific Coast was equal to the magnitude of the task. The plates are therefore rolled, punched and bevel-sheared, under the eyes of Los Angeles inspectors, in the steel foundries of Pittsburgh, Pa., and Camden, N.J. There they are erected section by section, given a number on a diagram showing the exact location of every plate and rivet hole in the completed structure, are then taken apart, nested on flat cars and dispatched to the railroad station nearest the point of their destination on the Mojave Desert. From here they are freighted by twelve mule team wagons from 5 to a maximum of 30 miles to the point of erection where the diagrams have already preceded them. Here they are lifted by aerial trams to their place along the canon wall and are riveted into place. Twenty-four-inch double disk gate valves are placed at the lowest points of the siphons, first, for cleaning purposes, and secondly, to divert the flow of the aqueduct into natural water channels should a break occur in the conduit high along the mountainside to the south of them. This work is proceeding simultaneously at seven different points and should be completed during the second week in January.

Where the head is low, concrete siphons are used in place of steel on account of the cheaper cost. These pipes, used also in the approaches to the steel siphons, are 10 feet in diameter, strongly reinforced with steel and constructed of very rich cement. The illustration shows the manner of reinforcing.

For the partial development of the hydro-electric power, the city voted $3,500,000 in the spring of 1910. While the aqueduct is being built primarily for a domestic water supply this feature in point of revenue is by far the most important. The Board of Electrical Engineers reported in 1910 that a maximum of 99,000 kilowatts, or 120,000 horse-power, can be generated from the aqueduct with all conditions present for reliability of service and favorable low costs of operation. Owing to the regular and assured flow through the aqueduct, they reported that in their opinion no reserve steam plants are necessary and that from this and other favorable conditions, one of which is that the major part of the electric energy can be developed in close proximity to



One of the Hydraulic Dredges at Work Near the Intake of the Aqueduct.

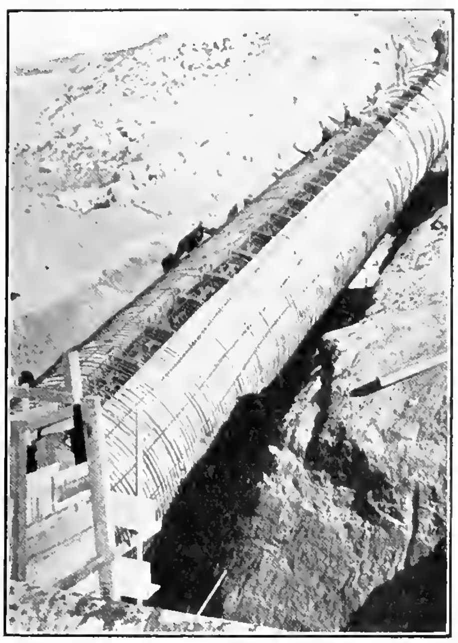
the city, the cost delivered at the Los Angeles city limits will not exceed $60 per horse-power. This is much less than the cost at which hydraulic power is at present developed on the Pacific Coast.

The plans call ultimately for the operation of seven power houses, two of which, Division Creek and Cottonwood, are now in service as construction plants.

These plants are as follows:

Name.	Maximum net head.	Kilowatts at switch board max. flow max. head.	Length of transmission line to Los Angeles.
Division Creek	1,210	600	225
Cottonwood, No. 1	1,218	1,500	185
Cottonwood, No. 2	2,065	2,500	190
Haiwee	182	4,590	162
San Francisquito, No. 1	905	51,750	47
San Francisquito, No. 2	512	32,000	40
San Fernando	281	7,225	21
Los Angeles sub-station		90,000	

(11 per cent. transmission loss, including step-up and step-down transforming)

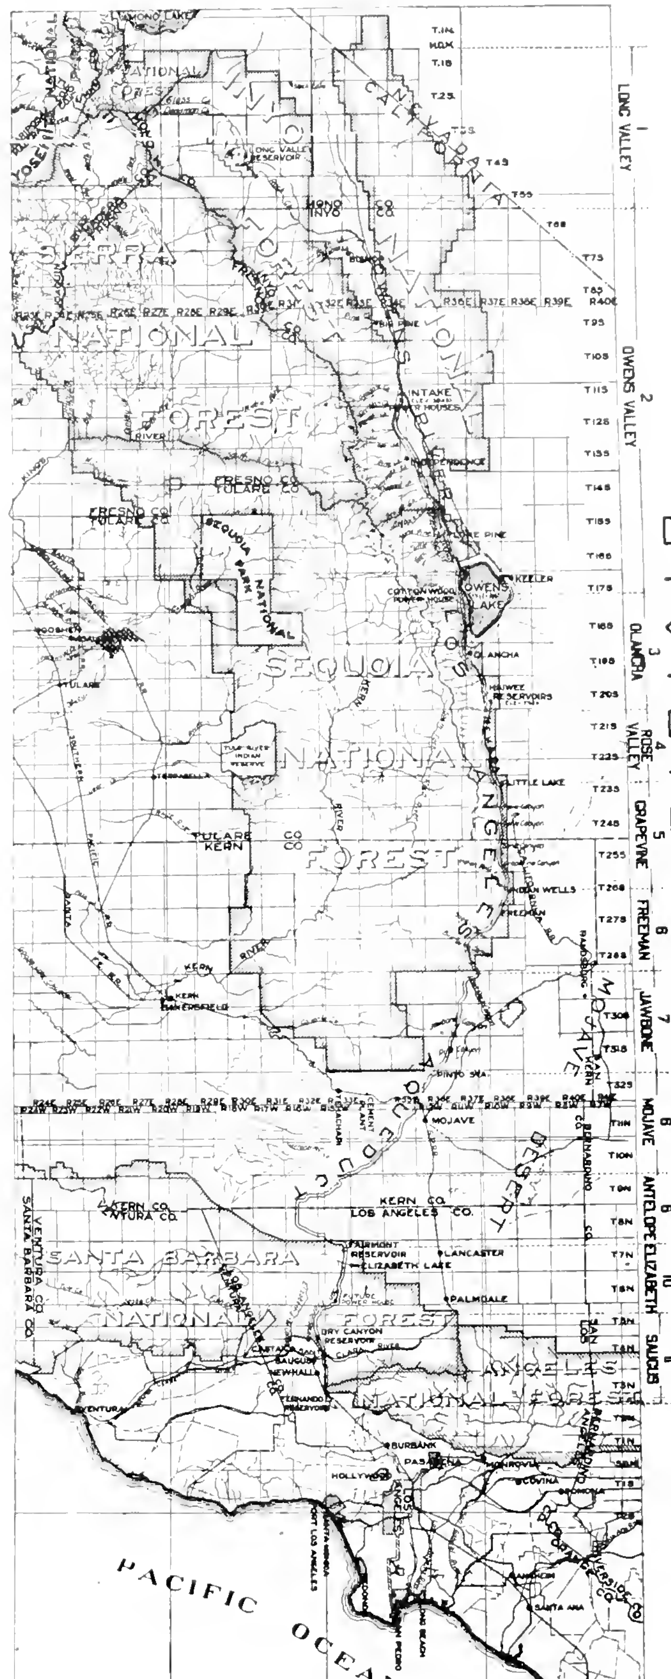


Constructing One of the Concrete Siphons.

Plans for the partial development of power house No. 1 in San Francisquito canon are now ready for the construction department. Contracts have been let to the Union Iron Works and the Westinghouse Company for machinery to cost $300,000 with delivery to be completed by January 1st, when the buildings will be ready to receive it. This plant will have a capacity of 37,500 horse-power and is scheduled to be complete and ready for operation in April of 1913. Other units of power will be installed as a market for the product develops.

Whether the power will be disposed of to the Los Angeles power companies at a wholesale rate or a $5,500,000 distribution system built by the municipality remains to be voted upon by the people, whose attitude at the present time is strongly in favor of the latter alternative.

Irrigation, the last subject to be discussed, is second only to power development from a financial standpoint. It must be kept firmly in mind that Los Angeles lies within a semi-arid region, where land values are directly proportionate to the accessibility of water for irrigation. This is shown by the fact that lands which will be watered by the aqueduct,



Map of the Los Angeles Aqueduct and Adjacent Territory.

as dry land sold from $20 to $50 per acre seven years ago and to-day are being sold from $350 to $500 per acre.

Approximately 225,000 acres of land for which little water is now available lie within a radius of 30 miles of the municipality. The surplus waters of the aqueduct will supply irrigation for 135,000 acres of this amount, allowing for the return of 2,000 miner's inches by seepage into the city's present infiltration galleries, provided the Fernando Valley is given irrigation.

Studies by the Los Angeles Water Department show that it requires the same amount of water to irrigate an acre of citrus trees that is required for an acre given up to urban population. The city, in its remarkable growth, is constantly encroaching on urban lands. The very nice problem enters of applying the water for irrigation in the localities which will gradually and insensibly grow from suburban into urban territory with the accompanying gradual transfer of the water from irrigation to domestic use.

For the past year a corps of engineers have been working on this problem. The irrigation system will therefore probably differ from the concrete canal systems found in California in that it will consist of large steel pressure mains ranging from 4 to 6 feet in diameter leading off from the Fernando reservoir to water the country below it. Probably the plan adopted by the United States Reclamation Service of forming irrigation districts will be put in force. In this event the districts will be required to defray the cost of all the work which will be installed by city engineers and become the property of the city. The actual cost to the irrigators has not been fixed, but the average annual rental for water in Southern California is approximately $10 per acre.

With all the available water power developed and with the surplus water disposed of for irrigation, Mr. J. B. Lippincott, assistant chief engineer of the aqueduct, has computed that for a total expenditure of $31,500,000 Los Angeles will receive a net annual income of $4,425,000, which is the equivalent of 5 per cent. interest on $88,500,000.

In conclusion, this project, now on the eve of completion, stands out clearly as the foremost municipal engineering achievement of history. It is an enterprise of which a nation might well be proud. In its large conception, its building by city forces, and its promise of large economic returns, this project certainly is one that is destined to have a very vital influence upon many other cities of America where the clamor for the ownership and operation of public utilities grows constantly louder.

OCTOBER RAILWAY TRAFFIC EXCEEDS ALL RECORDS.

The receipts and expenses of the steam railways for the month of October, 1912, are greater than for any other month in their history. Net operating revenue, which is the gross income before anything has been taken out for taxes and rentals, interest on bonds, appropriations for betterments or dividends, averaged $15.71 per mile of line per day, which contrasts with $13.74 for October, 1911, an increase of $1.97. This is an increase per mile of line for the month of $61.13, or 14.4 per cent.

The monthly summary of the Bureau of Railway Economics, compiled from the reports of railways to the Interstate Commerce Commission, covers for October 220,636 miles of line, or about 90 per cent. of all of the steam railway mileage of the United States. The aggregate net operating revenue for this mileage was $107,440,518, which is greater by $14,870,125 than that for October, 1911. The increases were due in greatest proportion to the freight traffic, which is always greater in October than in any other month of the year.

GOOD ROADS IN ALBERTA.*

By J. D. Robertson.†

The Local Improvement Organization, and works, done under this organization, have not, in all cases, been satisfactory. Many reasons have contributed to this, one being that the works facing such organizations were of such a character and magnitude that the funds at their disposal were not sufficient to cope with the situation. Another cause has been the fact that earth roads, when once built, in many parts of the Province require so much in the way of maintenance that little of value has been accomplished. The system of commuting taxes by labor has not, in my opinion, contributed much to the improvement of roads, but instead established a system which, while necessary in the new and sparsely settled districts, has frequently been continued after settlement was more dense, when vastly better work could have been accomplished by collecting the money and employing some capable man as foreman to conduct the work under the direction of the Council. The system of each Councillor having charge of the expenditure of all money in his particular division or township, regardless of main road requirements, without any comprehensive plan approved by the whole Council, has resulted in disconnected pieces of works here and there without much continuity of purpose.

Another matter might also be mentioned, which has not, in our opinion, contributed very largely to the improvement of roads, is the fact that the rate of assessment may be placed at anything from one and one-quarter cents to five cents per acre. We find certain districts, since their organization, assessing to the limit, while others, in which works are quite as necessary, assessing at the lowest figure, or very close to it. In other words, one man will pay $8, local improvement taxes, on one quarter section, while perhaps his neighbor, who is using the same roads, is paying only $2 per quarter section, which, to our mind, is certainly not just, and it is noted, in sections of the country where only the one and one-quarter cent per acre or $2 per quarter is levied, they are quite as persistent in their requests for Government assistance as where they are assessing themselves to the limit. Under such conditions the Local Improvement Organization could not be expected to receive the hearty co-operation of the Department that it deserves. It is to be hoped that some of these difficulties and drawbacks will be removed under the Municipal Organization, where such is put in force, and also under the re-organization of Local Improvements Districts, where municipalities are not formed. It should be mentioned here that, while certain districts have been handicapped by the difficulties mentioned above, others have taken the best out of the Act, under which they are working, and have achieved very satisfactory results. In conducting work for the Government, on the improvement of roads, we are well aware of the many difficulties to be contended with, and it is to be hoped, when another year's work is begun, that we may have an even more hearty co-operation with the new organizations than it has been possible to have under the old regime. In most of the Province the building of permanent highways is still in the distance, and, for this reason, I am going to confine my remarks to the more primitive works.

Grading Earth Roads.—The fact should always be borne in mind that water from melting snow or ice and rain is the principal factor against which we have always

* Address delivered before Alberta Local Improvement Districts Association, Edmonton, Alta., November 26th and 27th, 1912.

† Provincial Engineer of Highways of Alberta.

to contend in the construction and maintenance of earth roads, water on the surface causing clay or loam roads, even under light traffic, to work up into an impassable condition, and, during long continued wet weather or under heavy traffic, such roads will always be bad, though their unsatisfactory condition may be minimized greatly by first building them up to a rounding surface with grader, then maintaining their surface by frequently dragging to fill ruts, caused by wheel traffic, so the water will run off instead of lodging in them and soaking into the road, causing the mudholes so often encountered on earth roads. The split log drag, or several types of similar implements working on the same principle, have been found very effective and economical in maintaining such roads, costing about one-third as much as a blade grader to trim up rutted roads, and, in many cases, doing quite as efficient work. In many parts of the Province the heavy clay loam, so desirable for agricultural purposes, is a most unsatisfactory road material, will not carry heavy traffic when dry, and absorbs water freely in wet weather, with the result that such roads go to pieces. In some parts of the Province gravel is available for top dressing, and, when within a reasonable distance, makes a great improvement for a time, but soon works down into the clay, when the process must be repeated. A top dressing of sand has been experimented with on heavy clay roads and found to give very satisfactory results, but this, like the gravel, soon becomes mixed with the clay, when another coat of the same material is required. Frequently neither gravel or sand are obtainable within a reasonable distance, and are sandy or gritty subsoil, frequently found and exposed by the ditches along roads, generally upon hills or slight elevations, provides a top dressing far superior to the natural clay loam, some of it packing and binding very satisfactorily under wheel traffic, and forming a roadbed quite impervious to water, and since macadam and the many types of asphalt are probably, owing to their cost at the present time, out of our reach, a great improvement might be made on country roads by making the best use of material available.

Draining to Prevent Seepage of Water from Side Ditches Into the Roads.—This, in many places, is of more importance than raising the road by grading, and frequently costs less. It will be noticed, where pools of water are allowed to lie in the ditch alongside of roads, that the road frequently breaks down into impassable mud holes. This is caused by the seepage of water into or through the road bed. In many cases such water can easily be drained along the side of road, or away from it, at a less cost than fixing the mud holes by raising the road after the water has caused the damage. Grading the bottoms of ditches, so water will drain off, is quite as important as grading the surface of road, but, considering that it is a common practice all over the Province to pasture cattle on the road allowance, where the ground is soft and ditches necessary, they are soon tramped in, damming up water and undoing the work that has cost large sums of money. If the owners of cattle, grazing on the roads, were compelled to repair the damage done by them, in wet country where drainage is necessary, the revenue for road improvements might be considerably increased. Considerable damage is also done tramping down the approaches to bridges and culverts, and I never knew of it occurring to the owner of a large or small herd of cattle, that anyone but the public should contribute to the improvements made necessary by his grazing them on the roads. Of course, in certain parts of the country, where there is vacant or unfenced land, it is difficult or impossible to prevent such damage, though in other parts, where well fenced, the highway is considered a convenient public pasture. Proper ditching, on hills or hillsides to carry off the water and prevent it running down the wheel tracks and destroying the road in many parts of the country, receives but scant attention. I have observed many hills, where a road had been well constructed and properly ditched, where immense damage had been done by water running down upon it, when a few dollars spent keeping the drains open would have avoided considerable loss and inconvenience caused by an impassable road, and in this respect I would ask for the hearty cooperation of the Local Improvement District to keep such ditches open. Before closing my remarks on primitive earth roads, I would like to say a few words with reference to the use of brush, where such is available, for a corduroy or bottom on wet or springy ground. It frequently happened, where such is required, that nature has provided brush in the immediate locality, the very nature of the soil causing a growth of willow, and, where such exists, and frequently has to be cleared from the road, it is a good practice to use it for a brush mat in wet places, covering this again with the best material available, when a foundation will be provided for a road that should be passable even in bad weather, while, without brush or corduroy, raising a grade with the material available frequently results in simply adding to the depth of mud to be travelled through. In certain parts of the Province, where the country is wet and drainage not feasible, too much attention cannot be attached to this precaution. Another practice sometimes followed is to grade roads through low wet ground, sloughs and potholes, during dry weather, without much provision to drain the water off, when it turns wet, or, at least, to control it so it will not rise over the road. Large amounts of money have been spent grading such roads in this Province, that were lost when the weather turned wet and the sloughs and potholes filled up with water. When it is not feasible to put in drainage, to at least control the raise of water, and the high water mark is in evidence, and money is not available to raise the grade above such high water mark, then the obstruction should be gone around, otherwise the money put into it is pretty certain, sooner or later, to be lost. There is a very general impression, in the minds of the public, that statutory road allowances, as laid out under our system of sub-division, should be followed regardless of physical difficulties, which is entirely erroneous, and results in an attempt being made to grade down impassable hills, and to grade roads over ground quite unsuitable for road purposes, that might and should be gone around. In the older Provinces the system of survey differed from ours, and the Crown reserved a certain percentage from all lands for such purposes. Our old trails, in many localities, illustrate what we might have had, in the way of roads, where the contour of the country is more generally followed. While on level prairie it is generally quite feasible to follow road allowances, the same system is quite unsatisfactory in rough or broken country, and a very sincere effort should be made to overcome the objections of the owners of lands, where such diversions are necessary so a permanent and safe road may be established.

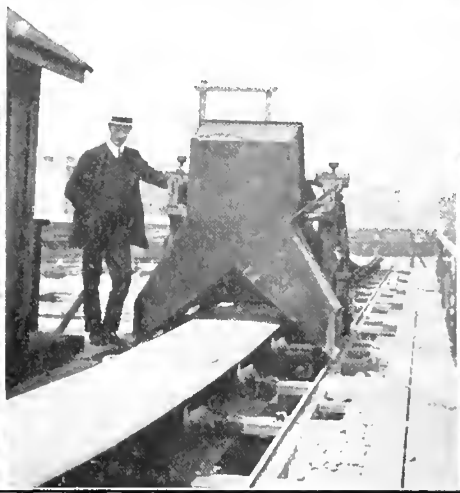
QUEBEC STREAMS COMMISSION.

The Honorable S. N. Parent, chairman of the Quebec Water Works Commission, which has recently had its name changed to the Quebec Streams Commission and has been invested with the powers of a corporation in order to carry out its scheme of constructing a large storage reservoir on the upper St. Maurice, for the purpose of regulating the flow of that river for generating electricity, is in Quebec in connection with this work. The area of the proposed reservoir will be more than 300 square miles and the amount of water to be stored will be about 160 billion cubic feet. It will drain a basin of more than sixteen thousand square miles in area, and give a regular flow of 18,000 cubic feet per second in Shawinigan and other places.

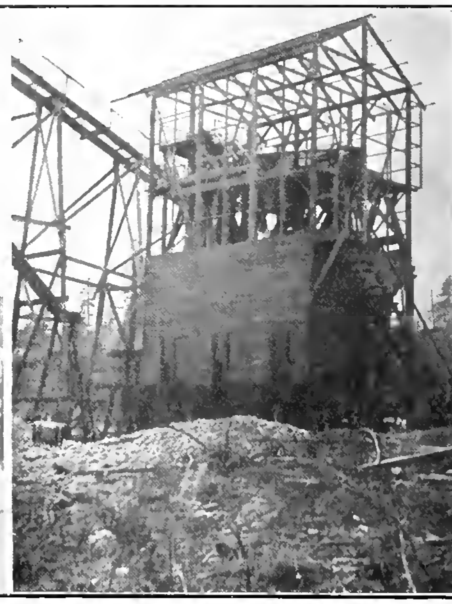
A GRAVEL SCREENING AND WASHING PLANT.

A gravel screening and washing plant built about a year and a half ago for the J. A. Dewar Company, Limited, in Vancouver, is of considerable interest from the standpoint of economical layout. The pits are located near Coquitlam, seventeen miles east of Vancouver, and the distributing plant is on False Creek in the city of Vancouver.

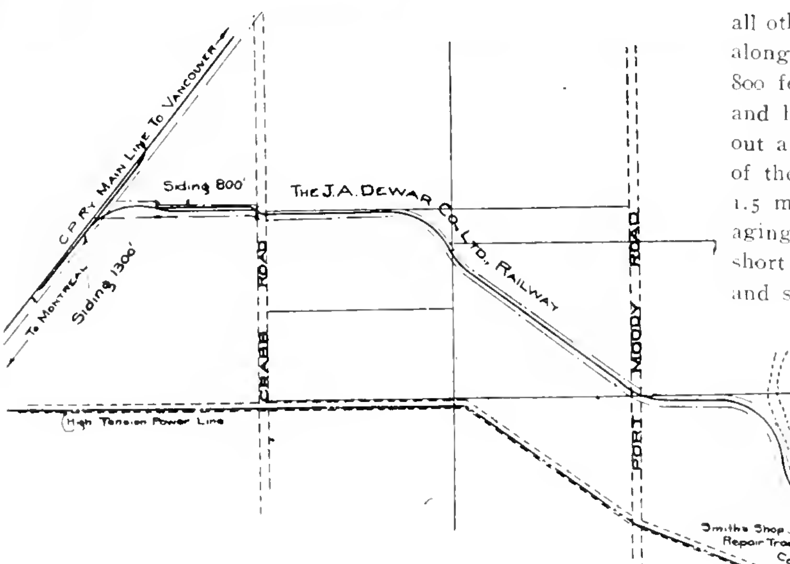
Rock Bin, Westminster Junction, B.C.



Tripper for Distribution to Bins.



Cravel Bin, Westminster Junction, B.C.



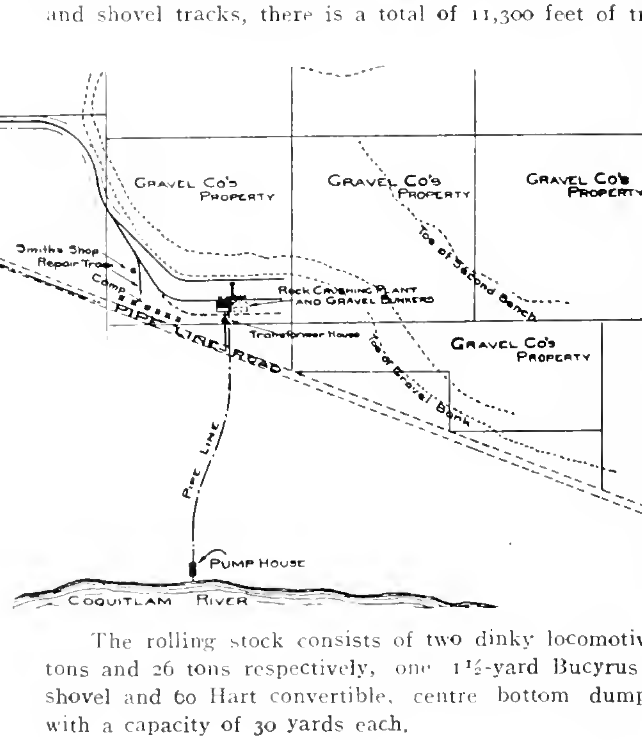


Fig. 1.—Plan of Railroad, Gravel Pit, and Pipe Line of the Gravel Screening and Washing Plant, J. A. Dewar Company, Coquitlam.

In the design and arrangement, the local demands received special consideration and although many gravel dealers brought the pit run to the machines at the city bunkers to be treated, it was decided that the place to treat the gravel was at the pit The correctness of this decision has since proved itself

The pit contains some 20 per cent. of stone too large for classification as gravel. It was therefore necessary to devise some means of disposing of it at slight cost or to put in an auxiliary rock crushing plant, and as of late the demand for crushed stone has been in advance of the supply it was decided to crush the big stones.

Fig. 1 shows a plan of the railroad, gravel pit and pipe line from the river. Fig. 2 shows on a larger scale the general arrangement of the washing and crushing plants and their relation to the pit and dumping hopper, also the system of extension. Fig. 3 shows the plant in the city.

The railway gives shipping facilities to Vancouver and all other points. The spur to the pit is connected to a siding along the main railway line of 1,300 feet, also to a siding of 800 feet along the gravel company's line, so that empties and loaded cars may be easily changed and switched without any interference with the railway company. The length of the gravel company's line from the railway to the pit is 1.5 miles and is on their own right-of-way. the grade averaging 1.7 per cent., the maximum being 2 per cent. for a short distance at one place. With the loading, repairing and shovel tracks, there is a total of 11,300 feet of track.

The rolling stock consists of two dinky locomotives, 13 tons and 26 tons respectively, one 1½-yard Bucyrus steam shovel and 60 Hart convertible, centre bottom dump cars with a capacity of 30 yards each.

Owing to the difficulty of obtaining right-of-way on certain property, the line is somewhat sinuous but it is practically a surface line and was constructed cheaply.

The pit consists of a bank some 40 feet high above the

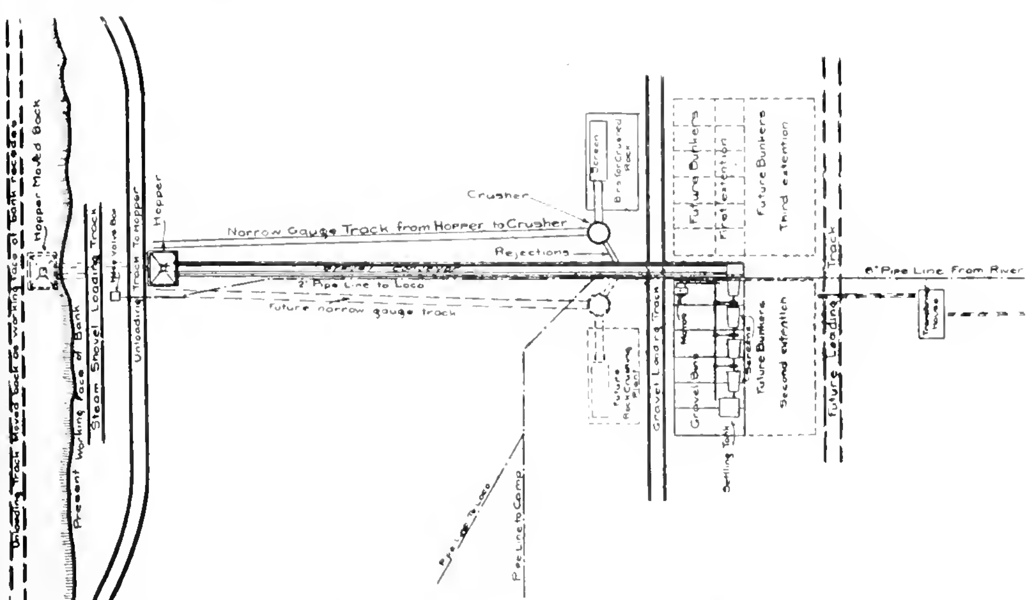

Fig. 2.—General Arrangement of the Gravel Washing and Screening Plant.

general level which gives an ideal steam shovel working face, the deposit extending over some 160 acres.

The method of operation is obvious from the layout. The steam shovel loads a 6-yard side dump car which is

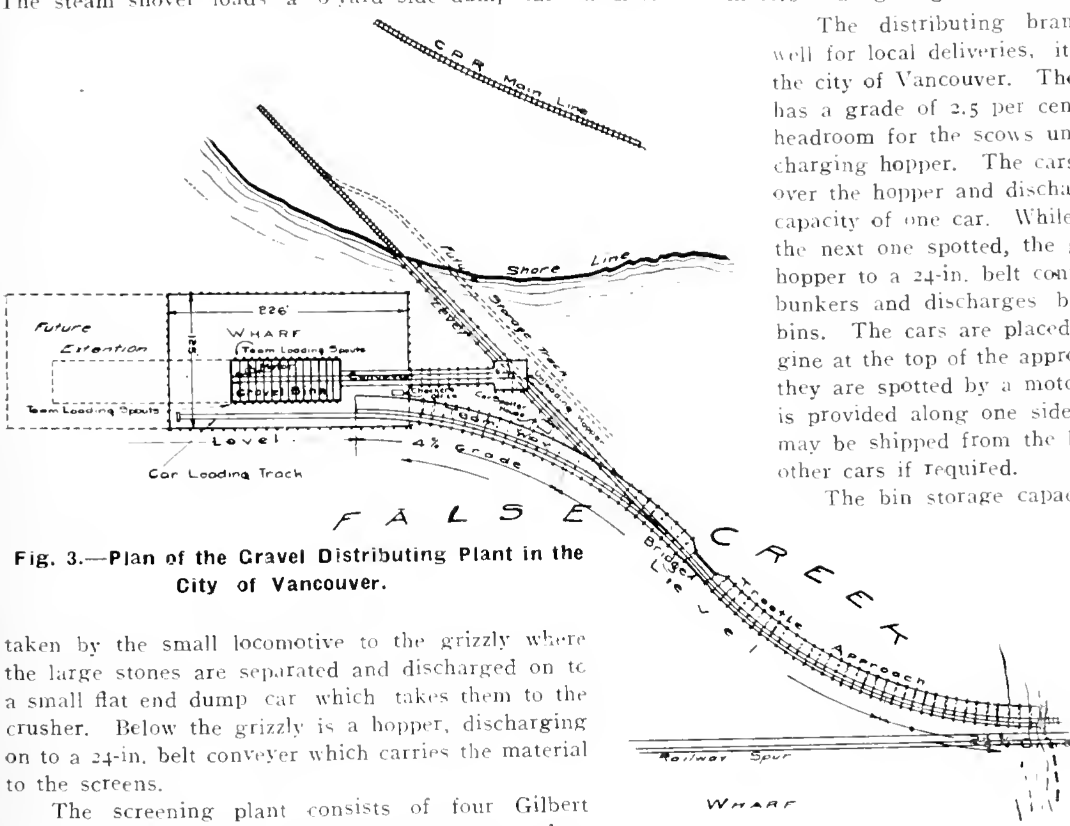

Fig. 3.—Plan of the Gravel Distributing Plant in the City of Vancouver.

taken by the small locomotive to the grizzly where the large stones are separated and discharged on to a small flat end dump car which takes them to the crusher. Below the grizzly is a hopper, discharging on to a 24-in. belt conveyer which carries the material to the screens.

The screening plant consists of four Gilbert screens, 36 in. x 54 in. x 6 ft. 0 in. (driven by a 15 h.p. motor), giving four separations 2 in., 1 in., ½ in., and sand. The sand passes through a gravity setting tank to remove the water. The rejections from the first screen pass by chute to the crusher. After being crushed they are elevated by a chain bucket elevator to the revolving rock screen which separates into three sizes, the rejections being passed back to the crusher for re-crushing.

The bunkers are arranged to discharge into the cars on the loading track alongside, the cars being pushed in by the larger loop.

As will be seen from the plan, extensions may be made to any desired capacity and the machinery duplicated without alteration or interference with the present layout. The capacity is 500 yards of gravel and 200 yards of crushed rock per 10-hour day. On the plan is shown the order of extension up to 2,000 yards of gravel and 400 yards of crushed rock.

The water used by the plant for the boilers, camp, etc., is supplied by a three stage, 4-in. centrifugal pump, located in the pump house at the Coquitlam River, a distance of 3,300 feet, and is driven by a 35-h.p. motor. The wiring is arranged so that the motor must be started from the pump-house, but may be shut down from the camp if necessary. The pipe line is a 6-in. wood pipe. Power is supplied by the B.C.E. Railway Company, at 2,200 volts, to the transformer house, where it is stepped down and fed through the switchboard to the several motors and lighting circuit at 220 volts.

The distributing branch is located exceptionally well for local deliveries, it being right in the heart of the city of Vancouver. The trestle, as shown in Fig. 3, has a grade of 2.5 per cent. on the approach to obtain headroom for the scows underneath bridge and for discharging hopper. The cars of graded gravel are placed over the hopper and discharged, the hopper having the capacity of one car. While the car is being moved and the next one spotted, the gravel has passed out of the hopper to a 24-in. belt conveyer which conveys it to the bunkers and discharges by tripper into the respective bins. The cars are placed by the C.P.R. switching engine at the top of the approach trestle, from which point they are spotted by a motor-driven car haul. Trackage is provided along one side of the bins so that gravel may be shipped from the bunkers by street railway or other cars if required.

The bin storage capacity is 1,200 yards and is arranged for team delivery. Here, again, the capacity may be increased without much alteration to the present layout, the only change being an extension to the belt conveyer and moving the conveyer head drive as bunkers extend.

Although in two branches the plant easily competes with the scow delivery usual in Vancouver, it being greatly favored by the non-liability of being held up by fogs or storms. An interesting feature at both branches of the plant is the crib type of construction for the bins, which, though not reducing the B.M. of lumber in the structure, yet allows a cheaper class of labor to be employed and requires less time for construction.

This gravel plant has been in operation 1½ years and is giving every satisfaction, both commercially and mechanically. Eighteen men are employed, including superintendent, at the pit, and two men, including checker, for the teaming at the city branch. The unloading at the city end is stated to be the most efficient and economical in Vancouver.

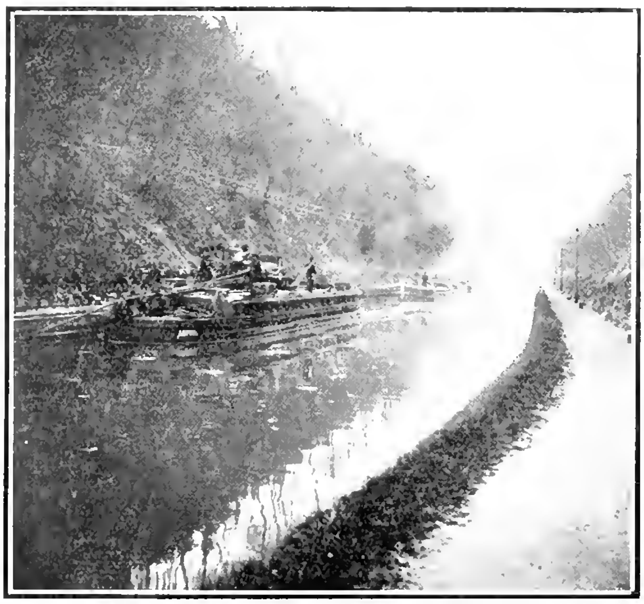
The gravel company own their own rolling stock as mentioned, also telephone system and camp. They erected the Westminster Junction plant by day labor but built the Vancouver branch by contract.

The owners are The J. A. Dewar Company, Limited, of 429 Pender Street, Vancouver. Mr. S. A. Lake, of Wilson & Lake, consulting engineers, 422 Pacific Building, Vancouver, designed and superintended the erection of the plant.

ELECTRIC PROPULSION OF FREIGHT BOATS.

It has been stated in the press that a navigation company of Montreal is considering the propulsion of boats on the Lakes. One electric motor boat, it is said, was already designed and will be operated on the same principle as an electric car.

This mode of propulsion is already used in France, and boats have been fitted out for such purpose by the "Société



View of Canal of St. Quentin, Showing Freight Boat with Electrical Propulsion.

Alsacienne"; this company is represented here by the "Engineering Works of Canada," of Montreal.

The reproduced photograph shows such an electric motor boat hauling five loaded freight boats through the canal of St. Quentin.

There was also another system tried which consisted in a motor car running along the canal and hauling the boats by means of ropes. The car was equipped with electric motors which received their power from a trolley; however, it has been found much more advantageous from every point of view to use a special boat equipped with electric motors which are mounted on the propeller shaft; the motive power is supplied from a trolley line.

This system is, of course, not applicable in the present case, but in special instances, like for ferry boats, etc., it could be used with advantage.

WHAT HYPOCHLORITE ACCOMPLISHES.

In a paper delivered before the International Congress of Applied Chemistry, held in New York City in September, 1912, Mr. C. A. Jennings gives some information regarding the true place of hypochlorite in the treatment of water. An abstract of the paper follows:—

In considering typhoid fever statistics before and after the introduction of the hypochlorite treatment, it is often very difficult to make a fair comparison, for the reason that there is a woeful laxity in reporting these statistics in many cities. This is usually conscientiously looked after following an epidemic, but seldom previous to one. However, the writer has gathered sufficient reliable bacteriological data, as well as typhoid fever statistics, to show the effect that sterilization has had on the bacterial content of the water and on the reduction in the number of cases and deaths from typhoid fever.

Bacteriological Data.

Terre Haute, Ind., has a pressure-filter plant. The average bacterial count for February, March and April, 1912, was: Raw water, 3,870 per c.c., with B. coli present in 68 per cent. of the samples tested, while the filtered and sterilized water showed only 34 per c.c., with B. coli absent in every sample tested. Samples were collected daily.

Cedar Rapids, Iowa, began using hypochlorite in March, 1912, as an adjunct to its rapid sand filters, and the results have been spectacular. During the period from March 29 to May 15, 1912, the raw water averaged 40,200 bacteria per c.c.; filtration alone showed a reduction in bacteria of 1,700 per c.c., or 95.8 per cent., while the hypochlorite treated water count was only 44 per c.c., or a total reduction of 99.9 per cent. B. coli was present in 63 per cent. of the raw water samples examined, in 36% of the filtered water samples, but not a single 1 c.c. portion of the sterilized water showed B. coli.

Montreal, Que., draws its water supply from the St. Lawrence River, and sterilizes it with hypochlorite. The untreated water averages 800 bacteria per c.c., with B. coli present in 98 per cent. of the 10-c.c. portions, and in 45 per cent. of the 1-c.c. portions tested. The treated water averages 25 bacteria per c.c., with B. coli absent in both 10-c.c. and 1-c.c. portions tested.

Grant's Pass, Ore., has, as its source of supply, Rogue River, a clear mountain stream. However, there are several sources of pollution by sewage from cities above. The hypochlorite treatment reduces the bacteria from an average of 600 to 15 per c.c. Since the hypochlorite process was begun September 16, 1911, and up to June 1, 1912, there were but two cases and no deaths from typhoid fever reported in this city of 5,000 inhabitants.

Baudette, Minn., had a typhoid fever epidemic in the fall of 1910, and began immediately to sterilize the water supply. No specific data are available, but the following quotation from a letter from the town clerk is significant: "It has been our experience that the hypochlorite plant is a very valuable asset. Previous to installing the hypochlorite plant typhoid fever was very common. Since that time (to May 30, 1912) no typhoid fever has been called to our attention. We, therefore, believe that the hypochlorite plant has been a very satisfactory preventive of this class of disease."

Nashville, Tenn., after drawing the water from the Cumberland River, coagulates it with alum and allows it to settle in large basins. It is then sterilized with hypochlorite of lime. The average bacterial content of the raw water is 3,000 per c.c., with 90 per cent. of the 1-c.c. portions tested showing B. coli present. The settled and sterilized water shows an average of only 70 bacteria per c.c., and during the year 1910 only three samples out of 1,200 tested showed B. coli present.

Danville, Ill.—Although Danville has been using the hypochlorite treatment as an adjunct to its rapid sand-filter plant for only a very short time (since February, 1912), nevertheless the bacterial data on the filtered water are very interesting. During the time that hypochlorite was used the average bacterial content of the sterilized filtered water was only 57 per c.c. During the period from March 20-25, inclusive, the supply of hypochlorite was exhausted and so none was used. The bacterial content of the untreated filtered water during this period was 4100 per c.c. With hypochlorite treatment in use Mar. 19, the count was but 20 per c.c.; on Mar. 20, without hypochlorite, the count jumped up to 8400 per c.c. The removal by filtration without hypochlorite, from the raw water averaging 67,000 bacteria per c.c., was 93.9%; by filtration and hypochlorite from the raw water averaging 52,406 bacteria per c.c., the removal was 99.89%. Without sterilization, B. coli was present in the filtered water on five of the six days; with sterilization, B. coli was present on one day out of 34. The turbidity of the raw water was so low from May 26 to June 1, 1912, that no coagulant was used and only hypochlorite added to the filtered water. The average reduction in bacteria during this period was 99.6%.

Typhoid Statistics.—A comparison of typhoid-fever statistics before and after the introduction of hypochlorite is very interesting.

North Yakima, Wash.—In 1910 there was a typhoid epidemic caused by a contamination of the domestic supply through a cross-connection with a highly-polluted fire service. During the period September, 1911, to June, 1912, there was not a single death from typhoid fever and only one case was reported between Dec. 22, 1911, and June, 1, 1912. The water sterilization began July 9, 1911. The source of supply is a mountain stream which is open to contamination. The reduction in the number of cases and deaths from typhoid fever is due in part to the general clean-up and condemnation of many polluted shallow wells as well as to the hypochlorite treatment in this booming city of the Northwest.

Council Bluffs, Iowa.—The wonderful efficiency of hypochlorite is shown by a typhoid-fever epidemic in Council Bluffs, Iowa, which began in the fall of 1909 and ended with the introduction of hypochlorite in April, 1910. Since this treatment was inaugurated, a period of 25 months to June 1, 1912, there have been but five deaths from typhoid fever in this city with a population of 30,000 and one of these five deaths was that of an imported case. This is a remarkable record. For the eight months following the introduction of hypochlorite there was not a single death from typhoid fever.

Cleveland, Ohio., draws its water-supply from Lake Erie, which is polluted in part by its own sewage and in part by neighboring cities. After typhoid fever had been prevalent to a great degree in this city for years a remarkable reduction in the number of cases and deaths from this disease followed the beginning of the treatment with hypochlorite in September, 1911. There was 159 cases and 19 deaths reported for that month. For the eight months, Oct. 1, 1911, to June 1, 1912, there were totals of 180 cases and 28 deaths reported. During similar periods in previous years the figures are:

	Cases.	Deaths
Oct. 1, 1907 to June 1, 1908	290	46
Oct. 1, 1908 to June 1, 1909	311	52
Oct. 1, 1909 to June 1, 1910	343	66
Oct. 1, 1910 to June 1, 1911	347	65
Average 1907-1911	323	57

These figures compared with 180 and 28 cases and deaths, respectively, for 1911 to 1912 show reductions of 44% in the number of cases and 50.8% in the number of deaths. This represents an average of 29 fewer deaths in eight months, while hypochlorite was being used compared with the period before the water was treated. Taking the figure of $5,000 as the value of each life sacrificed to typhoid fever, the financial saving effected by hypochlorite in eight months has been $145,000, which amount capitalized at 5% represents the tremendous sum of $2,900,000.

Erie, Penn.—Although it is acknowledged that the typhoid epidemic at Erie was water borne, nevertheless the exact point of introduction of the contamination has not been definitely determined. The water-supply is taken from Lake Erie and, previous to Mar. 15, 1911, was not treated with hypochlorite. December, 1910, with 31 cases and 2 deaths was followed by January, 1911, with 239 cases and 24 deaths. The Pennsylvania State Board of Health began treating the water-supply with copper sulphate Jan. 28, 1911, and this was continued until the hypochlorite was substituted. The latter process has been in use without cessation since Mar. 15, 1911. The number of cases and deaths from typhoid fever during the twelve months from June 1 to May 31, during the past four years, is as follows:

	Cases.	Deaths.
1908-1909	153	16
1909-1910	202	29
1910-1911	1140	136
1911-1912	91	11

Thus it will be seen what a good record the hypochlorite treatment has made at Erie in the reduction of typhoid fever. The average number of cases and deaths for the three years 1908-1911 was 498 and 60 compared with 91 cases and 11 deaths since hypochlorite has been used. The value of 49 lives saved from typhoid fever at $5,000 each is $245,000, which, capitalized at 5%, amounts to a total of $4,900,000. The raw water averaged 674 bacteria per c.c., with B. coli present in 11% of the samples tested, while the treated water averaged only 49 bacteria per c.c., with B. coli present in only 1 sample out of 1,025 examined—less than 0.1%.

Toronto, Ont.—During the first two months of 1910 there were 723% more cases and 450% more deaths from typhoid than the average for the same two months during the five years previous. Hypochlorite treatment was begun in March, 1910, and an immediate reduction in the number of cases and deaths was effected. The cause for a rise of cases to 90 for two consecutive months in 1911 is explained in a quotation from a letter from Dr. Geo. C. Nasmith, Director of Municipal Laboratories:

I may say that last year our intake plugged with sand and we were forced to short circuit our water-supply and take it from the Bay into which all our sewage empties. We had the makings of the largest typhoid epidemic ever known on this continent, but fortunately we had hypochlorite to depend on and we came through with a typhoid death rate of 20 per 100,000 in 1911, as compared with 45 per 100,000 in 1910, which, you will agree, was an extremely satisfactory showing.

The first four months of 1912 show 64% fewer cases reported than the same period in 1911 and 65% fewer cases than the average for the same periods 1905 to 1910 inclusive and 50% fewer deaths.

Baltimore, Md., drawing its water-supply from two impounding reservoirs, began to sterilize the water with hypochlorite on June 6, 1911, to keep down the annual autumn typhoid-fever epidemic. Since then both cases and deaths have been lower than before the use of hypochlorite. For the period June 1, 1910, to May 31, 1911, there were 1,964 cases and 233 deaths from typhoid fever, while from June 1,

1911, to May 31, 1912, while using hypochlorite, there were 1,155 cases and 160 deaths, reductions of 41% and 31%, respectively. Hypochlorite treatment presumably saved 73 lives in one year. These valued at $5,000 each, amount to $365,000, which totals the enormous sum of $7,300,000 when capitalized at 5%. This is a wonderful saving to a community of 564,000 people in twelve months.

Evanston, Ill.—During the past winter Evanston, Ill., had a typhoid epidemic, traceable to the water-supply, contaminated by the sewage of the city itself. Although the use of hypochlorite was not begun until December 10, 1911, nevertheless there was a reduction from 40 cases reported in December, 1911, to 12 cases in January, 1912, which dropped still further to nine cases in February, showing how thoroughly the hypochlorite treatment did its work. The untreated lake water, averaging 5,000 bacteria per c.c., with B. coli present, was reduced to an average of 75 per c.c., with B. coli shown to be present in all 1-c.c. portions tested.

Waukegan, Ill.—Conditions as to the pollution of the water-supply of this city with the city's own sewage are identical with those of Evanston. The increase in typhoid-fever cases reported, however, occurred later than in Evanston. A total of 82 cases in March was reduced to 50 in April and 27 in May, hypochlorite having been used for the first time on April 16, 1912.

Minneapolis, Minn.—There was an abnormal amount of typhoid fever in 1909 and 1910. The water-supply was taken from the Mississippi River without any treatment. The use of hypochlorite was begun late in 1910 and has been continued without interruption since that time. A modern filter plant of the rapid sand type is now being constructed, but the hypochlorite process will be used in conjunction with it when completed. The water is reduced from an average of 816 bacteria per c.c. to 5 per c.c. The 39 typhoid deaths in the ten months before hypochlorite and the two deaths in the ten months after hypochlorite was used, or a reduction of 95%, is remarkable.

Omaha, Neb.—Hypochlorite has been used since May, 1910, at which time there was an epidemic of typhoid in the city. The Omaha typhoid fever death rates per 100,000 for the last four years have been:

1908	1909	1910	1911
16	26	67	13

A reduction from 67 to 13 per 100,000 is remarkable and it is difficult to say how much higher the rate would have been in 1910 had not the sterilizing process been installed in May of that year. It is worthy of mention that the treated and settled water shows an average of only 43 bacteria per c.c., whereas the raw water from the Missouri River averages 30,447 per c.c.

Jersey City, N.J., was one of the first cities to adopt hypochlorite treatment for municipal water-supplies. The water from the storage reservoir averages 12,000 bacteria per c.c., with B. coli present, but the treated water averages only 10 per c.c., with B. coli absent. Hypochlorite treatment was begun in September, 1908. The average for 1905, 1906 and 1907 was 18.5 per 100,000, and this was reduced to an average of 9.6 per 100,000 for the three years following the use of hypochlorite, namely, 1909, 1910 and 1911, a reduction of 48% in the average typhoid fever death rate.

Kansas City, Mo., takes its water-supply from the muddy and polluted Missouri River and by means of sedimentation and sterilization reduces the bacterial content from an average of 5,500 per c.c. to 65 per c.c. The raw water shows B coli present in 0.2 c.c., whereas this sewage organism is absent in all 1-c.c. portions of the treated water tested. The number of typhoid deaths reported during 1910 without sterilization of the water was 107, while for 1911, with hypochlorite treatment in use, it was 61, a reduction of 43%. Many people in Kansas City use the clear and sparkling waters that issue in many places from springs and which can be pumped from surface wells. These waters have been shown to be very highly contaminated, although they are of very attractive appearance. The city is now conducting a campaign to discontinue the use of these waters for drinking.

Cincinnati, Ohio., has a rapid sand-filter plant with a capacity of 112,000,000 gal. per day. The hypochlorite treatment has been used as an adjunct to the filtration process since December, 1910, with a reduction from an average of 315 to 26 per c.c., or 91.7% reduction in the filtered water itself. B. coli was present in 0.6% of the 1-c.c. samples and in 91.1% of the 100-c.c. samples of filtered water examined, but in the treated filtered water tested no 1-c.c. portions showed B. coli present and only 12% of the 100-c.c. portions were positive.

These data show conclusively that the hypochlorite of lime treatment of water-supplies is wonderfully effective; that it reduces the bacterial content of water to a very low number; that it practically eliminates B. coli and, therefore, we think, B. typhosus, from water-supplies; that it is a very valuable adjunct to filter plants; that mountain streams and impounded reservoir supplies are made safe by its use; that it has stopped many typhoid-fever epidemics already begun and in all probability it has prevented many epidemics from occurring. Hypochlorite is not a panacea for all troubles arising from water-supplies, but when properly applied to the proper water in the correct quantities, it will accomplish wonderful results. Its great cheapness as to installation and operation, the short time necessary to install the treatment and its comparative simplicity, will surely cause disinfection by hypochlorite of lime to be continued and to be adopted by other cities where the supply is not all that it should be.

NEW HARBOR COMMISSIONERS.

Messrs. W. G. Ross, F. Robertson and Lieutenant-Colonel A. E. Labelle are the new harbor commissioners for Montreal.

Mr. Ross is a prominent business man and is a Montrealer by birth. His business career has been a bright one, and as managing director of the Montreal Street Railway from 1905 to 1911, he did much to make that one of the strongest of Canadian corporations. At the present, Mr. Ross holds the following offices: President of the Asbestos Corporation of Canada, director in the Dominion Steel Corporation, in the Quebec Railway, Montreal Light, Heat and Power Company; also many other official connections with noted Canadian corporations.

Mr. Farquhar Robertson, coal merchant, hails from Glengarry county, Ontario, having devoted several years of his life to farming in that district. His first step into commercialism was made when he became manager of a Montreal lumber concern. He started his coal business in 1879. Mr. Robertson is a director of the Montreal Transportation Company, the Prudential Trust Company, and was president of the Montreal Board of Trade in 1909, having been vice-president the year before. He is prominently identified with charitable undertakings, and was three times elected by acclamation to represent St. Andrew's ward in the city council.

Lieutenant-Colonel Alfred E. Labelle was born in Montreal, and has been for more than a quarter of a century one of Canada's most prominent grain merchants. In company with Sir Rodolphe Forget, George A. Grier and Thomas Williamson, he organized the St. Lawrence Flour Mills Company, of which he was chosen managing director. He is the president of the Chambre de Commerce and is prominently identified with the Canadian militia.

THE IMPROVEMENT OF VANCOUVER HARBOR.

In an article published in a recent issue of the British Columbia Magazine, Mr. R. H. Parkinson outlines certain improvements for the improvement of Vancouver Harbor by a suggested sea wall across the Second Narrows. As the matter is of considerable interest on account of the rapid approach of the completion of the Panama Canal we herewith present the discussion.

Canada's western portal "the lion's gate" gives entry to Vancouver Harbor, a salt water basin bounded on the west and east respectively by the First and Second Narrows of Burrard Inlet. This arm of the sea continues some sixteen miles inland in an easterly and northerly direction beyond the Second Narrows.

The whole area of Burrard Inlet is approximately 14,000 acres, while the area of Vancouver Harbor, lying between the First and Second Narrows, is about 3,200 acres.

The purpose of this paper is to point out some of the defects of this harbor, and to suggest a means of eliminating them, and of so improving the conditions as to make Vancouver one of the finest seaports in the world.

The shore line or possible length of wharf (parallel thereto) in this harbor exceeds eleven miles; but, owing to existing conditions, only a small proportion of shore line is used for wharves.

The existing wharves are built on piles, which are very short-lived, owing to the action of the teredo navalis, which honeycombs them and makes re-piling a constant necessity and expense.

The greatest disadvantage of the harbor is, however, its difficulty of entry through the First Narrows. This channel, which has a width of 780 feet, and a depth in mid-channel of 12 fathoms, has a cross-sectional area of 30,500 square feet, through which, at spring tides, the water rushes at the rate of six to eight knots an hour, causing back eddies and whirlpools, which are very dangerous to small crafts and even to large steamers during the period of foggy weather which prevails in winter. The tidal conditions are, indeed, so adverse as to cause serious menace and delay to shipping, and the accidents, collisions and wrecks that have occurred in these Narrows must be attributed to the high velocity of the tides and the cross currents caused thereby.

This high speed of the tide is also found in a lesser degree along the north shore of the harbor, where the city of North Vancouver is situated, and detracts from its value as a location for wharves at a point where the need of them is becoming more and more apparent.

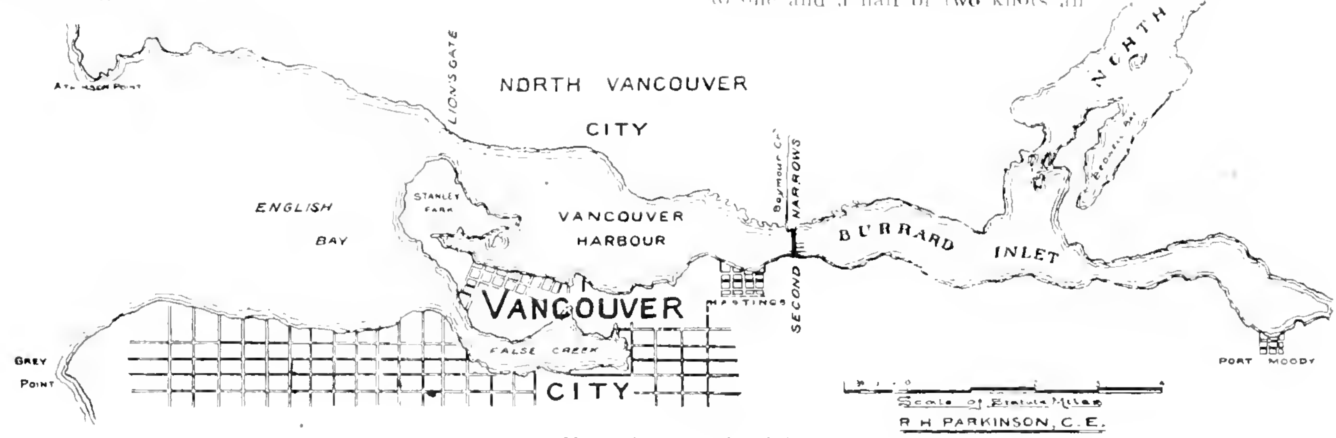
Another disadvantage at present existing is the lack of anything but steamer communication between Vancouver and her sister city across the harbor.

The difference of level between high and low tides is about fifteen feet, and this is a serious inconvenience, causing increased expense in the loading and unloading of ships. In older countries dependent largely on their sea traffic, vast systems of wet docks have been constructed to overcome the disadvantage of excessive tidal rise. The Thames has a tidal rise of 20 feet, and to contend with this London has built over 400 acres of wet docks.

Liverpool, with a tidal rise of from 20 to 30 feet, has the finest dock system in the world, consisting of over 600 acres of wet basins, with over 40 miles, of dock space. Part of these docks have cost as high as $244,000 an acre. It is therefore evident that a large tidal rise is considered such a detriment to a port as to warrant the expenditure of enormous sums of money in improving the harbor facilities.

The remedy for the evils mentioned, in the belief of the writer, lies in the erection of a sea-wall across the Second Narrows, which might take the form shown in the annexed plan and elevation.

The effect of such a construction would be, first, to reduce the velocity of the tide entering the lion's gate from about seven knots to one and a half or two knots an hour; that is, to reduce the current to one-third of its present velocity, thus making the harbor free of entry without danger even to the smallest craft at any stage of the tide.



Map of Burrard Inlet.

This would have the effect of changing the Inlet above the Second Narrows from an arm of the sea into a vast wet basin of fresh water, since the many streams flowing into the Inlet would not only drive out the salt water from above the Second Narrows, but would most likely have the effect of freshening the then limited area of water in Vancouver Harbor to such an extent as to entirely check the ravages of the teredo navalis.

The suggested sea-wall would be provided with locks of sufficient capacity to accommodate the largest ships. It would be provided with graving docks, with subways for electric power lines and aqueducts. On the surface would be tramways, and a railway for the common use of railroads entering Vancouver, obviating the necessity for the intended railroad cantilever bridge across the Narrows, and would very likely render unnecessary the projected improvements to the channel of the lion's gate. Moreover, by giving ships access to fresh water it would make it possible to clear them of barnacles and other impediments in the cheapest manner.

By the aid of this sea-wall the water above could be maintained at or about the present level of high water, and would consequently simplify the matter of stevedoring and wharf-building throughout the upper arm of Burrard Inlet.

This highwater level would also render the upper arm navigable to the largest ships, and would in time undoubtedly have the effect of promoting manufacturing enterprises on lands free from the taxes of a large city and yet within reach, by tram or train, of the working classes residing there.

The people and the factories cannot exist together in perfect conditions of health. In every large town the factories are crowding the residences further and further into the suburbs, and Vancouver must now decide whether she will gradually give up her unrivalled and beautiful situation to the demands of commerce or whether she will provide for a vaster commerce and a healthful people, by encouraging the establishment of industries without her gates and yet within reach of her workers.

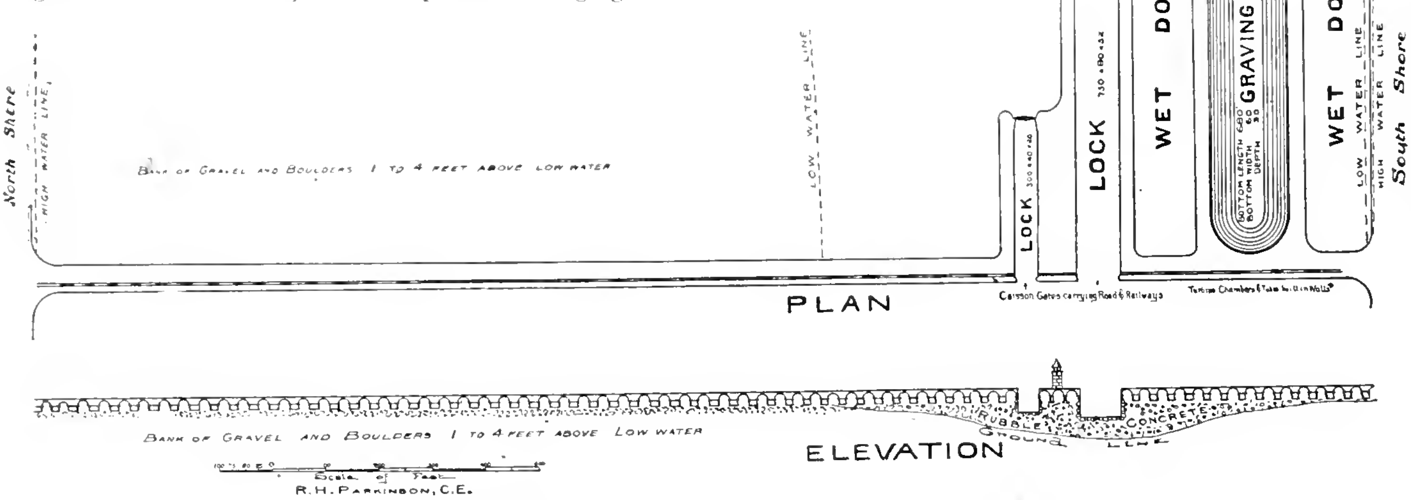
Vancouver rejoices in the mildest winter of any port in Canada. Burrard Inlet is free from ice at all times. The water is clear and free from silt, and the streams flowing into it are mostly of the nature of mountain cataracts, which descend through rocky canyons and carry very little wash with them. The sea-wall and docks suggested would therefore have very little silt to contend with.

The south shore of the Second Narrows is bedrock, which probably extends the greater part of the distance across. If this is the case, then the cost of the proposed works will be far less than the cost of works of the same magnitude built elsewhere, for the expense of dredging will not be encountered, except in the gravel bank on the north shore, and this is dry at low water. To find the cost of the proposed works will therefore be largely a calculation of the cost of so many cubic yards of reinforced concrete, to be laid under rather difficult conditions; together with the cost of the necessary caisson gates for the locks and bridges for the railways and highway. The main wall and dock walls shown on the plan are from 30 to 50 feet wide on the surface; these widths are, of course, excessive as far as strength is concerned, and they may be constructed of parallel walls of ten feet in thickness, filled in with boulders or joined at the tops by arches or girders to form the floor of the quay. It would be advisable to build in the walls tubes of over six feet in diameter, which could be used for such purposes as aqueducts and conveyers of electric high-voltage wires. Cross tubes would be provided in the main wall for spillway and also chambers about low-water level for turbines, the water supply for which could be taken in at the foot of the pier ends and thence through tubes laid in the dock walls to the turbine chambers.

The filling and emptying conduits of the docks and dry docks would require to be of large aggregate area, so that when all these voids in the walls are accounted for the volume of concrete used in construction would not exceed one-third of the gross bulk of the walls and piers shown on the plan, and this volume could be reduced by filling in the walls with boulders, of which there is a plentiful supply along the north shore.

Roughly the gross volume of rubble and reinforced concrete required for the works shown would be about 400,000 cubic yards, the average cost of which should not exceed $6 a cubic yard. Therefore, with caissons, tracks, turbines and other equipment the total cost of the proposed works should not greatly exceed two and a half million dollars.

When it is considered that the Esquimalt dry dock (475 feet long, built of masonry) cost three million dollars, one can realize the great advantage which the site of the proposed dry dock possesses, as it is designed to be built at a point where the rock bed of the Inlet lies at just a sufficient depth (35 feet) below high water, which would be the permanent level of the upper inlet, thus requiring only the retaining walls and altars to be built of concrete at a cost less than that of the Port Orchard, California, dry dock (675 feet long), which is built of timber, faced with concrete, at a cost of $600,000, and is at present the largest dry dock on the Pacific Coast.



Suggested Sea-Wall at Second Narrows, Vancouver Harbor.

The writer has at present nothing but an Admiralty chart and his own observation (during a three years' residence in Vancouver) of the existing conditions to guide him in this design, and it would be necessary, of course, to make a careful survey of the site of the proposed sea-wall in order to prove the nature of the channel-bed and the exact dimensions of the channel, before a proper design could be prepared or an accurate estimate of the cost determined.

The proposed works might well be located at the First Narrows, were it not for the delay which would be caused to the passenger traffic.

As an investment of capital the proposed works should pay well, since the tram and railway tolls and harbor dues should amount in the course of a few years to enough to pay a good percentage on the investment.

But the competition of the United States ports to the south makes it important that Vancouver Harbor should be made attractive to shipping, and even if the works were toll free and dues free, the enormous impetus they would give to Canadian ocean traffic and to manufacturing enterprises would be a vast gain to the Dominion, not to be measured merely in dollars and cents, but in commerce and population—in enterprise and prosperity.

CONTENTS OF THIS ISSUE.

TORONTO'S WATER SUPPLY: FROM SCARBORO OR CENTRE ISLAND?

The editorial on Toronto's Water By-law, which appeared in these columns in the issue of December 26th, has been productive of criticism on the part of Mr. Isham Randolph and Mr. Willis Chipman, who are members of the Board of Water Commissioners, which Commission recommended the establishment of the duplicate water plant for Toronto at Scarboro Bluffs.

Our criticisms of their report were made from facts, and, as is obvious, were intended in no sense as a personal attack on these gentlemen. Mr. Randolph, of Chicago, however, in commenting on the editorial, through the medium of the daily press, states that: "Now, personally, *The Canadian Engineer* carries no weight with me. Its editors do not impress me as being fair-minded." His attitude is due, no doubt, to the fact that several times during the past year we have had occasion to comment unfavorably on reports and recommendations made by him on other matters. A reference to the files of *The Canadian Engineer* will make clear why Mr. Randolph does not feel that we are fair-minded. A perusal of these editorials will give the reader the opportunity of judging for himself on that question.

The following quotation, made from Mr. Randolph's criticism, exemplifies very clearly his attitude of mind (or shall we say of "I") upon which we commented, with regard to his report on the Chicago Drainage Canal: "**I** have to deal with such a variety of questions that **I** fear **I** have the habit of relieving **my** mind of the whys and wherefores that have influenced **my** conclusion upon a subject, when once that conclusion is reached and announced; so, feeling mentally freer to tackle the next question with which **I** have to deal."

In the Toronto Star of December 26th Mr. Chipman states that in the Scarboro scheme the water will only need to be pumped once, and that the cost of pumping the water twice from the Centre Island plant would be more than the extra cost occasioned by the extra lift. Evidently, Mr. Chipman had forgotten the comments made on page 14 of the Board of Commissioners' report, in which it is stated that: "West Toronto will thus be supplied from the Scarboro reservoir by gravity. For the higher districts lying north of Davenport Road and the easterly branch of the Don it will be necessary to re-pump the water required, and, as this district is rapidly increasing in population, additions to the pumping machinery will be frequently demanded."

In the Toronto Telegram of December 27th Mr. Chipman states: "We do not say that continuous filtration is absolutely necessary. There is a possibility that filtration will not be required there (at Scarboro) all the time. We believe that there are times when neither filtration nor chlorination will be necessary." Evidently, Mr. Chipman has revised his opinion since the report of the Board of Commissioners was made, for on page 13 of the report it is stated that: "It should be borne in mind that bodies of infected water are floating in the lake, and to guard against the possibility of danger from this source it is advisable that the water should at all times be filtered."

We have no desire to engage in a controversy over the relative merits of Scarboro or Centre Island as a source of supply. In our previous editorial we presented certain facts, and these facts have been questioned by members of the Commission and others. The facts demand that an unbiased and unprejudiced view of the whole matter be presented.

The statement is often repeated, both by the Commissioners and by the public, that there is a greater probability of obtaining purer water for greater lengths of time at Scarboro than at Centre Island. On page 71 of the report the Board of Commissioners state that the transporting currents depend entirely upon the wind. The results of certain experiments made in the year 1909, by City Engineer Rust, and given on page 76 of the Commissioners' report, were that "the net result of our observations is that the wind controls the current, and that during the last year the wind blew away from the present intake 68.9 per cent. of the time." Records of the Meteorological Service show that the greater proportion of winds at Toronto come from the west.

With these facts clearly in mind, it is hard to understand Mr. Chipman's statement that it will not be necessary to filter at all times at Scarboro.

It is agreed by the Commissioners that it will cost more to pump the water at Scarboro than it will at Centre Island, but they claim that this extra cost will be off-set by the fact that he Centre Island has to be pumped twice under present conditions. Yet, they expressly state that "booster" pumping stations will be required throughout the city on the feeder from Scarboro.

The serious defect in the Scarboro scheme, more serious than the question of first cost or the question of operating cost, is the defect which is common to all gravity systems; and it might well be questioned whether it would be advisable to use Scarboro as a source of supply, even if it was unnecessary to raise the water 330 feet from lake level to the elevation of Scarboro Bluffs. This defect is the fact that the elevation of the reservoir at Scarboro, with the gravity pipe line feeder, absolutely fixes the amount of energy present in the system. That is, when no water is flowing through the gravity line the pressure head will stand at the level of the reservoir. When the demand increases the head drops as the friction loss increases, until at the point of maximum water demand the minimum head is available. There is no way of controlling this variation in the pressure in a gravity system, and the result is the most undesirable condition of maximum demand and minimum pressure. On the other hand, with the present pumping system, as the demand increases, more energy is put into the system by increasing the pumping capacity, and, therefore, the pressure can be kept at almost a constant.

This fact in favor of the pumping system cannot be too strongly emphasized. It is a matter which has been entirely overlooked in the Board of Commissioners' report. To show what the result would be, it is only necessary to take an example. Mr. Chipman states in the Toronto Telegram of December 27th that with the maximum demand there will be a loss of head of about seven feet in the mile. That is, at the present high-level pumping station there will be a loss of 84 feet of head under conditions of maximum load. When there is no demand for water the pressure level will be at the elevation of the Scarboro reservoir. This will mean that the house services in that neighborhood are subjected to a daily variation in pressure of 84 feet. At West Toronto conditions will be far worse than this unless "booster" pumps are used. It would be interesting to know if the Commissioners had at all considered this variation in pressure. It would also be interesting to know how they intended to control the excess pressure in the east end where the ground level is 250 to 275 feet below the elevation of the Scarboro reservoir.

The absolute lack of flexibility of a gravity scheme such as that from Scarboro, together with its greater first cost and the greater continuous cost of operation, demands the city's consideration of a duplicate Centre Island plant.

LETTER TO THE EDITOR.

DESCRIPTIONS OF LAND.

Sir,—I send you herewith copy of description taken from deed of a lot of land in New Brunswick. This is a fair sample of hundreds of descriptions still used in that province.

The registration system is antiquated and, as there is no complete system of lot numbers, a separate index for each lot is not used in the registry offices.

This entails enormous waste of time and money in making searches against titles and uncertainty as to completeness.

It would be a decided benefit to land owners in New Brunswick if the Dominion Government would apply part of the annual subsidy to establishing a registry system similar to the Cadastral system in Quebec province.

The Provincial Government seems to be helpless in the matter.

Yours truly,

H. IRWIN, Q.L.S.

370 Kensington Avenue, Westmount, P.Q., 28th Dec., 1912.

Description.

"All that certain lot of land situate in the Parish of Douglas . . . bounded and described . . . as follows: On the south by the Saint John River, extending eastward to an oak tree near a brook, thence northerly to a hemlock tree near the highway road, thence westerly to a willow tree on the north side of the said road; thence northward to a cedar post near a brook; thence following the said brook to near the head, and so on to a spruce tree on Hallett's line, and thence following the said Hallett's line to the oak tree aforesaid on the bank of the River St. John, being the same lot of land conveyed to the said Thomas E. Wheeler by Charles J. Tozier."

GENERAL NOTES.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for December, 1912:

	Depth in inches.	Departure from the average of twenty years
Calgary, Alta.	...	......
Edmonton, Alta.	0.1	—0.70
Swift Current, Sask.	0.3	—0.42
Winnipeg, Man.	...	......

Victoria, B.C.	5.8	—0.47
Kamloops, B.C.	0.5	—0.32

REINFORCED CONCRETE ELEVATED WATER TANK AT BERLIN, ONTARIO.

Although elevated water tanks were the first important reinforced concrete structures built in Europe and although there are some railroad tanks made of this material still in existence which were built over fifty years ago, the construction of large elevated water tanks for municipal use is still something of a novelty in this country. The following description and illustrations of reinforced concrete tank recently completed at Berlin, Ontario, are taken from a recent issue of "Engineering-Contracting," to whom acknowledgement is here made:—

The capacities and heights of elevated tanks are increasing each year. With increase in size, economical design of the bottom and supports of elevated concrete tanks becomes highly important, since the cost of these parts of such structures is by far the greatest item of expense in building a tank of this character. The ordinary girder and slab construction for the bottom of large tanks is a very expensive feature in concrete tank construction. Loads of from 1,000 to 3,000 lbs. per sq. ft. require very heavy beams and slabs and a great many supports. There is no more ideal design for tank bottoms than the dome and frustum shape bottom as shown in the illustrations here given.

Concrete, being an ideal building material for compression, is strained to its best advantage in this type. The inner dome is under compression in every direction, and the frustum or outer dome is in compression in one direction and in tension from water pressure in the other direction. At the junction of the inverted dome and the inner dome, the thrust from these two domes may be balanced by the adoption of proper inclinations and sizes of the domes, or there may exist a tension in the ring by the thrust of the inner dome being greater than the thrust of the outer dome, or there may exist a compression caused by the thrust of the outer dome being greater than that of the inner dome. In most cases there is at this region a very massive ring of concrete to take care of eventual changing conditions, for the tank empty, for the tank half full, or for the tank filled to its top. This ring may be supported by four or more columns according to the size of the tank, in which case the ring must serve also as a girder and must be designed accordingly. On account of the comparatively small spans and great loads, these girders are designed mostly for shear and less for bending, and it thereby lends itself readily to architectural treatment, as the rational form of such a grider is really an arch on top of the support. Where only four columns are used, this grider is subjected to a considerable torsional moment, and must be designed accordingly.

Another way of supporting the ring at the junction of the two domes is to support it on a shell of concrete, or, as it is preferred in Europe, of brick or stone. If the shell is built of brick or stone, it is rarely made less than 18 to 24 ins. thick, and, although offering opportunity for elegant architectural treatment, it is very much more expensive than reinforced concrete shells, which can be made very much thinner.

A very cuch larger tank of the second type was recently designed and built by Mr. Mensch for the city of Berlin, Ontario. The construction of this tank was begun in August and completed in November of this year. The tank has a capacity of 600,000 U.S. gals. The details of design of the tank are shown in Figs. 1 and 2.

As will be seen from Fig. 1, the tank is supported by a reinforced concrete shell 75 ft. 11 ins. high and 12 ins. thick. This supporting shell rests upon a circular beveled ring foundation 13 ft. wide on its base and 18 ins. wide on its upper face. The two main parts of the tank bottom are referred to as the inner and outer domes. The inner dome is a portion of the surface of a sphere of 27 ft. radius. The outer dome is the frustum of a right circular cone. The inner and outer domes intersect at the top of the supporting cylindrical shell. The tank proper is 50 ft. in inside diameter. The depth of water in the tank when full is 39 ft., measured from the median plane of the base to the elevation of the overflow. The tank shell is a cylinder 41 ft. high with 12-in. walls. The roof is a portion of a spherical surface 4 ins. thick. The total height of the structure from the top of the foundation ring to the top of the roof is 127 ft. 4 ins.

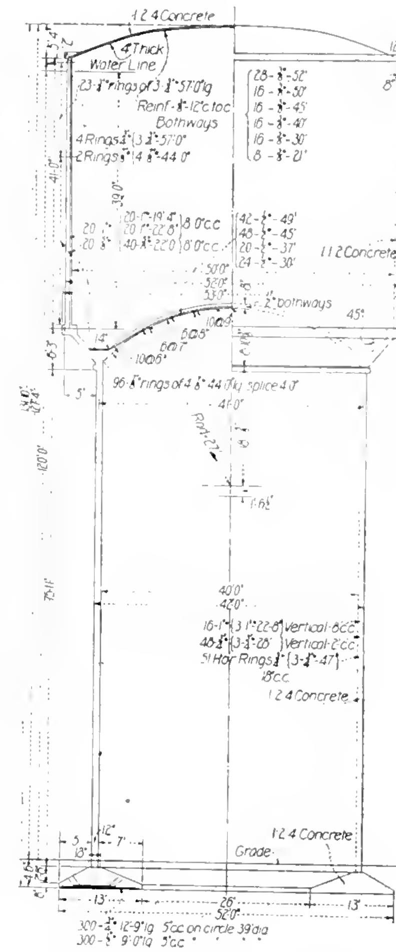

Fig. 1. Sectional Elevation of Concrete Water Tank for Berlin, Ont.

The supporting shell is made incidentally to house a booster pumping unit composed of a turbine pump direct connected to an electric motor. This pump is held in reserve for use in case of very heavy water consumption when the pressure on the mains produced by the head of water in the tank may become insufficient in the higher zones of the distribution system. This pump is placed in operation by automatic electric control from a remote point. In addition to the pumping unit the supporting shell houses the regulating device which controls the admission of water to the tank.

The lower shell is provided with a door and several windows. The ladder to the tank rises from the floor of the pump-room and extends, inside the supporting shell, to an opening 2 ft. 6 ins. by 5 ft., which is made in the shell just below the tank bottom. Outside the shell at the level of the bottom of this opening there is a platform 2 ft. 6 ins. by 7 ft., which is supported on brackets from the shell. An outside ladder extends from this platform to a manhole opening in the roof of the tank.

The inner dome varies in thickness from 14 ins. to 8 ins. The outer dome varies from 12 ins. to 10 ins. A large scale detail drawing of the intersection of the two domes is shown herewith in Fig. 2. These two domes are so proportioned that their thrusts nearly balance. At the junction of the outer dome and shell of the tank there exists a great outward thrust from the weight of the shell of the tank and of the roof, which necessitated the placing of a large amount of steel, and in order to secure the co-operation of the steel and the concrete there was provided a section of concrete at this junction of 18 ins. by 30 ins.

The reinforcing of the tank consisted of ⅞-in. and ¾-in. square bars of high carbon steel. They are placed in two

separate layers where the spacing is less than 4 ins. At the junction of the two domes, a great excess of concrete was provided to take care of the thurst of the outer dome while the tank was empty or partially full. The reinforcing of the inner dome consists of ½-in. rods placed on 6 to 8-in. centres. These rods were provided to take care of stresses, due to the elastic deformation; otherwise the dome is stressed in both directions in compression only, and would not require any reinforcing.

A mixture of concrete of 1:1:2, or slightly richer, was used in all portions of the tank in direct contact with the water. All other concrete consisted of a mixture of 1:2:4. The lower sheel was built by means of wooden forms 6 ft. deep, which were suspended from 1-in. rods imbedded in the concrete, and 8 ft. apart. These 1-in. rods served as a support for a hollow screw, the turning of which moved the forms up. It was found, however, that not more than 4 to 6 ft. could be concreted in any day.

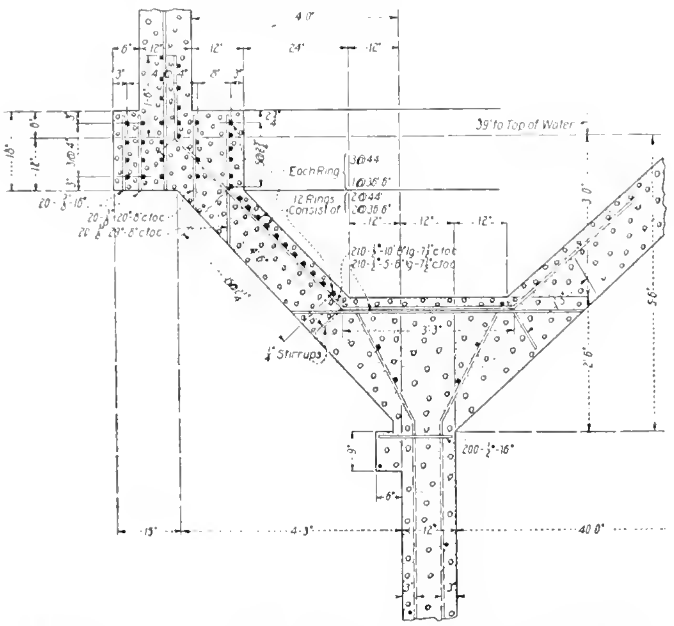

Fig. 2.—Detail of Concrete Reinforcement at Intersections of Outer Dome, with Inner Dome and Tank Wall.

The forms for the inner dome and outer dome were supported on 6-in. by 6-in. Norway pine posts about 10 ft. centre to centre. The forms for the concrete tank were built of 20 sections 3 ft. 1 in. high and 8 ft. long. The outside forms were kept from spreading by common tank hoops. Two sets of these forms were used, one on top of the other, so that one form always served to support the next while being set up

In order to prevent a leak at the junction of two days' work, due to careless removal of laitance or insufficient tamping of the new concrete, a dam or sheet steel 6 ins. wide and No. 28 gauge was imbedded 3 ins. in the concrete at the end of each day's work. These dams came in lengths of 82 ft., which is one-half the circumference of the tank. The roof forms were supported on 4-in. by 4-in. uprights about 8 ft. centre to centre. As they were 44 ft. long, they were braced in two directions every 10 ft.

The concrete plant consisted of a Chain Belt mixer placed near the centre of the tank, which discharged the concrete into a hoisting bucket. The bucket ran inside of a wooden tower, which was built of four 4-in. by 6-in. uprights suitably braced and 140 ft. high. It was raised by means of a hoisting engine placed about 50 ft. from the centre of the tank and outside of the structure. The hoisting bucket discharged the concrete into a hopper, which was also placed inside of the hoisting tower, and from here was spouted through a system of pipes and flexible spouts into place. The hoisting tower placed in the centre necessitated an opening in the bottom and the roof of the tank. These openings were closed and concreted after the rest of the structure was finished. The contract cost of the tank was $23,500.

In the opinion of Mr. Mensch designer and builder of this tank, there are two reasons for the comparatively rare use of concrete for elevated tanks, namely:—

First, because of the inexperience of engineers and contractors in designing and building an absolute water-tight structure of concrete. In a reservoir, which is placed on the ground, wet spots in the walls, or even slight leaks, are not very objectionable, while in elevated structures they are sources of danger from frost, and decidedly unsightly. While wet spots and slight leaks are often overlooked in wooden and steel tanks, they are sources of anxiety in concrete tanks.

Second, because the cost of a concrete structure of this character is, as a rule, considerably higher than that of a steel structure.

Elevated concrete tanks possess some points of advantage, however, over steel tanks. An important advantage of concrete tanks for service in northern climates is that their thick walls prevent, to a considerable extent, the formation of ice within the tank. Under unfavorable conditions of weather and protection from freezing, ice formed within large tanks sometimes attains a thickness of 5 ft. or more. Other points of advantage of concrete tanks are that they do not require painting, and that from the nature of the construction material employed ornamental effects are readily available for slight additional cost.

The tank herein described was built as one part of the extensive improvements to the water works system of Berlin, which have been made during the past year. Messrs. Bowman and Connor Consulting Engineers, of Berlin and Toronto, planned these improvements, with the exception of the water tank. The design of the tank was checked by Mr. Connor.

The length of the Esquimalt Graving Dock at Victoria dock to gate is 450 feet, level with keel blocks; 480 feet with gate on outer kerb. The width of gates is 65 feet. The depth of water varies from 27 feet to 29 feet 6 inches at springs, according to the season of year. The use of the dock will be subject to the following tariff:—

Gross tonnage of vessel.	For the first day of docking.	For each following day, including undocking day.
For all vessels up to 1,000 tons	$300.00	5 cents per ton.
From 1,000 to 2,000 tons	350.00	4½ cents per ton.
For all vessels above 2,000 tons	400.00	4 cents per ton up to 2,000 tons and 2 cts. per ton on all tonnage above 2,000.
Vessels from 430 to 450 ft. in length	550.00	
Vessels from 450 to 480 ft. in length	700.00	

Possessing a large quantity of paper-making woods, British Columbia affords a promising field for the paper-maker. Pulpwood forests border the ocean and many navigable waters, simplifying transportation, and there are numerous water-powers to supply motive power to the mills. The rapid denudation of the pulp areas of the United States will soon compel it to look to Canada for its supply of wood pulp, which, according to the regulations now in force, must be manufactured in the province. There is, besides, a present demand for pulp in Japan, China and Australia, and when the industry is fairly developed, the ocean freights will enable profitable exportation to Great Britain and Europe.

SEWAGE DISPOSAL.*

By J. Darlington Whitmore.

In preparing this paper on Sewage Disposal, I have not considered it necessary to review all the various methods now adopted, but have confined my remarks to that method which seems most applicable to our province and peculiar local conditions, and as this is a maiden paper for a maiden society I must ask your forbearance for any maidenly coyness that may permeate the following lines.

Sewage disposal methods rightly commence on the property of the producer, and I therefore propose to glance lightly over an imaginary scheme, commencing at an imaginary household and following the sewage to its reception and treatment at the disposal works.

I shall not in this present paper deal with other than water borne sewage; the outside closet and privy, etc., together with the objectionable methods of emptying and cleansing same, being thoroughly familiar to us all.

As you are all no doubt aware, the close of the year 1909 saw the ratification of a very excellent Public Health Act for this province, patterned largely upon the laws and regulations enforced by the various local government boards of Great Britain, and controlling the methods of sewage disposal and water supply, as also the pollution of streams and waterways.

The authority is vested in a "Bureau of Health" acting for the government and having a duly qualified medical man at its head as commissioner, who in turn has a sanitary engineer on his staff to advise with him on the various questions that arise.

No scheme for water supply, sewage disposal or sewerage can now be constructed in this province without the sanction of this body, and as time passes and the various plants now completed or under construction come into use, much valuable information will be obtained, and a careful record of regular tests and analyses at the various works will further enlarge our knowledge of this subject and enable us to take a seat in the forefront in the vexed question of the efficient and sanitary disposal of sewage.

Plumbing.—Commencing with the household, our first step in connection with sewage disposal is to install satisfactory plumbing whereby the liquid wastes and fæcal matters are quickly passed away into the sewers without causing any nuisance to the occupiers of the premises.

It has been abundantly proved that, where perfect ventilation in the plumbing system does not exist, the foul gases generated by the sewage and ever present in the pipes will force their way through the water seal of the traps to the interior of the dwelling with a consequence of disease and sometimes death to those persons inhaling the impure mixture.

It is, therefore, absolutely necessary to arrange for perfect ventilation to the whole system and in each case all traps should be back vented with efficient vent pipes and every fixture should be trapped.

The system in vogue for many years, of placing an intercepting trap on each individual system, thereby separating the house plumbing from the sewers, has not borne out the expectations conceived for it and the majority of new systems being or to be installed will be without this fixture.

The idea governing the adoption of the intercepting trap was to exclude sewer gases in the main sewers from rising into habited premises and also to prevent the ingress of rodents; each separate plumbing system was then vented on the house side of the intercepting trap, and it was for a long time considered that the acme of plumbing ventilation had been achieved.

A short vent pipe was connected with the house system close to the intercepting trap, generally in a manhole, whilst the main soil pipe was continued up above the roof; the idea being that the short pipe would always act as an inlet and the long one as an outlet.

This theory was, however, soon exploded, it being discovered that both long and short pipes acted alternately as inlet and outlet, depending upon changes of wind, temperature, etc., and, as the short pipe was always at the lower end of the system, extremely foul odors were ofter discharged at most dangerous points to passing pedestrians, and, where open windows or doors were near the supposed inlet, the malicious influence of the sewer air soon became only too well manifest.

To overcome these difficulties at the supposed inlet end various valves were made, the chief kind being fitted with a mica flap to allow air to enter from outside but to prevent foul air emanating from within; the success attending the adoption of these expedients was but meagre and unsatisfactory and the adoption of this system cannot be recommended.

Personally I consider that efficient plumbing in the interior of dwellings should be as follows: The soil, waste and vent pipes should be of iron, with the caulked lead joint, all fixtures such as baths, sinks, closets, grease traps, etc., should be of porcelain, and through ventilation with the main sewers be always acting; all traps to all fixtures being vented into either a separate anti-syphonage pipe or into the main soil pipe well above the highest fixture; further, the soil pipe should be carried up well above the ridge of the roof and should discharge clear of all chimneys or open windows.

To be certain of satisfactory and air-tight joints in the plumbing at least two tests are necessary, the hydraulic and smoke test. The hydraulic or roughing in test is applied before the fixtures are installed; the pipes including soil, waste and vents being filled with water and allowed to stand a reasonable time; after this test is satisfactorily accomplished and any faults made good, the fixtures are placed, and a smoke test of sufficient pressure so as just not to break the trap seals is further applied; the plumbing after satisfactorily passing these two tests being ready for use.

Sewers.—The sewers can be of either concrete, vitrified tile, vitrified brick or other impervious and smooth construction, and should be so designed as to grade and size as to be self-cleansing.

The velocities of the sewage through the sewers should range from two to six feet per second when flowing half full, and wherever possible should flow by gravity without the aid of pumping.

Where, owing to the topography of the ground, lifting is necessary, it can be accomplished either by some of the various pneumatic devices now on the market or by centrifugal pumps; reciprocating or plunger pumps are not satisfactory for this purpose owing to the excessive wear on the valves and pistons, etc.

In this province the tendency is towards the separate system; the storm water being carried in separate pipes, the advantage of the separate system being that the disposal works can be designed to deal with a known quantity of sewage, and much of the expense and uncertainty attaching to combined systems is thus eliminated.

The ventilation of the sewers is an important feature and should be achieved by through ventilation with all house or

* Paper delivered before Regina Engineering Society, Regina, Sask.

other connections; every separate house connection being untrapped on the main line and thus permitting a free flow of air from the sewers through the house plumbing to the outer air or vice versâ.

It is only reasonable that each householder contaminating the sewers should also provide a means of ventilating them, and without a doubt this offers the best method of ventilation providing the soil pipes are carried up well above the ridge of the roof of any dwelling, and the plumbing is kept in good condition, for which safeguard a compulsory yearly inspection of the plumbing would be advisable.

The practice of ventilating the sewers at the street level through perforated manhole covers as adhered to by many cities and towns, cannot be too strongly condemned, the nuisance arising from such methods being too palpable to the senses of sight and smell.

Up to within about eight years ago I was a firm advocate of the intercepting trap and the ventilation of sewers at the street level, but later observation has changed my views, and I do not consider that any community adopting these methods to-day can be considered as otherwise than behind the times and disregardful of the most obvious laws of health.

Anyone who has walked along the streets of a city or town where the sewers have been ventilated at the street level must have noticed in winter the dense, unhealthy vapor that arises, and in summer they cannot have failed to have become convinced through their olfactory nerves of the monstrosity of this method and its great menace to health and life.

The inhalation of sewer gas will not of itself bring disease unless the sewage is sprayed in it, but it will undoubtedly lower the vitality of the human frame, and so render the body subject to speedy capitulation to the many forms of disease that we humans are heir to.

By ventilating the sewers through the house plumbing the obnoxious gases are carried well up into the air above the roof tops, each house system acting alternately as inlet or outlet, dependent upon the direction of the wind or degree of temperature, and thus carried far away and purified by dilution.

Disposal Works.—The aim of the provincial authorities is to prevent any septic action taking place at the disposal works, and with this end in view the ordinary septic tank is not countenanced, but plain sedimentation has been enforced in all the systems designed under the new Act up to the present time.

This is a very laudable ambition, as a non-septic effluent can be better treated on the bacteriological filters than can a septic fluid, but I do not see how these conditions are to prevail all the year round with our present designs taking into consideration the extreme severity and duration of our winter months.

Beginning with the freeze-up in November, our winters may be said not to terminate till well on into April, and during that period we experience temperatures as low or lower than 50 degrees below zero.

During this period of low temperature it does not appear to me to be either advisable or feasible to empty the sludge from the sedimentation tanks on to the sludge beds as even if the sludge were thus deposited it would freeze into a solid mass and thus neither drain nor dry, whilst it is more than probable that the sludge pipes leading from the sedimentation tanks to the sludge beds would, when operated, quickly become frozen and fail to accomplish their object.

With fresh frozen sludge being deposited on the sludge beds from time to time during the winter, a great mass would accumulate which would take a long time to drain and dry after the winter was over, if it ever did dry, and, I am afraid, would materially interfere with and retard the successful operation of the plant.

If, on the other hand, the sludge is allowed to remain collecting in the sedimentation tanks during the winter months, it will become septic, and the professed object of the provincial authorities will not be obtained with the sedimentation tanks as at present designed.

Fresh sludge from a sedimentation tank contains from 90 per cent. to 95 per cent. water, whereas sludge that is septic contains only 80 per cent. water; it is therefore easy to understand that the removal and subsequent treatment of septic sludge entails much less labor and costs considerably less than that of fresh sludge.

Having in mind the duration and severity of our winters and the difference in volume of fresh wet sludge as against wet septic sludge, I am in favor of a tank so designed that the sludge can be retained for long periods and become septic without coming into long contact with the effluent passing through the tank, and the Emscher tank apparently complies with these requirements with its deep sludge well accommodation.

Septic sludge, being viscous and denser than fresh sludge, is much easier to handle, and both drains and dries quicker, becoming under normal conditions spadable in about five days after being spread upon the drying beds, whereas fresh sludge is very sloppy owing to its large content of water and does not become spadable in less than fifteen to twenty days under similar conditions; it has also a tendency to clog and choke the drainage material of which the sludge beds are composed.

In many of the larger European plants the sludge is drained and dried in pressing machines and centrifuges and afterwards pressed into cakes and used for manure on farm lands, or as fill in low lying ground or sometimes burnt; the grease is also sometimes extracted and sold, but up to the present at a financial loss in most instances

The sludge has but little value as manure and in many cases farmers or others have demanded and obtained payment for removing it from the works.

Personally I am of the opinion that in this province where farmers have not yet attempted to manure the land, that the best and most satisfactory method of disposal of sludge is to burn it in an incinerator after it has been dried upon the sludge beds to a consistency of about 50 per cent. moisture, in which condition it is easily spadable.

For the smaller communities that do not possess garbage incinerators, the dried sludge can be buried in shallow trenches in and reserved for this purpose adjoining the disposal works.

I have spoken at some length on the sludge question, as it is undoubtedly the most troublesome feature to deal with in the modern system of sewage disposal for inland communities, and there is a good sized fortune in store for that individual who can discover some better and more sanitary and economical method of sludge disposal than that which prevails to-day.

Whilst speaking of the sludge it occurs to me that up to the present no attempt has been made to control the fly nuisance that will arise whilst the sludge is being drained and dried upon the beds.

Residual oils sprayed upon the sludge will effectually prevent the fly evil, but at the same time will considerably retard the drying process, and on that account may not be advisable.

For my part, I would favor the construction of a cheap framing around the sludge beds; the openings between the

uprights being filled in with wire mosquito netting and the top roofed over with shingles, the sides having doors for the ingress and egress of the workmen for removing the dried sludge.

This construction would confine the flies to the sludge beds and prevent their wandering into human habitations, and at the same time would allow free access of light and air whilst excluding the rain; the flies could be exterminated from time to time by smoke or other methods.

The severity of our winters has made it debatable as to whether the filters will, without the aid of artificial heat, freeze during the winter months, and to overome this tendency the sedimentation tanks and filter beds have, where possible, been designed under one roof and practically within one enclosure in the hope that the latent heat in the fresh sewage will be sufficient to counteract the frost.

From my personal observations at the septic tanks at Moose Jaw, extending over a period of five years, I found that the temperature of the blanket in the tanks ranged from 40 to 45 degrees Fahr.; the lower temperature being recorded when the air outside the tank registered 40 degrees or more below zero Fahr.; the tanks being of reinforced concrete construction roofed in and covered with a dirt fill of at least two feet on the crown of the arch and increasing towards the haunches and walls.

It remains to be seen whether the latent heat of the sewage will be sufficient to overcome the tendency to freeze in the filters, and I am inclined to the belief that it will, providing proper care is observed in their construction with a view to keeping out the frost. Should the filters, however, show signs of freezing artificial heat will have to be resorted to with its attendant additional outlay and expense.

It is, of course, understood that in locating a site for a sewage disposal plant the topography of the land be well studied with a view to the avoidance of pumping with all its attendant heavy costs, that it be placed as far from the community it serves as possible, and so that the prevailing winds shall carry the odors that will arise, even in the best of plants, away from the city or town.

With this digression I will proceed to describe my imaginary disposal works, which will be typical of those installed in the province up to the present time in conformity with the requirements of the Bureau of Health.

Upon the arrival of the sewage at the works it is received in a screening chamber, passed on into a detritus chamber, thence into a sedimentation tank or system of tanks, from whence it is distributed over bacteriological filter beds, and after emerging, passed into a humus tank where it can be disinfected if necessary before being finally disposed of.

Screening Chamber.—The screening chamber is a small rectangular compartment fitted with bar screens spaced about half an inch apart, the bars being of wrought iron and 1¼ by ½ inch section; in this chamber all foreign substances such as sticks, flannels, scrubbing brushes, corks, matches, hair, etc., are caught and retained and periodically removed and buried or burnt.

Detritus Chamber.—The detritus chamber is rectangular in shape and placed between the screening chamber and the sedimentation tank, being really part of the tank, its capacity is from 3 per cent. to 5 per cent. that of the tank and its functions that of intercepting the heavier mineral matters in the sewage during its passage to the tank.

Were we sure that no sand or other mineral matter would find its way into the sewage, the detritus tank would not be necessary with our separate system of sewage, but we cannot always guarantee that the joints in the tile sewers will remain perfect and it is considered advisable to exclude these substances from the sludge of the sedimentation tanks.

The accumulation of detritus is removed at regular intervals through sludge pipes placed at the bottom of the tank, and is subsequently dried and buried.

Sedimentation Tank.—From the detritus chamber the sewage flows over a long weir into the sedimentation tank by means of a submerged inlet, the tank being so designed as to obtain a large sedimentation of the organic matter in the sewage with a continuous flow of the effluent to the filters.

The velocity of the sewage where it enters the screening chamber is three feet per second, but in the tank it is reduced to one-sixty-fourth of an inch per second, which gives us practically quiescent sedimentation with a continuous flow.

The effluent passes out to the collecting channel through submerged outlets, and no scum boards are used, as their adoption tends to set up currents in the tank.

The tank I have in mind is divided into two compartments and so controlled by valves that either compartment can be used or thrown out of commission at will, thus enabling us to treat the sewage with different durations of contact, or to empty one division for inspection or cleansing at any time without disorganizing the operation of the works.

The walls and floor are trowelled smooth, the latter having a slope of one in fifteen to the shallow sludge pits, to facilitate the gravitation of the sludge.

The rate of flow through the tank is four and three hours respectively, so that if desired for experimental purposes rates of flow of three, four and seven hours can be obtained. The amount of dried sludge extracted from the tank per capita per day is approximately two ounces, depending, of course, largely upon the habits of the persons contributing to the sewage, and as this is increased in bulk nineteen or twenty times by the large amount of water mixed with it, being approximately in the mass 90 degrees to 95 degrees water, weekly extraction of the sludge is necessary to keep the effluent fresh.

For this purpose sludge pipes controlled by cone-shaped valves are carried from the bottom of the shallow sludge pits to the sludge beds, where the sludge is regularly deposited and dried during the seasonable months.

The tank is easy of approach and is fitted with gangways inside so that inspection is at all times easy and can be accomplished without climbing down dark and dirty manholes, or soiling the hands or clothing.

The tank is of reinforced concrete and roofed in as is indeed all other parts of the plant, and a thermometer is kept constantly suspended in the sewage to show the degree of temperature.

The outlet of the tank is fitted with a measuring weir so that the production of sewage can be tabulated and recorded.

Bacteriological Filter.—After passing the measuring weir, the clarified effluent is conducted by a main channel running lengthwise along the centre of the filter, from which subsidiary channels branching off at right angles lead it to a system of Stoddart trays by means of which it is distributed over the filtering material in the form of fine rain drops.

The trays discharge at three inches above the filter, so that no splashing occurs and are laid perfectly level by means of thumb screws affixed to wrought iron chairs.

This method gives a very satisfactory distribution of the effluent and the Stoddart trays have the added advantage of requiring but little attention.

The filtering medium is composed of three-inch crushed stone, well screened and free from dust, and has an average depth of 8 feet, for treating the effluent at the rate of 150 Imperial gallons per cubic yard per 24 hours.

The floor of the filter is of concrete, trowelled smooth with a fall of 1 in 30 towards the centre channel, where the filtered effluent is collected and discharged.

Upon the floor rocks of about 9-inch to 12-inch section are laid to admit of free access of air and easy drainage, and provision for an efficient circulation of air through the filter is further obtained by carrying down from above the ground a set of 12-inch diameter inlet pipes which discharge into the base of the filter and are spaced at 25-foot intervals longitudinally around the walls.

The roof of the filter is further fitted with ventilators for discharging the air, so that good aeration and ventilation are obtained.

Sunlight is admitted through windows in the roof, which are kept open in the summer and closed during winter. The action of this type of continuous filter is aerobic and the degree of purification obtained about 98 per cent.

All operating parts of the filter are of easy and comfortable access and an arched passageway runs along the centre of the filter for its full depth, so that inspection of the collecting channel is obtainable at all times with the aid of a covered lantern.

Disinfecting Channel.—From the filter the now considerably purified effluent is conducted into a long, rectangular channel fitted at intervals with baffle plates, where, if the circumstances so demand, it is disinfected by a minute solution of calcium hydrochlorite which, by means of the baffle plates, is thoroughly incorporated into the effluent, and the whole fully aerated.

Humus Tank.—From the disinfecting channel the effluent flows into a rectangular tank of shallow depth, divided into two longitudinal sections, where it deposits any humus that it may have carried with it during its progress of purification, and from thence is discharged into a small watercourse in a non-putrescible condition, dangerous neither to animal nor fish life.

The tank is fitted with an overfall weir and also floating arms, and one division can be thrown out of use and cleaned whilst the other is operating.

The time of the passage through the tank is twenty minutes to allow of sufficient period for the disinfectant to act.

Sludge Drying Beds.—The sludge drying beds are rectangular in shape, with wide passage ways for the convenience of the workmen who attend to the duties of spreading and drying the sludge and afterwards removing it.

The floors and walls are of reinforced wire mesh concrete to take up the thermal changes, and the floor is laid with a fall of one in ten to the centre to facilitate drainage.

Upon the floor are placed diagonal rows of 4-inch open tile pipes connecting with and discharging into the main connecting channel.

Upon these 18 inches of coarse gravel or crushed stone is placed, surmounted with a six-inch covering of medium sized sand grains, making a total thickness of straining material of 24 inches.

The sludge from the sedimentation tanks and detritus chambers is gravitated to this bed in 9-inch diameter cast iron pipes, and is conducted along the beds in half open channel pipes, from whence it is spread evenly upon the beds in six-inch layers by the workmen and left to drain and dry.

The liquid draining from the fresh sludge is highly putrescible, in contradistinction to that from septic sludge, which is not putrescible, and is conducted by means of the subdrains mentioned to pipes which convey it back to the sedimentation tanks for further treatment.

The sludge, after being dried until it becomes spadable, is removed and buried in shallow trenches upon land reserved for the purpose adjacent to the disposal works.

Conclusion.—I regret that the time at my disposal in preparing this paper has not been sufficient to enable me to prepare any drawings to illustrate my remarks, but I sincerely trust that I have made the various stages of sewage disposal operation sufficiently vivid by word pictures to counterbalance that defect.

The system explained is, as before stated, emblematical of all the new plants so far installed in this province, the only important difference being that the plants at the cities of Regina and Saskatoon have been fitted with revolving sprinkler apparatus for distribution of the effluent upon the filter beds.

In conclusion I would impress upon you that no modern sewage disposal plant, however well designed, is fool proof, and the success of each individual installation is largely dependent upon the care and skill of the attendants. A log should be kept daily of all the happenings at the works and complete records of temperatures, volumes and analyses.

CONCRETE PAVEMENTS TAMPED WITH MECHANICAL VIBRATOR.

Concrete pavements, surfaced with crushed granite and compacted to a high density by means of a mechanical vibrator, have been laid in certain cities in Texas. This method of road building was described by Mr. R. D. Stubbs, contracting engineer, of Dallas, in a paper presented at the ninth annual convention of the National Association of Cement Users at Pittsburgh. A summary of the paper is given below.

Concrete is delivered to the subgrade, after it has been properly shaped and rolled, by inclined chutes from a mixer. The proportions are 1 part Portland cement and 5 parts of aggregate, consisting of sharp sand and gravel. The amount of coarse aggregate passing a ¼-in. sieve should not exceed 40 per cent. nor be less than 33 per cent. The mix is made rather wet.

The surface is brought to the desired shape by means of long-handled floats, and is immediately covered with a coating of crushed granite, graded from ⅝ to 1¼ in. in size. The surface is then ready for the vibratory treatment. Platforms 20 in. wide, made of ⅝ x 4-in. strips, cleated ¼ in. apart, are then placed along or across the street and a movable vibrator is rolled over the road, compacting the concrete to a high density. As the work progresses the platforms are brought forward and the granite surfacing behind is immediately covered with sharp sand and watered. Two or three days later the sand is swept off the surface into the gutter with stiff wire brooms and the street surface is treated with Tarvia. Upon the Tarvia is spread a coating of hard stone from ¼ to ⅜ in. in size. Upon this surface is spread the sand formerly swept into the gutter. The surface is then rolled with a 500-lb. road roller and after the work is seven days old the street is opened to traffic.

Mr. Stubbs states that he employs no bituminous filled joints for the expansion of the pavement, but he does provide for contraction while the concrete is setting by placing on edge on the subgrade at intervals ¼ x 3-in. wooden strips so that these will be buried in the concrete and will occupy the bottom half of the cross section. Within 48 hours after the concrete has been laid, according to Mr. Stubbs, thin, straight lines of relief will appear over the breaker strips. These thin relief lines never exceed 1/16 in. in width. Mr. Stubbs advocates the use of these relief joints only in the case of very dense concrete, but in the case of poured concrete not compacted by vibration he does not favor their use.

THE PRESERVATION OF WOOD BY THE POWELL PROCESS.

Archæologist reports often make mention of the various tactics employed by the ancients in their endeavors to preserve wood, and especially wood that was underground. Probably the Romans brought this art to the highest state of perfection recorded in ancient writings, and this they did by charring the wood on the surface before its interment. Some buried work of the Romans has been unearthed in England after 2,000 years and found to be unaffected. This system is very good for woodwork that is hidden, but for exposed sections is not practical; thus the many preservatives now employed have been introduced with a view of preserving woods employed in the modern arts. One of the methods now being given considerable publicity in England is known as the Powell Wood Process, and is dependent on its working to a discovery made in 1902, when it was found that saccharine matter was a very desirable wood preservative.

The process consists essentially in treating the wood in a saccharine solution, for which wood has a decided affinity. The solutions vary in composition, and to them are added certain other substances to suit the special purpose for which the wood is required. When the wood has been specially dried the process is complete, and the wood is ready for immediate use.

The requisite plant consists of open tanks of suitable dimensions, heated by steam pipes; drying chambers; storage tanks for holding the liquor; trollies, etc.

The timber is not subjected to any external pressure or vacuum at any stage of the process. The wood is immersed in a solution in open tanks. This solution is gradually raised to specific temperatures for certain periods, depending on the size and density of the wood. When the process is completed the wood is removed and placed in a drying chamber. When sufficient desiccation has taken place the wood is ready for use.

The time occupied in the whole treatment, including drying, is in general a few days, though in special cases and for large-sized timber it may be extended to three or four weeks.

The action which takes place is as follows: As the temperature of the solution in which the wood is immersed is raised, the air in the wood expands and the greater portion escapes in a series of bubbles. As a saccharine solution boils at a slightly higher temperature than water, the moisture in the wood is gradually converted into vapor and escapes along with the air. During the treatment the albuminous matter in the wood is coagulated and rendered inert. In some measure this coagulation accounts for the strength of the wood being increased by the process. During immersion, and especially while cooling, the solution is readily absorbed by the wood and penetrates to every part of it.

When the process is completed it is found that the absorbed saccharine matter has been thoroughly assimilated by the tissues, and is invisible either as crystals or syrup, but chemical analysis shows its presence in the tissues, and that it is held in molecular combination with the cellular fibres of the wood.

Complete impregnation of all wood with sacharine matter is effected by this process, though some woods absorb the solution more readily than others, a heavy, close-grained wood taking longer to treat than one with an open grain. The sacharine matter, however, penerates even the hardest woods without pressure of any kind.

"The question whether the timber is impregnated throughout by this process is a most important one. From records to hand it seems that it is so, especially in the case where moderate sized scantlings have been treated."

The cost of treatment is low. For railway sleepers, paving blocks, pier piles and constructional timber generally Powellizing, from the viewpoint of cost, commands every consideration. The process has been used to a considerable extent in the treatment of railway timbers in India and Australia, where it has been found to preserve the sleepers from dry-rot and the attack of insects. A report was made following an examination of several Powellized sleepers, a portion of which reads as follows:—

	Powellized Sleepers			Untreated Sleepers		
No.	No. laid down	Date of laying in open line	Present Condition	No. laid down	Date of laying in open line	Present Condition
1	10	March, 1908	10 still left: cracking a little on top.	10	15th Apl., 1907	1 removed in July, 1910; 2 in 1911-12; 7 cracking.
2	10	Do.	10 still left: much cracked above; good underneath.	10	Do.	1 removed in 1909; 9 fair cracking rather badly.
3	10	Do.	10 still left. 1 may have to be removed this year; 9 cracked beginning from ends, otherwise fair.	10	Do.	1 removed in July, 1910; 3 in 1911-12; 6 gone badly underneath.
4	10	Do.	1 removed in 1911-12; 1 may have to be removed this year; 3 cracking from outside; 5 fair.	10	Do.	All removed in 1909. (Experiment closed.)
5	10	Do	All good; slight cracking.	10	Do.	1 removed in 1911-12; 1 may have to be removed this year; 8 very much cracked.
6	9	Sept., 1907	1 removed in 1909 and 1 in 1911-12; 7 still serviceable.	10 1	January, 1907 Sept., 1907	1 rem'v'd in 1908 and 7 in 1909. (Experiment closed in 1909.

The Powell Wood Process Syndicate, Limited, of 718 Salisbury House, London Wall, London, E.C., hold the patent rights to the Powell Wood Process.

PULP AND PAPER MAGAZINE OF CANADA.

The New Year number of this magazine, published by the Indnstrial and Educational Press, Limited, Toronto, has just come off the press in its enlarged size, and will hereafter appear twice a month, instead of monthly, as formerly. This is the first number from the pen of the new editor, A. G. McIntyre, formerly chemical engineer for Price Bros. & Co., Limited. Mr. McIntyre is a graduate of Acadia University in Arts and Science, and McGill University in Chemical Engineering, and joins this magazine after a wide engineering and paper mill experience.

The year's progress and development are fully reviewed in this number, and many valuable articles are contributed.

Mr. H. S. Ross, K.C., of Montreal, writes an able and exhaustive resume of the Workmen's Compensation Act of Quebec, with references to those of other countries.

The new mills of Price Bros. & Co., Limited, are fully described in an elaborate illustrated article by the editor. The new development of utilization of wood waste for gas producers is discussed by E. B. Archibald, B.Sc., of Montreal.

The Canadian water powers, timber regulations, pulp and paper tariffs, exports and imports, and the entire condition of the trade and its many ramifications are thoroughly dealt with. All this, with the numerous specially contributed technical articles for pulp and paper mill men, combine to make the Pulp and Paper Magazine a true fulfilment of its heading, "A magazine devoted to the science and practice of the manufacture of pulp and paper, with up-to-date news of the allied trades."

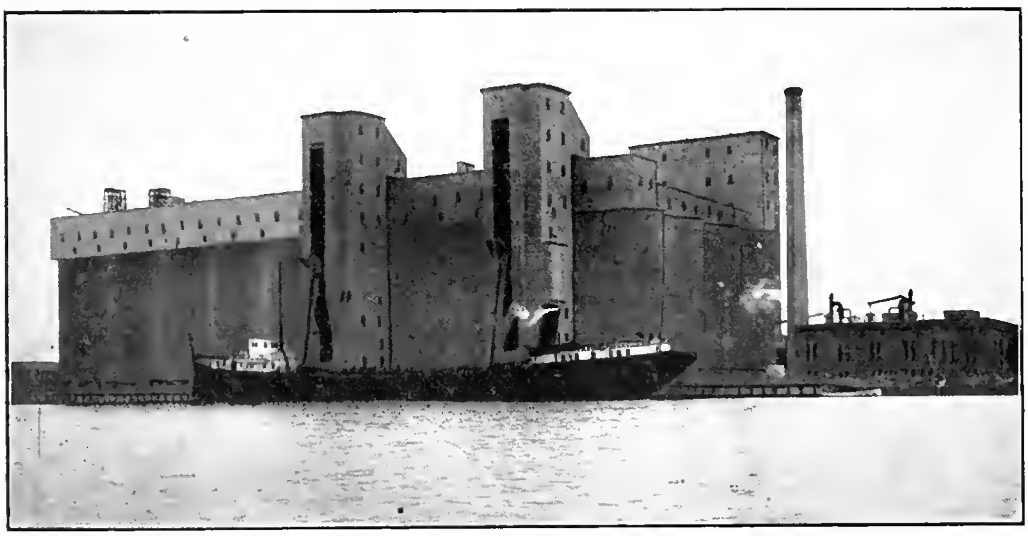
FOUR MILLION BUSHEL ELEVATOR AT PORT McNICHOLL, ONTARIO.

Some time ago we described and illustrated a 2,000,000-bushel elevator which was completed in 1910 by the John S. Metcalf Company, Limited, Montreal and Chicago, for the Canadian Pacific Railway at their new Georgian Bay terminal, Port McNicoll, Ontario. The business proved too large for the elevator by the time the latter had been in operation one year only; and the same engineers were accordingly instructed to build an additional storage unit of the same capacity as the original elevator, making the total capacity 4,000,000 bushels.

The new storage unit, which was completed in time to be entirely filled with the 1911 crop before the close of lake navigation, is a duplicate of the first. It is 179 feet wide, and 226 feet long, making the new length of the elevator 452 feet. Each unit contains 32 cylindrical bins 32 feet 11 inches in diameter, and 31 interspace bins; the bin walls are 80 feet high.

The entire structure is of steel and concrete. The two marine towers, which travel alongside the original elevator, fill the new storage in the same manner as they filled the first unit. The longitudinal conveyers receiving from the marine towers run the entire length of the two units. Grain for shipment from the new portion is conveyed through the basement of the first storage to the car-shipping house.

All machinery is electrically driven, power being generated in a steam plant built in connection with the original elevator.



View of Grain Elevator at Port McNicoll.

The work of the John S. Metcalf Company, Limited, for the Canadian Pacific Railway at this point includes: Two travelling marine towers, capacity 20,000 bushels per hour each; a 4,000,000 bushels fireproof storage; one car-shipping house, 200 cars in 10 hours; a 1,500 h.p. power plant; about 1⅓ miles of wharves; a flour shed, 700 feet long; a freight shed, 700 feet long; customs house; carpenter shop; coal platform; sleeping house for freight porters; eating house for freight porters; pump house; water system for fire protection and general supply.

For the railroad the work has been under the direction of Mr. J. M. R. Fairbairn, assistant chief engineer, and Mr. C. W. P. Ramsey, engineer of construction.

ELECTRIC STEEL REFINING.

A paper read by Dr. Paul Heroult at the recent International Congress of Applied Chemistry, at New York, pointed out that the electric steel furnace has now reached a point when the reduction of costs depends entirely on improvements in detail, both in furnace construction and manipulation. In Europe the process was developed more for the high-priced steels, but in the United States the principal problem has been that of making rails. At the present time the application of the electric furnace for the manufacture of intermediate steel and all qualities of alloy and special steels is established. By the use of the electric furnace the quantity of blowholes and waste can be reduced to a minimum, and saving in the cost of machine work alone would justify paying a very much higher price for electric steel castings, if this were necessary. In the case of many low-carbon high-quality castings made in the electric furnace, it is unnecessary to anneal them, which makes an additional saving in the cost of manufacture. The following tests were given for ordinary mild-steel castings from an electric furnace:—

Test No.	Mn. area. Sq. in.	Reduction of area. Per cent.	Elastic limit per sq. in. Lbs.	Ultimate strength per sq. in. Lbs.	Elongation, Dia. ½ in.
36,138	0.2454	39.5	45,696	71,456	3-in.—28.75%
36,139	0.2359	53.2	33,376	63,616	3-in.—35.00%
					2-in.—34.00%

Analysis.—Carbon 0.12%. Mn. 0.40%. Si. 0.20%. Sulphur and phosphorus below 0.02%.

From these figures it will be seen that it is possible to make a mild-steel casting comparing favorably with plate steel.

Another application of the electric furnace which is of great importance to manufacturers of alloy steel depends upon the fact that any quality of scrap can be worked up and the valuable metals retained. Thus, for example: It is not common in practice to melt up charges of miscellaneous tungsten steel including various tools, turnings, hammer scale and "spillings" from crucibles, all of which contain a certain quality of tungsten. Such a charge can be melted up and the necessary additions made to bring the composition up to the required specification. Chrome, nickel, and vanadium steels for automobile work may also be made in this way in the electric furnace by melting up miscellaneous scrap.

Two years ago it was considered good practice to melt and refine steel scrap in six hours at a power consumption of 750-kw.-hours per ton, whereas at present furnaces are working steadily carrying out the same operation in four hours at a power consumption of under 600-kw.-hours over periods of six months. Similar reductions in operating expenses have been made in all other details.

In this issue will be found the index to *The Canadian Engineer* for the past six months. Attention is drawn to this.

ESSENTIALS OF MACADAM ROAD MAINTENANCE.

W. Huber, B.Sc.

Eternal vigilance is the price of a good permanent macadam road. No matter how much care may be exercised in building it, no matter what the quality of the material used, it can be considered at best but a temporary solution of the good roads problem if at the time of building or immediately thereafter proper provision is not made for its systematic maintenance.

The proper and most economical time to commence the maintenance of this class of road is the day it is opened to traffic. No stone used on road construction is absolutely homogeneous, no bottom is absolutely uniform in its bearing power, and, therefore, no two consecutive sections of road can be considered to have absolutely the same strength. Curious as it may seem, ordinary traffic will sometimes show up small weak spots in a road bottom over which the roller passed showing no indication of their existence, the result of which will probably be a small rut—a rut, perhaps, too small to inconvenience traffic or even to be noticeable to a person driving over it, yet large enough to collect water and soften the surrounding roadway.

Assuming that the road has been properly constructed, i.e., with well compacted sub-grade, properly under-drained, the drains running to free outlets, side-ditches carefully constructed, the road properly crowned and the metal properly bound, the idea of maintenance is to maintain these ideal conditions. As the stability of the new road is in so large a measure influenced by the facilities for drainage supplied, so will the durability of the road depend largely upon the care with which these drainage facilities are maintained. The principal work of the man on maintenance will, therefore, be to keep the drainage both above and under the road as perfect as when it was first constructed. This includes keeping the road well crowned, the sides clean and sloping to the ditches, the side-ditches open and their outlets free, drain and culvert openings clean, and ruts and depressions filled immediately they become noticeable.

The amount of work required in such maintenance will depend, of course, on several factors—quality of material used in construction, nature and amount of traffic, nature of soil, grades, climate, weather, etc.

The system of maintenance should be as simple as possible and not more than two men should be concerned in the work of any one section, viz., the road superintendent and the man actually engaged in the work. Regarding the latter, it is true, as in many other cases, that it pays to have a first-class man, even at a rate of pay higher than paid to one of mediocre ability. He must be a man who can understand the principles on which roads are built for permanency, and who can reason for himself. A man at this work will often be working for days at a time without direct supervision, and he must be a man who can be trusted to do his work and who can also be trusted to find work for himself. A man of this description will save the road superintendent many gray hairs, and will leave him time to devote to his heavier problems.

The equipment required for road maintenance other than complete re-surfacing is simple—a pick, a shovel, a wheelbarrow, a fairly heavy tamping-iron, and a pail being all that is required. There should also be deposited at short intervals on the road-side, small piles of crushed stone and grit. For small repairs the stone may be somewhat finer than the regulation two-inch size used in construction. From one to one and a half-inch will be found most satisfactory. The grit for repair work should be selected for its cementing quality, even more than in construction work. For this work it will be found profitable to secure and store a car of the very best grit obtainable, even at a higher price and freight rate than ordinary grit.

The length of road which one man can properly look after varies with local conditions, but ordinarily a single man can keep from four to six miles in good repair. If it is found that he cannot keep up with the work, his section should be shortened, rather than another man added, as it is found the most economical work is done by men working singly.

The best time for examining the entire length of a section is just after a rain. This will show up all ruts and other depressions, and also any obstructions or lack of grade in side ditches, drains and culverts.

The best method for filling ruts and low spots in the surface is to pick the stone loose in and for several inches around the depression, add a little fresh stone and grit, wet it, and tamp thoroughly. It may be found that traffic will disarrange the stone somewhat, but if it is gone over a few times at intervals of a day or so it will be found to have set and become an integral part of the road, and, if the work has been carefully done, indistinguishable from the remainder of the road. These small depressions should be remedied as soon as they appear, remembering that each one forms a basin for the collection and retention of water which in turn softens the road. This work all resolves itself into an attempt to keep the surface drainage perfect.

Another cause of trouble in macadam roads is the allowing of the earth sides to become cut up and become higher than the edge of the stone, thus impounding water that would otherwise run off. These earth shoulders should be kept trimmed below the level of the stone. In this connection an occasional trip over the road with a split-log or plank drag will be found economical. This will necessitate the hiring of a team for an occasional day, but the expenditure will be well justified, and it will be found that the longer this practice is continued, the less dragging will be required, as the surface of the earth shoulder will become hard, smooth and impervious to water and able to support traffic almost as well as the stone section. In fact, this part of the road, where this method has been followed, is in dry weather often preferable for driving to the macadam section.

The remaining most important part of the maintenance man's work is the keeping of all ditches and drain and culvert outlets open. This work will be heaviest in the spring and fall, when ditches tend to become clogged with leaves and other debris. During the winter special pains must be taken to keep all these water-courses in first-class working order, bearing in mind that the principal idea in winter is to have a course ready for the water as soon as the snow starts to melt. In this as in other work it is easier and cheaper to anticipate trouble than to remedy it after it occurs.

These few points, then, comprise what seem to be the essential features in Macdam Road Maintenance, and if they can be put any more briefly, may be stated as follows:

Start maintenance as soon as the road is built.

Put a good man at the work.

Keep both stone and earth sections smooth and properly crowned.

Remove every obstruction to water running off and from under the road both in summer and winter.

And, lastly, and most important of all—keep eternally at it.

WINNIPEG BUILDERS' EXCHANGE

At the annual meeting of the Winnipeg Builders' Exchange, the financial report of the secretary, Mr. A. M. Rose, showed the exchange to be in flourishing condition. The election of officers resulted in the re-election of Mr. W. J. Davidson as president; Mr. F. Hinds, 1st vice-president; Mr. J. McQuarrie, 2nd vice-president; Mr. Thomas D. Robinson, treasurer; and the following to the board of directors: Messrs. W. P. Alsip, J. W. Morley, H. C. McMartin, and R. W. Paterson. The board is composed of twelve members, four retiring each year.

OIL FOR MACADAM ROADS.

Automobile traffic has revolutionized our ideas of permanent road construction. Whereas a dozen years ago a well-constructed waterbound macadam road was considered about as permanent a road as could be desired for country traffic; with the constantly increasing use of the high-speed rubber-tired automobile, such roads have in many cases disintegrated faster than they could be maintained.

It has been clearly demonstrated that the bond in ordinary macadam road is insufficient to protect it against the somewhat complex action of the automobile tire travelling at high speed. The dust raised by this class of vehicles is blown entirely off the road and a fresh lot of dust raised; this repeated action resulting in the wearing down of the road surface, in some cases several inches in a single season.

While oiling a road is not considered a permanent remedy for this disintegration, it serves to keep the dust down, thus preventing the next lot of dust being raised, and by this means temporarily preserving the road. There are many varieties of oil on the market for this purpose, some of which are little better than water, while others, having a bituminous base, on the evaporation of the volatile constituents, leave a certain amount of bitumen to act as an aid to the binder in the road. This bituminous residue is increased at each successive application, so that as time passes the applications may be made fewer and lighter.

The cost per year of applying oil at current prices, amounts to from eight to fifteen per cent. of the original cost of the road if built by day labor, or from five to ten per cent. if built by contract. This expenditure will be well repaid in the elimination of the dust nuisance and the decreased cost of maintenance, as well as in the increased life of the road.

Cost, per application, of oiling one mile of road, of different widths with varying quantities of material.

Oil, 7½ cents per gallon.

Cost of application, $25 00 per mile.

Width of Road	Square yards per mile	¼ gallon per square yard	½ gallon per square yard	¾ gallon per square yard	1 gallon per square yard	1¼ gallons per square yard
10ft	5,867	$135	$245	$355	$465	$ 575
12	7,040	157	289	421	553	685
14	8,213	179	333	487	641	795
16	9 387	201	377	554	729	905
18	10,560	223	421	619	817	1,015
20	11,733	235	465	685	905	1,125

Oil, 8½ cents per gallon.

Cost of application, $25 00 per mile

Width of Road	Square yards per mile	¼ gallon per square yard	½ gallon per square yard	¾ gallon per square yard	1 gallon per square yard	1¼ gallons per square yard
10ft.	5,867	$150	$275	$400	$525	$ 650
12	7,040	175	325	475	625	775
14	8,213	200	375	550	725	900
16	9,387	225	425	625	825	1,025
18	10,560	250	475	700	925	1,150
20	11,733	275	525	775	1,025	1,275

Ordinarily the following applications will suffice:—

First Year—First application, ½ gallon per square yard.
Second application, ¼ gallon per square yard.

Subsequent Years—Two applications, each ¼ gallon per square yard

LUBRICATION OF STREET RAILWAY RAILS.

Water lubrication of street railway rails has been in use for some time on a street in Rome, Italy, carrying heavy traffic. The street is on steep grade and has numerous curves. At the top of the slope a stream of water is fed into each of the four rails of the double track line and flows downhill along the groove of the rail. Every 20 to 30 inches a small wooden block is wedged in the groove, reaching up to wheel flange level, to break the flow of the water. It is reported that cars ride very smoothly on this lubricated track and the grinding noise of cars rounding curves is practically eliminated, while also the general noise of the car traffic is reduced. Grease lubrication at curves is rendered unnecessary.

SMALL WATER POWER WANTED.

A subscriber would like full particulars, with price, of small water powers of about 2,000 horse-power. A firm of carbide manufacturers desires this information. Those interested are invited to correspond with the managing director of The Canadian Engineer.

The Canadian Northern Railway have just signed contracts with builders of rolling stock all over Canada for seven million dollars worth of railway equipment to be delivered during 1913. This will include 130 locomotives, 76 passenger coaches, 300 box cars and variety of other cars. Equipment bonds will be issued for the purpose.

COSTS OF MACADAM ROADS OF DIFFERENT THICKNESSES.

Cost of building one mile of Waterbound Macadam Road of various widths and depths. Comparison of Day Labor and Contract Figures

Day Labor prices based on the following data:
Cost of labor, 20c. per hour.
Cost of teams, 50c. per hour.
Cost of stone, $1.30 per ton, F. O. B., $1.69 per cubic yard.
Weight of 1 cubic yard of Stone, 2,600 lbs.
Average wagon haul, 1 mile. For longer hauls add 25c. per cubic yard a mile.
Total cost in each case includes grading and shaping of road bottom.

WATERPROOF CONCRETE.

Some experiments on impervious concrete were made at Husum, Germany, recently in connection with preparations for the construction of a new lighthouse. Various mixtures of cement and fine dune sand in ratios 1:1 up to 1:6 and mixtures of 1:3 with the addition of various waterproofing material such as soft soap, oil and patented mixtures were prepared and were molded into pot-shaped vessels about 15 inches high, with 2½-inch walls. When these pots had set, some of them were filled with water, others (empty) were set into water; and the density of the walls was judged by noting the time required to empty or fill, the water acting under a maximum head of about 10 inches. The experiments showed that a satisfactory degree of imperviousness was not reached, since in every test the vessels filled or emptied within an hour. The relative success of the richer mixtures then induced tests of rich rubbed surfacing. To this end the surfaces were first wet, then thickly coated with cement paste, and with a soft brush the cement paste was then rubbed into the surface of the concrete. Repeating this procedure several times until the pores were closed, a very satisfactory imperviousness was reached, the pressure tests (as above) continued for three days showing no water passing through the walls of the pots. On the basis of these tests it was decided to build the lighthouse substructure of a 1:3 mixture with surface made impervious by the grout-rubbing process as used in the experiments.

EARTH AND GRAVEL ROADS.*

By Robert C. Terrell.†

Earth roads must be well drained and properly crowned, in order to be serviceable at all times. The maintenance of a road thus constructed is comparatively easy and not very expensive if the work is done at the proper time, but good drainage is very costly, if not altogether impossible, unless the road is properly located. A road, in order to be properly drained, must have the proper longitudinal grade; a minimum grade of ½ of 1 per cent., with a maximum grade, generally, of 5 per cent. The minimum grade is necessary in order to give the side ditches the proper amount of fall to carry the water quickly away from the road. Side ditches should never be made deep and narrow. If extra drainage is necessary, roads should be undertaken by use of tile or by excavating a deep ditch and filling with large stones. Where roads are located along side hills a ditch should be dug on the upper side sufficient to take all the water coming down the hill. Where the grade exceeds 5 per cent., the ditch should be paved with stone and the water should be carried under the road from the upper side at short intervals and disposed of.

If the road has been properly located and properly drained, the point of most importance is the crown; the parabola form is the best, having a centre elevation equal to 1/24 of the width of the road. Frequent causes of mudholes are the unevenness in the texture of the soil and the combining of vegetable matter with the soil while working the roads; this vegetable matter holds water, thus damaging the surface. In no case should stone be piled into a mudhole, as it only forms a rough and unsatisfactory surface and permits the formation of mudholes at either end from the impact of loaded vehicles. The road, however, can be successfully repaired by the removing of the softer soils, or soils containing vegetable matters, and replacing with clay, or soil of the same consistency as the remaining portions of the road, and by removing the shade, so that the sun may have free access to that portion of the road.

Earth roads should have their principal working in the spring of the year when the soils will work most readily and will have time to become consolidated before the fall rains begin. A scraping-grader drawn by a traction engine will do excellent work in giving a road sufficient crown. The earth removed from side ditches should not be thrown into the centre of the road.

In the construction of the gravel road, beginning with the sub-grade, it is probably best to open the trench to receive the gravel, giving it the same crown or cross section as the finished roadbed should have, which should be a parabola, with the centre height equal to 1/40 of the width of the road. Gravels containing clay or sand, or even loam, not exceeding 20 per cent. of the entire quantity, make excellent road material and will bind or compact very readily. After the gravel has been properly placed on the sub-grade it should be thoroughly sprinkled and rolled. In western Kentucky gravel roads cost approximately $1,000 per mile. In eastern Kentucky the cost is slightly higher.

In my opinion the maintenance of earth and gravel roads will never be effectively accomplished until we receive government aid for all post roads and until every road becomes a post road. I do not mean, however, by "government aid" that the government shall bear the entire or major portion of the expense of constructing and maintaining roads, but that the government will merely assist in the construction and maintenance of roads to such an extent as will enable the government to direct the local authorities how the work must be done before the federal aid is available, and then that these roads be put under direct government inspection by making each and every rural mail carrier the inspector of his route, reporting deficiencies in the road as they occur to the local authorities and to make reports to the federal government once each month as to the condition of the road.

* Abstract of paper delivered to American Road Builders' Association, at Cincinnati, December 3 to 5, 1912.

† Commissioner, State Department of Public Roads, Kentucky.

CANADA IMPORTS MUCH CLAY.

Canada's clay imports are classified by the department of customs under three main subdivisions: clays, brick and tile, and earthenware and chinaware, and their total value is shown as $5,156,544, or 62 per cent. of the domestic production, in the annual report of Mr. J. McLeish, B.A., chief of the division of mineral resources and statistics. The imports of clays in 1911 were valued at $270,247, and included chiefly china clay and fire clay, with a small quantity of pipe clay, and others clays not classified. The value of china clay imports was $125,768, and of fire clay, $125,199.

The imports of these clays have varied considerably from year to year, and do not show the same general increase as do the imports of manufactured clays. The imports classified under brick and tile were valued in 1911 at $2,369,761, of which about 34 per cent. was firebrick, other important items being building brick, sewer pipe, and paving brick.

There was also an importation under this class of manufactures of clay not specifically designated, valued at $523,998. The imports of these "unclassified" brick and tile have increased steadily year by year, the value of such imports in 1905 having been only $20,804. The total imports of brick and tile in 1910 were valued at $1,755,773, showing an increase in 1911 of about 35 per cent.

The imports of earthenware and chinaware, of which the most important class is tableware, were valued in 1911 at $2,516,536, as against $2,283,116, an increase of about 10 per cent.

There is also a considerable annual importation of "chalk, china or cornwall stone, cliff stone and feldspar, fluorspar, magnesite ground or ungronnd," much of which is no doubt used in connection with the manufacture of clay products.

The value of these imports during 1911 was $147,640; of which $90,119 was from the United States, $54,548 from Great Britain, and $2,973 from other countries. The value of the imports under this item during the calendar year 1910 was $121,959.

There is also an annual importation of "baths, bath tubs, basins, closets, lavatories, urinals, sinks, and laundry tubs of any material," the value of such imports during 1911 being $285,847, as compared with $262,667 during the year 1910.

Imported clay products are derived chiefly from Great Britain, and the United States, although considerable quantities of earthenware, china, and porcelain ware, white granite or ironstoneware, etc., are brought from Germany, France, Austria-Hungary, and Japan.

Of the brick and tile imported, 76.7 per cent. was from the United States and 23.2 per cent. from Great Britain; and only $578 worth from other countries.

Of the earthenware and chinaware, 62 per cent. was imported from Great Britain; 15 per cent. from the United States; 9 per cent. from Germany; 7 per cent. from France, and considerable values also from Japan, Austria-Hungary, and other countries. The crude clays were imported principally from Great Britain and the United States.

COAST TO COAST.

Victoria, B.C.—The water report for the council of this city will be completed within a few days.

Port Arthur, Ont.—The past year has been a season of activity in the municipal engineering department, and the expense account for general work totals $584,027.

Calgary, Alta.—Colon bacilli has been found in certain sections of the water supply on this city and the medical health authorities have issued warnings to the citizens concerning the same.

Hamilton, Ont.—Mr. C. H. Mitchell, of Toronto, and Prof. Hutt, of the Ontario Agricultural College, Guelph, addressed a large gathering in this city recently on the subject "The Beautification of the Mountain Park."

Montreal, P.Q.—The Harbor Commissioners of Montreal have awarded the John S. Metcalf Company, Limited, a contract for a 1,500,000-bushel addition to the Harbor Commissioners' Elevator No. 1 at Montreal. It will be of reinforced concrete and steel and will cost approximately $700,000. This will make the capacity of Elevator No. 1, 2,500,000 bushels, as compared with 2,000,000 bushels' capacity in the new Elevator No. 2 recently completed by the John S. Metcalf Company.

Eastern Central Canada.—Col. Greenwood, assistant chief engineer of construction on the Canadian Northern's eastern lines, states that rapid progress is now being made on the company's four large bridges now being constructed between Montreal city and Pembroke, at a total cost of about $1,250,000. They are being built over the rivers Laprairie or Back River, the Mille Iles, and the Ottawa at Shaw Falls, and at Portage du Fort. All the sub-structures of these bridges are of concrete, while the superstructure will be of steel, and which will be placed in position during the coming summer. No. 1, which crosses the Back River near St. Genevieve, has eight spans, and is about 1,400 feet in length, while No. 2 has thirteen spans in all, and strikes the Mille Ile after crossing the upper end of Ile Jesu, which at this point is about one and a half miles wide. The structure at Shaw Falls will be 1,800 feet in length, and that at Portage du Fort some 1,300 feet, so, taking the whole four, they make a series of very formidable structures and will all be on the C.N.R.'s main line from Montreal to the harbor of Prince Rupert.

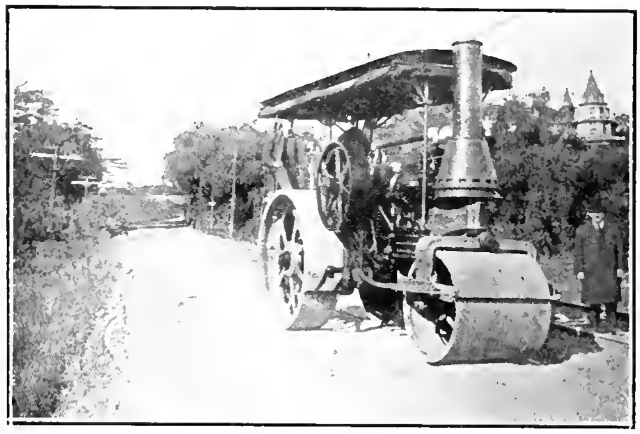
GASOLINE ROAD ROLLERS.*

As far as Ontario is concerned, Gasoline Road Rollers are an inovation in road building machinery.

When making their purchases in 1911, the Commission were recommended to purchase Steam Road Rollers. The Engineer for the Commission took the stand that the steam machines were better known and operators for steam machines could be more easily procured, and, further, that the life of the Gasoline Road Roller was not yet known.

During 1911, and the spring of 1912, all the available information on Gasoline Road Machinery was studied, and when the purchasing of machinery for 1912 was under advisement, Gasoline Machinery was carefully considered, with the result that it was decided to purchase one 12-ton 2-cylinder Gasoline Road Roller.

The advantages claimed by the sales agent for Gasoline Road Rollers are outlined in the catalogue. Amongst them may be found the absence of smoke, sparks, and the risks of boiler explosion. The expense of teams for hauling coal and water is done away with. There is a saving of an hour in the raising of steam and half an hour in closing down. There is some saving through the day, because the engineer has not to fire and take on water. Claim is made by some salesmen that the machinery is much quieter, and not so apt to scare horses on the highway and the grade, as a steam roller; but we might say that in our short experience we do not find much gain in this connection.



Double Cylinder Gasoline Roller Working on the Kingston Road.

We have now had two seasons in which to compare the cost of operation of the steam and gasoline machinery, and the following table will give the comparison of cost, as nearly as can be judged, both rollers working under similar conditions:

COST OF OPERATING STEAM ROLLER.

For Ten-hour Rolling.

Fuel—	
Kindling wood	$0.05
Coal, 380 lbs. at $6.85 per ton	1.30
Water—	
600 gallons—Hauling three hours at, per hour, 50c.	1.50
Oil, etc.	0.05
Engineer—	
11½ hours at 30 cents per hour	3.45
	$6.35

Cost of rolling, 63½c. per hour.

For Ten Hours' Spiking and Scarifying.

Fuel—	
Kindling wood	$0.05
Coal, 480 lbs. at $6.85 per ton	1.64
Water—	
800 gallons, hauling	2.00
Oil.	0.05
Engineer—	
11½ hours at 30c.	3.45
	$7.19

Cost of spiking and scarifying, 71 9/10c. per hour.

COST OF OPERATING A GASOLINE ROLLER.

For Ten Hours' Rolling.

Fuel—	
12 gallons of gasoline at 15c. per gallon	$1.80
Water—	
Cooling quarter hour	0.12½
Oil.	0.07
Engineer—	
10¼ hours at 30c.	3.07½
	$5.07

Cost of rolling, 50c. per hour.

* Abstract from 1912 report of the Board of Highway Commissioners, York County, Ontario.

For Ten Hours' Spiking and Scarifying.

Fuel—	
20 gallons of gasoline at 15c. per gallon	$3.00
Water—	
For cooling	0.15
Oil	0.07
Engineer—	
10¼ hours at 30c.	3.07
	$6.29

Cost of spiking per hour, 62 9/10 cents per hour.

The saving which is shown on the work in favor of gasoline has been in its constant operations. We gain from one to two hours a day of actual operations with our gasoline roller.

When we first purchased these machines we were afraid they would be difficult to start in cold weather, but this has not been the case.

The gasoline road roller has not been in operation long enough in Canada for us to be sure of just what it will do, but the success that has accompanied the gasoline engine in other fields of operations would indicate that it could be successfully operated in connection with road roller work.

GRAND TRUNK PACIFIC CONSTRUCTION.

The work accomplished by the Grand Trunk Pacific Railway for the twelve months ended December 20th is contained in the chief engineer's annual report issued in Winnipeg. It shows that construction has been undertaken on 563 miles of main line, and on 688 miles of branch lines, making a total of 1,251 miles of line on which clearing, grading and track-laying have been done. Track has been laid on 128 miles of main line, and on 331 miles of branch lines, making a total of 459 miles of railway completed exclusive of second tracks and sidings.

On the section known as "main line Winnipeg west," grade is now completed to mile 1,124, Rau Shuswap crossing, and track should be laid to that point before the close of the year. The line is in operation from Winnipeg to Tete Jaune Cache, mile 1,095. From the Rau Shuswap crossing at mile 1,124, westerly to mile 1,403 (Endako river crossing), the right of way is being cleared and at those points where clearing has been completed, active grading operations are under way. For instance, the grade from Rau Shuswap crossing to the second crossing of the Fraser river at mile 1,190, should permit of track laying in the space of a month or two.

From Prince Rupert easterly the track is laid to mile 189, being held up at that point, owing to the erection of steel bridges. Eighty-nine miles of this track were laid during 1912, and the line is in operation to Hazelton. From mile 189 to the Endako river crossing (mile 341 Prince Rupert, or mile 1,403 Winnipeg), active grading operations are in progress.

Harte to Brandon—Grading is under way on this branch and although 10.8 miles are ready for track no steel has yet been laid. The total length of this branch is 25 miles. Regina to international boundary, only the last 19 miles of this line require to be graded. The track is laid for 106 miles, and was all put down this season.

Prince Albert Branch—This line extends from Young on the main line, and is in operation from that point to Wakaw, a distance of 67 miles. No track was laid in 1912. A large steel bridge has yet to be erected over the South Saskatchewan river, but with the exception of the entrance into Prince Albert the grade is practically completed.

Tofield to Calgary—This line is 202 miles long. A few steel bridges have yet to be erected but grading is almost completed. During 1912 steel was laid from mile 07 to mile 165.3, and the track will be continued to Calgary in the early spring of 1913. The line is in operation to mile 62.

Other branch lines reported upon are the Talmage-Weyburn line, 15 miles in length, of which 39 per cent. of the grade is completed; and the Regina-Moose Jaw connection, of 49 miles, which is now completed, and its terminals at Moose Jaw in course of construction. Grading is completed on Moose Jaw-Northwest branch, but no steel has been laid. All the track on the Oban-Battleford branch was laid during 1912, and the line, 48.5 miles in length, is now completed. The Cut Knife branch from Battleford westerly toward Wainwright is finished, so far as grading is concerned, and four miles of track are laid. Steel will be laid throughout its length in the early spring of 1913. A branch line is surveyed from Biggar to Calgary, and it is stated by the chief engineer that for the present time this line is only being constructed as far as the Saskatchewan-Alberta boundary, a distance of 104 miles from Biggar. Grading on this portion was completed in 1912, and steel is laid to mile 37. The Alberta coal branch, which extends 56 miles southerly from Bickerdike on the main line, is graded for the whole of its present length.

PERSONAL.

FRANK BARBER, consulting engineer, Toronto, has quite recovered from his recent illness, and is able to look after all his work.

O. H. HOOVER, B.A.Sc., is at present located at Moose Jaw, Sask. He has taken charge of the hydrographic work in the Moose Jaw district for the present winter.

W. K. TASKER, formerly superintendent of the Pere Marquette R.R., at Saginaw, Mich., has been made superintendent of the Canadian division with headquarters at St. Thomas, Ont.

F. A. CREIGHTON, who has been city engineer of Prince Albert, Sask., since July, 1907, tendered his resignation at the final meeting of the city council. It is probable that he will locate in private practice in Winnipeg.

PHILIP P. SHARPLES, chief chemist, Barrett Manufacturing Company, Boston, on December 30th delivered an illustrated lecture on the "Manufacture of Refined Coal Tar," before the graduate students in Highway Engineering at Columbia University.

N. H. MANNING, a graduate of the Faculty of Applied Science and Engineering, of the University of Toronto of the class of '09, is the Toronto district representative of the Canadian Inspection and Testing Laboratories, Limited, 25-27 Manning Arcade Annex.

J. W. EBER has been appointed to the position of general manager of the Toronto, Hamilton and Buffalo Railway Company. Mr. Eber was formerly general superintendent for the same company; that position is now abolished. His headquarters will be Hamilton, Ont.

JAMES B. GOODWIN, recently superintendent of construction and assistant general manager of the Mount Hood Railway and Power Company, Portland, Ore., has been appointed construction engineer for the city of Edmonton, Alberta. Edmonton proposes to do a large amount of new work in the coming year.

LIEUT.-COL. WILLIAM PATRICK ANDERSON, of the Dominion Department of Marine and Fisheries, who has just been honored by King George with a C.M.G., was born at Levis, Quebec, in 1851. He was one of the charter mem-

bers and subsequently president of the Canadian Society of Civil Engineers. He was the founder of The Canada Militia Gazette, and has had a long and distinguished military service. For many years he was member and chairman of the Ottawa School Board.

OBITUARY.

MR. JOHN J. McDONALD, a former assistant engineer of Medicine Hat, Alberta, died recently in that municipality. He was 32 years of age and came to Western Canada about six years ago, and has held several important civic and government engineering positions. His home is in Glace Bay, N.S. Heart failure is given as the cause of death.

COMING MEETINGS.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual Meeting will be held on Jan. 28th, 29th, and 30th, 1913, at the Society's new headquarters, 176 Mansfield St., Montreal. Secretary, C. H. McLeod.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE. Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase, Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

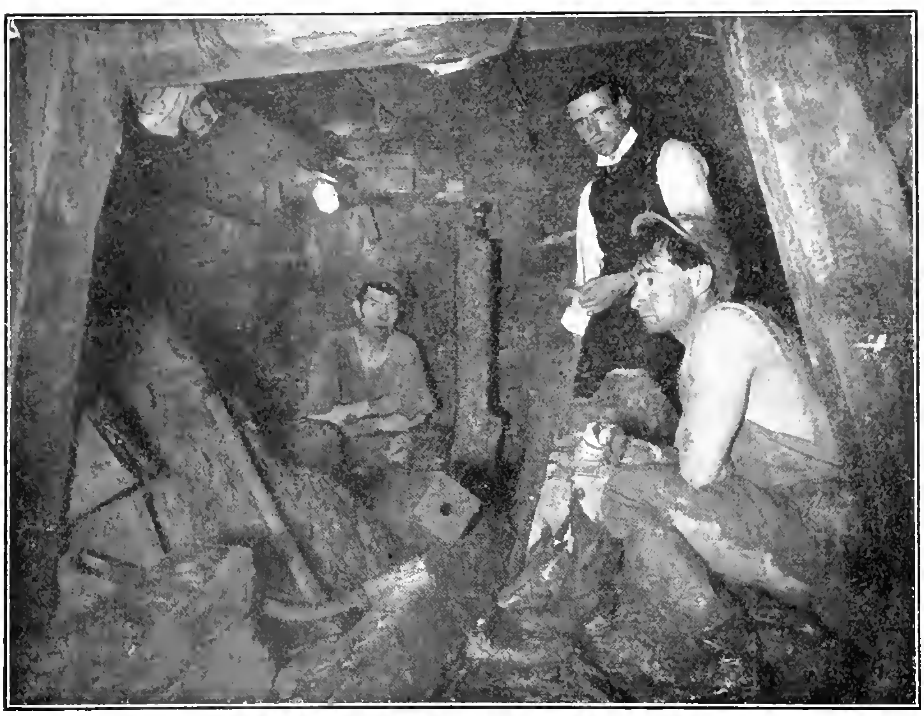
CONSTRUCTION OF A CONCRETE SEWER TUNNEL THROUGH DIFFICULT GROUND.

By H. S. PHILIPS, Resident Engineer.

The sewer described in this article, and known as Barton Section 1, forms part of a system of storm overflow sewers provided to relieve the congestion of the existing sewers in the western section of the city of Toronto, known as the Garrison Creek drainage area.

The existing sewer for which relief is provided by this storm sewer is that running along Bloor Street easterly from the Garrison Creek (at Willowvale Park) to Huron Street. Floodings were experienced in cellars of houses and stores during heavy rains, and in view of the immediate addition of the northern districts, the necessity for relief became more urgent.

The general scheme of existing drainage of the area in question is that of tributary sewers extending from south to north, with main sewers running east and west. These main sewers discharge into the Garrison Creek, which runs practically north and south, discharging into the lake at the south end.



Heading at Station 28 + 00, Abandoned at Station 28 + 28.

The question of paralleling, in order to relieve Bloor Street Sewer, was considered out of the question on account of the busy nature of the street, and the presence of the street railway tracks. Other utilities underground were numerous and formed obstructions. The geological formation was found to be bad for sewer construction in tunnel, involving running sand, clay and water pockets, boulders, etc. The idea of open cutting could not be entertained owing to the obstructions and street traffic. On these accounts it was decided to place the sewer on Barton and Lowther Avenues, to the north, although the subsoil, as indicated by borings, was equally bad, being of glacial deposit formation, as in Bloor Street, but the streets were not so hampered with excessive traffic, and in the event of open cutting having to be resorted to, would inconvenience little.

The total area drained by the Barton Avenue sewer is 701 acres, and extends some 670 feet north of the C.P.R. northern line. The whole area has a fall from north to south and is practically level from east to west.

The existing sewers and those new sewers required for future drainage run along the north and south streets, discharging into Bloor Street at the south end. The system is the "combined."

The method of interception is that of tumbledown shafts, as shown in Fig. 2, with tumbledown C. I. pipe shoots for the smaller sewers and the sanitary flow of the larger ones. The whole flow, sanitary and storm, is intercepted and carried in the storm sewer. Separation of the sanitary and storm water is provided for at Bloor Street on the Garrison Creek sewer. The channel provided for the sanitary flow in the storm sewer is shown in Fig. 2.

The total length, including section 2, is 7,741 feet; section 1, to which this article refers, is 3,345 feet long and is at the outlet end of the sewer.

Fig. 2 shows the typical cross section of the sewer as carried out. The flat section was designed to same height across the low-lying land of Willowvale Park, so that mounding would not be necessary. The remaining sections gradually increasing in size towards the outlet, are designed for tunneling so that the invert can be placed, as conditions per-

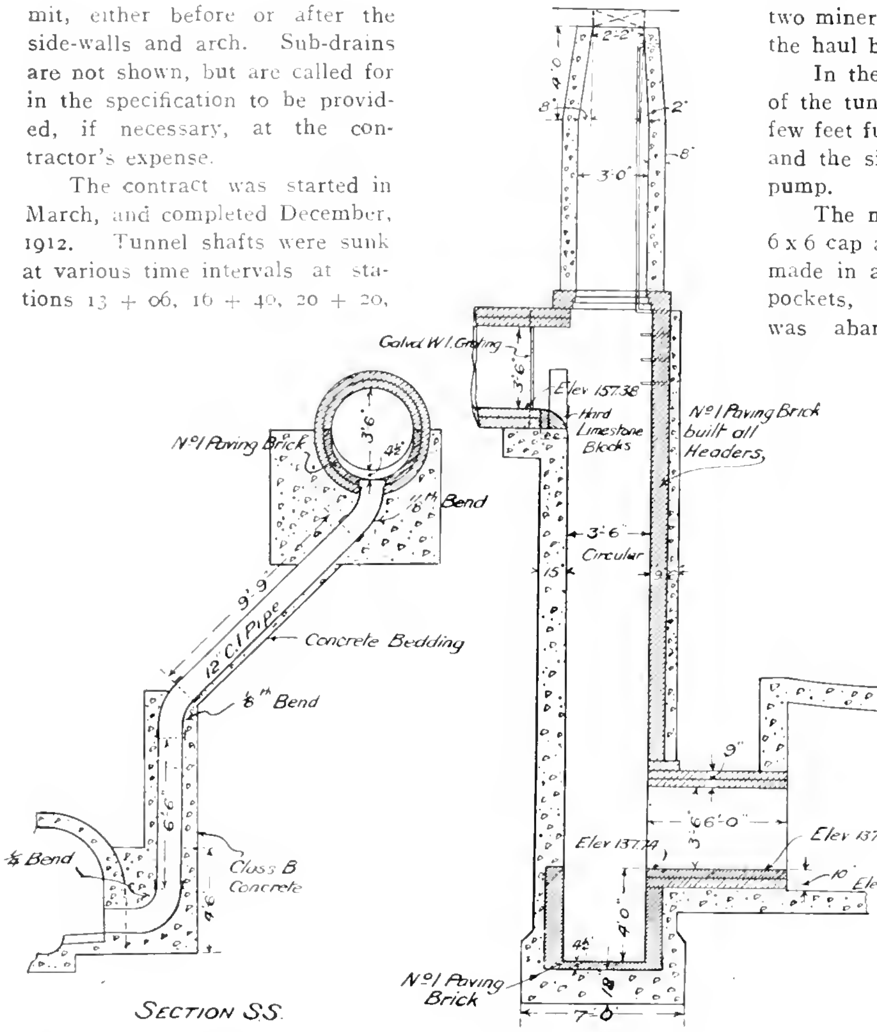
mit, either before or after the side-walls and arch. Sub-drains are not shown, but are called for in the specification to be provided, if necessary, at the contractor's expense.

The contract was started in March, and completed December, 1912. Tunnel shafts were sunk at various time intervals at stations 13 + 06, 16 + 40, 20 + 20, 23 + 06, 26 + 00 and 31 + 20, numbered respectively 6, 5, 4, 3, 2 and 1, and headings were driven east and west from all shafts. The depths of the shafts are as follows: No. 1, 34 feet; No. 2, 35 feet; No. 3, 35 feet; No. 4, 37 feet; No. 5, 35 feet; No. 6, 31 feet deep. The shafts for manhole and tumbledown shafts at Christie Street were 33 and 44 feet deep respectively. The open cut part has a varying cover from two to eight feet.

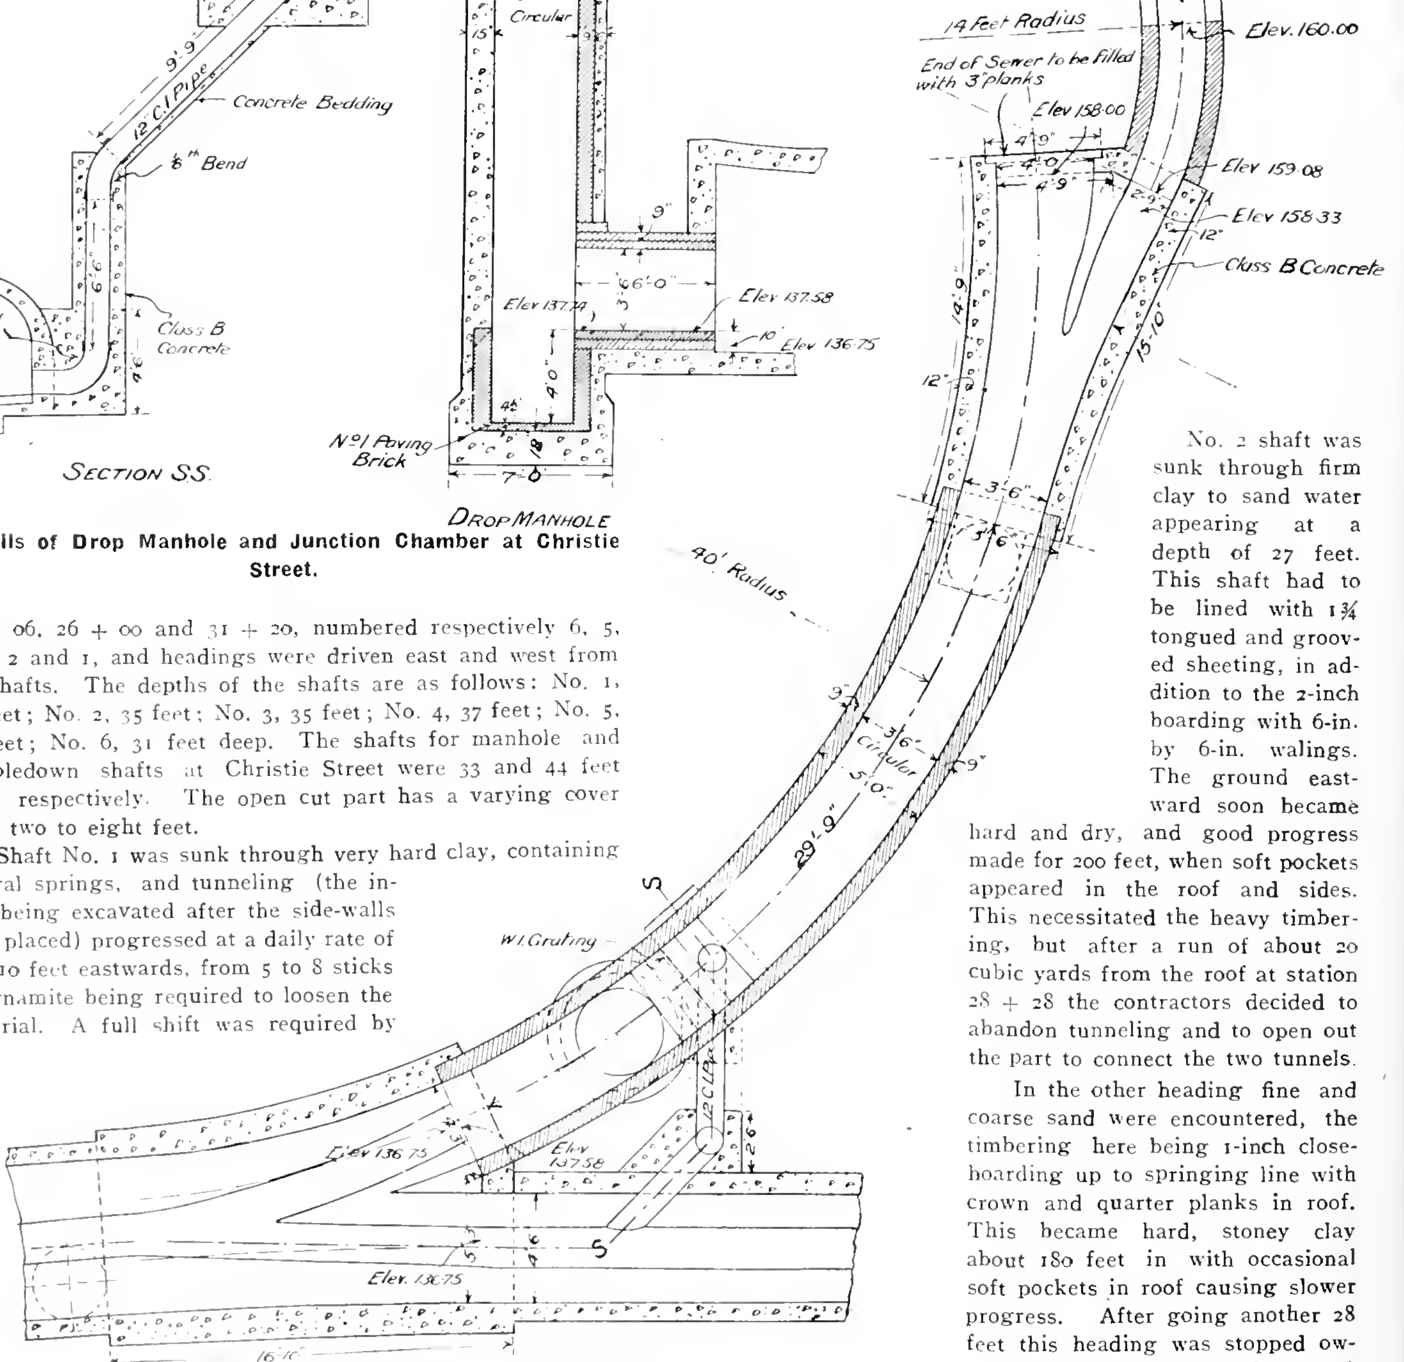
Shaft No. 1 was sunk through very hard clay, containing several springs, and tunneling (the invert being excavated after the side-walls were placed) progressed at a daily rate of 8 to 10 feet eastwards, from 5 to 8 sticks of dynamite being required to loosen the material. A full shift was required by two miners and one mucker—two muckers being required as the haul became longer.

In the other direction quicksand appeared in the bottom of the tunnel about 150 feet in, and rose above the crown a few feet further on. Water became troublesome at this point and the siphon in the shaft had to be replaced by a 4-inch pump.

The method of excavating was now altered, and with 6 x 6 cap and by timbering an advance of only four feet was made in a double shift. After several runs of semi-liquid pockets, extending almost to the surface, the heading was abandoned and bulkheaded at station 29 + 62.



Details of Drop Manhole and Junction Chamber at Christie Street.



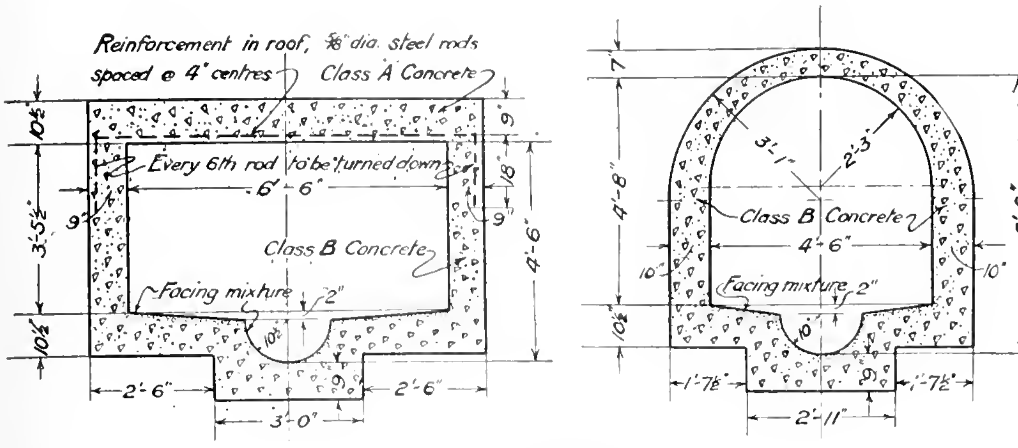
Junction Chamber at Christie Street.

No. 2 shaft was sunk through firm clay to sand water appearing at a depth of 27 feet. This shaft had to be lined with 1¾ tongued and grooved sheeting, in addition to the 2-inch boarding with 6-in. by 6-in. walings. The ground eastward soon became hard and dry, and good progress made for 200 feet, when soft pockets appeared in the roof and sides. This necessitated the heavy timbering, but after a run of about 20 cubic yards from the roof at station 28 + 28 the contractors decided to abandon tunneling and to open out the part to connect the two tunnels.

In the other heading fine and coarse sand were encountered, the timbering here being 1-inch close-boarding up to springing line with crown and quarter planks in roof. This became hard, stoney clay about 180 feet in with occasional soft pockets in roof causing slower progress. After going another 28 feet this heading was stopped owing to grade going with the tunnel

and the sub-drain not being able to carry off the water.

The most expensive shaft to sink was No. 3, quicksand being found 15 feet below the surface, requiring tongued and grooved sheeting, in addition to two inner sets, the ground becoming very hard clay two feet above the crown. To meet the tunnel from No. 2 shaft only 86 feet were necessary and only 14 feet were excavated westward before meeting



Typical Sections.

From Station 0 + 00 to 6 + 15. From Station 6 + 32 to 26 + 12.

from shaft No. 4, the soft pockets appearing in the roof, while up to springing line the clay was exceedingly hard, but was not blasted on account of disturbing the caps and lagging or causing a cave-in of the roof.

Progress from shafts 4, 5 and 6 was made at an average rate of 10 to 14 feet per shift in firm clay.

The shallow section in the park was completed during hot weather across the bed of the old Garrison Creek, water bearing sand being met with for 250 feet from the end. The invert was laid immediately after excavation, the walls then being built in the dry. At the foot of the slope (Sta. 5 + 40) tunneling was started to meet the one from shaft 6. The ground was dry sand and was timbered with cap and legging as far as the flat-topped section extended. This was left unlined until the headings met and were lined in order to have headroom.

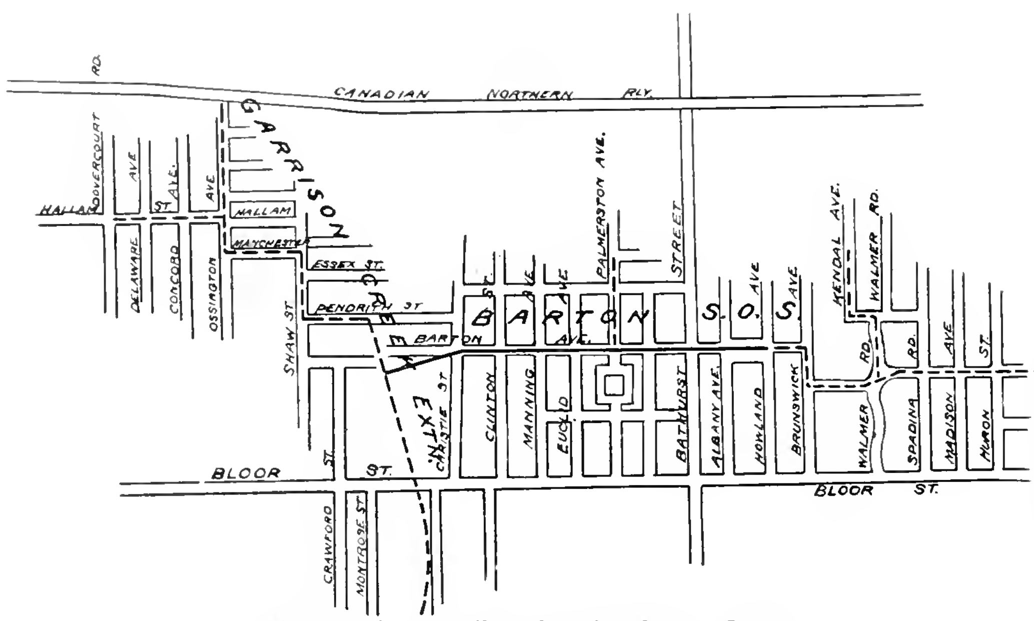
For about 300 feet the arch section only required crown and quarter planks in a 12-ft. length. At this point the ground became clayey with soft pockets in roof, and gave trouble for about 90 feet. In the portion between the abandoned headings the contractor sunk a shaft midway and essayed tunneling both ways. On finding quicksand at a height of 10 feet above the invert, they gave up the attempt, and opened 70 of the 134 feet to be done. Two sets of timbering and one set of tongued and grooved sheeting were required in excavating to sub-grade. The walls and arch were completed before excavating for invert. In the remaining 30 feet and 34 feet at the ends, the excavation was removed up to the hard ground and the roof lightly timbered. The timbering was braced from 12-in. by 12-in. needles, one end resting on the old concrete and the other on the more recent arch. After concreting the walls and arch, the sheeting was cut off at springing level and the voids at the back filled up. After the concrete had set the needles were removed, the roof being braced directly from the concrete until the back filling was done. Voids in the roof and settlements of backfilling were made good with sand through 12-inch auger holes bored from the surface.

The concrete lining was done each night by a gang supervised by two inspectors. The concrete was hand-mixed and sent down the chute directly into the tunnel cars.

The forms were originally 5-in. by 4-in. built-up lumber ribs with 2-in. by 2-in. dressed laggings. The ribs were set on footblocks and braced at the bottom from the rail ties. The lumber ribs were dispensed with after some time and replaced by 2-in. by 2-in. T iron ribs in one piece, and bent to conform to the arch. These gave 6 inches extra clearance for the cars and where not damaged by the blasting.

The laggings joined up badly and did not leave a good finish, which necessitated the surface being plastered.

In bad ground, where centre posts supported the roof, the posts were concreted round, the holes being filled up when posts were removed. The invert, with sub-channel, was laid in 12-foot lengths, the channel in the rough being formed by 2-in. by 2-in. laggings with half-round blocking pieces braced from the roof. The facing mixture was applied to the channel under drums placed in position as soon as the laggings were removed. At one or two places the wall became undermined while excavating for sub-channel in soft places owing to want of braces, and broke away from the arch. These breaks were repaired after invert was set.



Map Showing Location of Barton Avenue Sewer.

The Garrison Creek extension sewer is still undergoing completion, and to avoid cumbersome by-pass channels, the connections to the intercepted sewers had to be built so that the sewage could take up its old course until the new sewer was entirely in commission.

At Christie Street, the invert of the existing 2-in. by 3-in. egg-shaped sewer, 16 feet below the surface, is diverted into a new junction chamber, which provides a connection for an additional 4-ft. diameter sewer relieving the Christie Street drainage area. A flume at present carries the sewage over the diverted invert into the old sewer, which, when the flume is removed, will be closed by an iron stop plate working in iron grooves. An inspection manhole is built directly over this connection.

Abandoned Heading at Station 29 + 62.

A 3-ft. 6-in. diameter sewer leads from the junction chamber on a 40-ft. rod, curves to the tumbledown shaft, which is lined with vitrified brick. This shaft has a well 4 feet below emptying level, which flows directly into a chamber at tunnel level. The sanitary flow enters the tunnel as before described by a C.I. pipe. These were constructed as far as possible in the tunnel shafts.

The work was done under Mr. W. R. Worthington, assistant engineer for sewers by Messrs. Lehman, Graham and Jeron.

ZOELLY STEAM TURBINES.

Low steam velocity, as well as the simplicity of design, which are the main features of the Zoelly steam turbine (manufactured by Escher Wyss & Company and a number of licensees) have not only made this turbine type very economical regarding low steam consumption, but have also the effect that the high economy is maintained practically for any time of running.

Below we give the test results on two Zoelly turbines supplied by Escher Wyss & Company to the Dusseldorfer Rohren Industrie A. G., Germany. These turbines were installed in August, 1910, and have since been running continuously. The main data are as follows:—

Output .... 1,500 h.p.
Speed .... 3,000 r.p.m.
Gauge pressure .... 170 lbs. per sq. inch.
Superheat .... 662 deg. Fahr.
Vacuum .... 90 per cent.

Each turbine is fitted with surface condenser with rotary air and centrifugal cooling water pump, the cooling water being recooled in a cooling tower. After three months running the first tests were made (November 1st, 1910); after a further run of 13 months, each turbine being run for 4,000 hours and having generated 450,000 kw. hours, the second tests were made (December 27th, 1911); no inspection or cleaning was done before the test. The results of these two tests are tabulated below.

The second tests were made with the purpose of ascertaining to what extent the steam consumption had increased after one year's run. The results proved that no variation in the steam consumption had taken place, and when, after tests, the turbines were opened, no wear could be found on the nickel steel blading.

The steam consumption figures guaranteed by the manufacturers were easily obtained, and in fact the test figures were several per cent. lower than guaranteed. The last columns of the table below show that the figures obtained after three months' and after 16 months' running are practically equally good when compared with the respective guarantees. When taking into consideration that the vacuum at full load during the test was 92.1 per cent., and the superheat 580 deg. Fahr., the steam consumption of 15.15 lbs. per kilowatt hour is very good.

Test results on Zoelly turbine No. 2, installed at power station of the Dusseldorfer Rohren Industrie A. G., Dusseldorf, supplied by Escher Wyss & Company:

	Nov. 1st, 1910.			Dec. 29th, 1911.		
Duration of test, mins.	70	54	57	61	120	60
Rev. per min.	3000	3000	3000	3000	3054	3036
Output in kw., excluding excitation	277	541	781	1047	1044	547
Efficiency of generator, per cent.	73.6	84.6	88.9	91.0	91.0	84.6
Gauge pressure in front of stop-valve, lbs. per square inch	190	187	182	181.1	170.5	172.4
Superheat, deg. Fahr.	505	540	556	579	480	458
Vacuum in inches (barometer 29.2 in.)	27.94	27.68	27.3	26.9	26.78	27.54
Total steam consumption, lbs. per hour	5840	9620	12820	15880	17320	10510
Steam consumption per kw. hour	21.82	17.40	16.83	15.15	15.52	19.2
Correction for steam temperature (12½ = 1 per cent.) %	—12.4	—9.5	—8.0	—6.9	—14.14	—16.1
Correction for vacuum (1 per cent = 1.5 per cent.)	+3.2	+3.2	+3.2	+3.2	+2.5	+2.5
Total correction in per cent.	—9.2	—6.3	—4.8	—3.7	—11.9	—13.9
Steam consumption per kw. hour at 662 deg. F. and 26.3 in. vac. at full load	20.1	16.58	15.63	14.58	14.58	16.5
Guarantee of manufacturer (without margin)	20.6	17.5	15.74	14.97	14.97	17.06
Better than guarantee (%)	3.7	2.8	.7	2.6	2.6	2.8

An order-in-council has been passed amending the harbor regulations of Canada and prohibiting the discharge or disposal of oil, tar or other dangerously inflammable material in the water of any harbor of the Dominion. The order provides for a fine of $50 for violation of its provisions, with a further penalty of $10 for every twelve hours during which the offence continues.

THE ROAD QUESTION IN MANITOBA.*

By A. McGillivray.†

I have wondered several times if the municipal men who had charge of the construction and improvement of roads during the past year have looked back over the season's work, and could there see something that had been done during the past year which tended to give Manitoba some mileage of good roads; that is, if they could see something that had been done which might be counted as a permanent improvement towards the foundation of building up a system of roads for Manitoba. No doubt many of the municipal men will say that they have, that something has been done; others may be a little doubtful of the matter; but, for myself, when I looked back over the season's work, I cannot say that a great deal has been done towards giving Manitoba a system of good roads. I cannot say that there has been any great construction of mileage, but I will say that a great step has been taken by securing good legislation in this connection. At the last session of the Legislature, legislation was secured by the efforts no doubt of this Association of Rural Municipalities towards this end, and, as you all know, there are at present on the statutes of the Province two Acts which were placed there at the last session. One is known as the Good Roads' Act, which this Convention, in conjunction with the Manitoba Good Roads' Association, has been instrumental in putting into force That Act, as it appears on the statutes to-day is, in my opinion, a workable Act, and one quite applicable to the conditions that exist in the municipalities of this Province. From the amount of correspondence that I have had during the summer from municipal men in regard to these Acts, I believe that there has been, and is still, some confusion and confliction as to the intent and meaning of both these Acts, and in that event I would just like to take a little of your time in explaining the Acts as I interpret them, or as I believe they are intended to be interpreted. The Good Roads' Act, which was put on the statutes last session with the recommendation of this Convention, provides for the improvement of municipal roads, that is, roads in the municipality that will benefit all the municipality as a whole, and not pertain to any special or particular part of the municipality. The idea was to get the municipalities to undertake a system whereby they could start some plan to improve a certain mileage of roads. While it naturally follows that these roads should be the main roads of that municipality—(roads leading from the towns and market places and villages into the country districts, allowing the farmer to haul his grain to and fro, and putting them within reasonable distance of all ratepayers), it is apparent to everybody that such roads could not be constructed to every man's door, but the intentions and the objects should be to construct these roads so as to place them as near as possible, in order that they will benefit the municipality as a whole to the greatest extent.

Now, under that Act the Government provides for the guaranteeing of the bonds of the municipality; that is, if a scheme is drawn up and presented to the Department of Public Works undertaking a plan such as I have mentioned that is and will be a benefit to the whole municipality, then the provisions of the Act provide that of a municipality raises sufficient debentures to cover the cost of the work, the Government will guarantee the bonds, insuring a probably cheaper rate of interest, and also extending the terms of those bonds over a longer period of years than is prescribed in the Municipal Act. The extent of the bond to be raised is 3 per cent. of the total assessed valuation of the municipality. As I said before, the Act is workable and very applicable to the conditions of this Province, and I believe that if the municipalities of this Province would consider that and take it up, a step would be made in the right direction towards securing better roads.

The Highway Improvement Act, which is another Act which has been placed on the statutes, was put there for probably a different purpose, and it is the confliction of these two Acts, I believe, that has caused a great deal of the confusion in the minds of some of the men of the Province. The Highways Improvement Act was intended to construct provincial roads, or a provincial road—that is, to connect the larger centres of population of this Province. For instance, a road from Winnipeg to Portage and Brandon and to the western portion of the Province. Then another might be considered running from Winnipeg to Emerson. The idea was to get the larger centres of population to endeavor to induce the municipalities of this Province to construct a higher class of road than it would probably be necessary for them to construct in the municipal system. The idea is prevalent all over the Dominion of constructing provincial roads. We hear a good deal of a transcontinental road—that is, a road connecting all the Provinces from ocean to ocean. But, aside from that, in the different Provinces at the present time there is an idea to construct these roads and join up the centres of population, the larger towns of the different Provinces, and to build a road of a higher standard than would be necessary in a municipality itself, and probably the municipality would be able to construct another municipal system of their own, which would be taken care of under the Good Roads' Act.

I have no doubt that many of the applications which have come in for municipalities to be placed under this Highway Improvement Act have been done probably from a desire, no doubt, to participate in the Government grant, and the desire, of course, to build up the roads in their several municipalities, and no doubt some disappointment has been met by some of the municipalities in not knowing the true meaning and intent of the Act, and probably being refused to be allowed to come under this Act at the present time. But, Mr. President and gentlemen, in connection with this Act, as I said before, the Good Roads' Act in my opinion is a good Act, good in name as well as in terms, and should be taken up by the different municipalities with the Provincial Government. There are a few recommendations that I have been making to the Government of the Province in regard to both these Acts, which I have the privilege to submit to you this morning, and would ask you to consider them and find out what they are worth. There may be probably other changes that would appear to you to make these Acts more applicable to the conditions here in the Province, but there are a few that I thought would be necessary to the proper working out of the Act, and, as I said before, I have laid them before the Government, and have their permission to lay them before you for your consideration.

In regard to the Good Roads' Act which, as you know, is the Act by which the Government guarantees debentures for the main roads of the municipalities, independent of any provincial scheme or idea that may be in mind, this was passed at the last session of the Legislature. In my mind, it fills all the requirements to insure construction, except that no Government aid is provided, which to a very considerable extent is responsible for its provisions not being more largely availed of by the municipalities. I would suggest amendments as follows: (1) Provision enabling the Government to contribute towards the cost of any work performed under the Act to the extent of, say, 25 per cent. It is for the municipalities to consider whether that is enough or too much. It may be too much; in my mind it is the maximum. In making this suggestion I have given the maximum, and I

*Address delivered before Ninth Annual Convention of Union of Manitoba Municipalities, Winnipeg, Man., Nov. 26—28, 1912.

†Highway Commissioner for the Province of Manitoba.

would further recommend that this sum be provided by Parliament yearly to meet the expenditures for the ensuing year. Secondly: Provision that any work performed and aided under this Act shall be maintained and kept in good repair by interested municipalities to the extent and manner satisfactory to the Highway Commissioner failing which such repairs may be performed by that official and paid for and levied by the Municipal Commissioner against the respective municipalities in default.

There is a word I would like to say on the maintenance question before I go any further. Is there any use of us thinking of building roads in this Province and leaving them to deteriorate from lack of maintenance, we might as well not build them at all. A good road that is built and laid down in this Province requires certain attention to keep it up to the standard at which it was put down. If we neglect to do that we are working a hardship on the taxpayers of this country, because if we build roads by money that is borrowed on terms extending over a long period, say, for twenty-five or thirty years, the burden would fall on the people who are coming afterwards in later years, and who must assume their portion of that taxation; we must give them something for their money. What I mean by maintenance is this: that a grade should not be allowed to deteriorate and disappear, as grades certainly will do if not looked after very carefully. The great percentage of our roads in this Province are earth roads and no matter how well you build the roads to grade or dig the ditches, if you have not proper drainage, if you allow the ditch to become silted up or become defective and left without any care at all, as many of our ditches have been in the past, in five years they will be useless. I know ditches that have been built fifteen or twenty years ago that have been allowed to deteriorate, and to-day they are only a mark in the ground. So it would be wrong, in my opinion, for the municipalities of the Province to borrow money at long terms and to perform work and let it go to rack and ruin. That is what I mean by proper maintenance; preventing the work from deteriorating.

In regard to the suggestion toward the Highway Improvement Act. This Act, I believe, is a commendable one also. We should have in this Province a mileage of roads of a better class than earth roads, if it is possible to at all get them. Other Provinces are striving to get them. We can't get away from the fact the automobile is the mode of locomotion that is going to stay. People are taking to the automobile. There is no better way in which the value of the farm can be observed than in travelling along a good road, and there is no way in which the development and worth of a country can be more lost sight of than in travelling over a bad road. I believe it is up to the old established municipalities to bring into existence what might be called a few provincial roads of gravel or macadam in the not too distant future. It was for this end that this Act was placed on the statutes. The Government are anxious to see this done, and they are willing to contribute largely, so largely, indeed, as to leave themselves open to extend that assistance to two-thirds of the actual cost.

I would suggest under the Highways' Improvement Act, in order to avoid confusion with the provisions of the Good Roads' Act, that it be determined by legislation to what leading highways in the Province, describing the routes, it is intended that the Act should apply, and shall be constructed and aided under it; with the further provision that the Lieutenant-Governor-in-Council shall have power to add to the number of roads from time to time.

I believe that the Government should indicate where they want the municipalities to take up this work, because the Government would not and do not intend to build those provincial roads themselves. They want the co-operation of the municipalities through which those roads are to pass. The Government could advance a plan to certain municipalities of this Province that they would be first in line for this road. It would be then up to them either to come forward and accept their proposition or reject it. We cannot build these highways through every municipality in the Province; it would be out of the question for the country to do so but if the government would come forward and say where they intend these roads should be, the municipalities through which they are going to pass would be in a better position to take up the work. I believe it would be a valuable provision of the Act.

Further, I would suggest that an amendment should be made so as to permit a municipality to assess its portion of the cost of works performed under the provisions of the Act partially over the lands abutting on both sides of said highway or highways. Because, however anxious a municipality might be to participate in the provisions of this Act, they might be defeated in such a project by having to submit a by-law to the whole municipality, whereby they would raise a portion of the cost of the work over that whole municipality. I believe a road of that nature running through any municipality would be a certain benefit to the whole municipality, but it would particularly benefit the land immediately adjoining the road, and I believe that the land that is particularly benefited should be particularly assessed to pay for it.

HEAVY RAILROAD CONSTRUCTION.

By Sir Thomas Shaughnessy, C.V.O.

Notwithstanding the large amount of railway construction in Canada during the past year, there is every indication that quite as much will be required during the coming year. This means a great deal for the country because, besides giving employment to many thousands of men in the making of the railways, it naturally stimulates manufacturing in the rail mill, iron and steel works, lumber mills and a large number of other establishments, and keeps the wheel of national prosperity spinning.

Speaking for our own company, the rail requirements for the next year will approximate 250,000 tons, and these, with the requisite fastenings, will represent an expenditure of over $8,000,000.

During the past year, in addition to keeping our own manufacturing shops occupied to their capacity, we have taken all the cars and locomotives that we could have built in Canada, and have also made large contracts with manufacturers in the United States. At the present time our outstanding orders for cars and locomotives, to be delivered before the end of 1913, aggregate $30,000,000, and a very large proportion of this amount will be spent in Canada.

Then there are the other works, to which reference was made in the annual report. The extension of our double track system East and West, the important terminal works at Montreal, Toronto, Winnipeg and Vancouver, and the large locomotive and car works at Ogden, near Calgary, that will involve the employment of very many men, and the use of a great deal of material.

We fully recognize the transportation necessities and claims of the country and it is our anxious desire to meet them in so far as the obligation rests with our company, but our operations are frequently delayed by conditions that we cannot overcome, such as an unfavorable season and a shortage of men and material.

My own feeling is that, surveying the situation conservatively, the year 1913 will be replete with development, progress and prosperity for Canada.

INSTALLATION OF ROTARY CONVERTERS AT C. P. R. DOCKS, FORT WILLIAM.

The following installation of two 600-kw. Westinghouse rotary converters with necessary accessory equipment of transformers, equalizing generator, etc., was made during the past summer for use by the Canadian Pacific Railway at their new coal handling docks, Fort William.

Power is received at 25,000 volts from a 3-phase, 60-cycle line and transformed through two sets of three 200-kw. single phase transformers, oil-insulated, water-cooled, 60-cycle star connected primary 14,500 volts, delta connected secondary 178 volts.

At the latter voltage it is delivered to the two 600-kw., 6-phase rotary converters shown in Fig. 1. These machines give 250/280 volt D.C. 2,400 amp. at 600 r.p.m., and are connected in parallel to the D.C. bus bars.

As the load is a rapidly fluctuating one, special provision had to be made to handle the peak loads. This has been very successfully taken care of by the use of a fly-wheel direct connected to a D.C. machine which alternately operates as a generator or motor across the D.C. bus bars. This is perhaps the first application of this system to the unloading of coal.

The D.C. equalizing machine is rated at 400 kw., 250 volts compound wound, and is capable of handling heavy overloads for short periods. The direct connected fly-wheel weighs 15 tons, made up of solid steel plates which gives a high factor of safety and is enclosed by heavy steel plate cover. This machine has a speed variation of from 450 to 600 r.p.m., depending on what load is being taken from the D.C. bus bars.

On light load the set automatically speeds up, taking power from the line, but with a heavy load on the line the speed tends to fall off and the generator feeds back on the line taking power from the fly-wheel. This speed variation is obtained by changing the shunt field resistance through a water rheostat, which is operated by a special torque motor.

Lightning protection is afforded by air-cooled choke coils and a three-phase type "A" electrolytic lightning arrester designed in this case for use on a 25,000-volt line. In Fig. 2 the arrester tanks are shown mounted in the gallery. This picture also gives a good idea of the open nature of the high-tension bus bar arrangement. The bus bars are connected to the incoming line and to the transformers through type "E" 35,000-volt, three-pole, hand-operated, automatic, oil circuit breakers.

Besides the transformers supplying power to the converters there are two 3-phase transformers for A.C. power purposes. They are rated at 100 kw. and transform from 25,000-volt primary to 2,200-volt secondary.

The switchboards are of black marine finished slate, mounted on angle iron frame. A total of 17 panels has been installed. The control panel for the incoming line is shown in Fig. 2 in front of the transformers, while on either side of it are the panels controlling the A.C. side of the rotary converters.

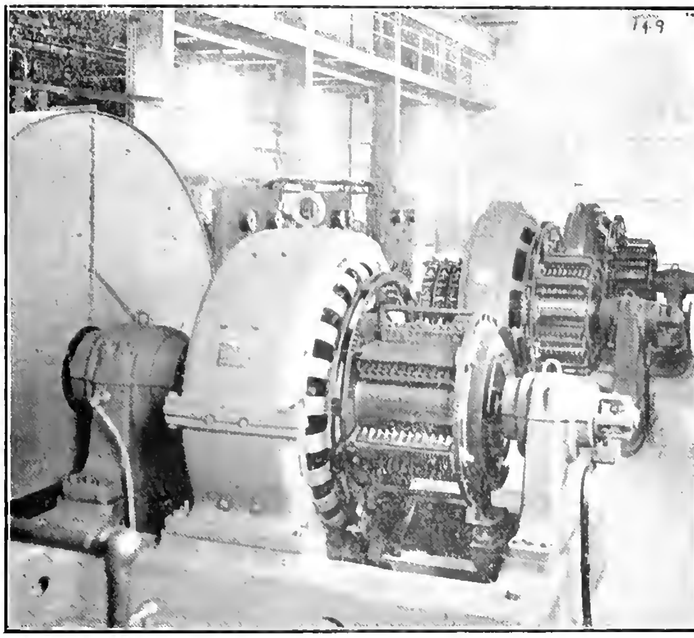


Fig. 1.

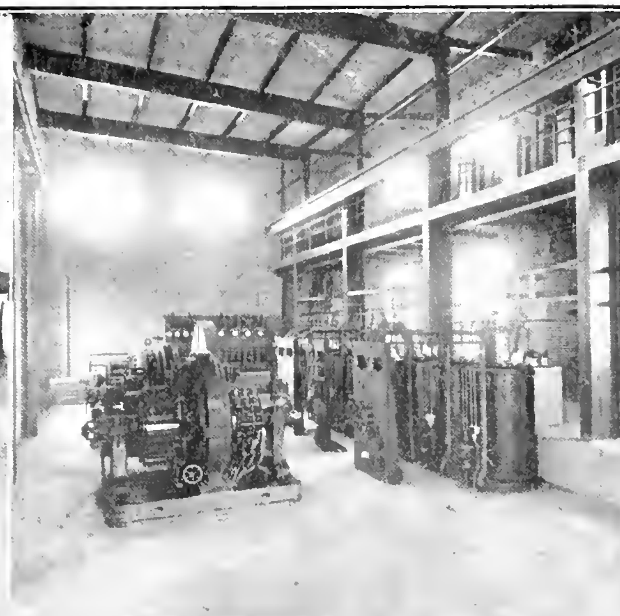

Fig. 2.

Mr. R. S. Kelsch was consulting engineer and the equipment was manufactured by the Canadian Westinghouse Company at their Hamilton works.

WATERPROOFING AND ACIDPROOFING CONCRETE FLOORS.

Where water is coming through concrete because of porosity, the Aberthaw Construction Company, of Boston, have found that a treatment of boiled linseed oil thinned down with gasoline will do much to cure the trouble. They have built roofs which were to cover delicate instruments in fortification range finders. These roofs proved porous, but a treatment with boiled linseed and gasoline cured the trouble permanently. It is a thoroughly good treatment for porous brick walls, has the merit of being very cheap, and the materials are reasonably available, and the most ordinary laborer can apply it intelligently enough. Besides this method, paraffine can be dissolved in gasoline and applied in a similar way with good results.

There is probably nothing that can be done to make a cement floor acid-proof. The treatment with linseed oil will retard the effect of acid, and of course particularly dense concrete will deteriorate more slowly than porous concrete. Where acid is to be used it is economical to give the floors several good coats of linseed oil and gasoline, and if possible during shut-downs to repeat them.

SOLVING CANADA'S TRANSPORTATION PROBLEM.

By J. L. Englehart.

The progress and development of Canadian railways has been marvellous. In 1835 there was not a mile of railway in the Dominion, there were only 16 miles in 1845. Ten years later, 1855, this had been increased to 877 miles. In 1865 there were 2,240 miles. While forty years later, 1875, there were only 4,804 miles in the whole Dominion.

The year 1885 was that in which the Canadian Pacific Railway completed the initial portion of that monumental labor, the Canadian Pacific Railway, and the mileage mounted to 10,733 miles. In 1895 the total was 15,977 miles, which in 1905 had increased to 20,487 miles, and in 1910 to 24,831 miles, while in 1911 no less than 25,400 miles of railway were completed and operated.

In addition to this there were many miles in the hands of contractors, being graded, and laid, or being laid.

Add to this 1,610 miles for double track, 5,550 miles of yard tracks and sidings, and a total of 44,193 miles of railway completed and under construction is obtained. Surely this is a record of which even our own grand Dominion has a just right to be proud.

The earnings of the railways were as follows:—

Year.	Earnings.	Expenses.	Per cent.
1905	$106,467,198	$ 79,977,573	75.2
1911	188,733,494	131,033,785	69.4

The capitalization amounted to the following amount, which is so large as to be hardly understandable:—

Stocks	$ 749,207,687
Funded debt	779,481,514
Total	$1,528,689,201

	Passengers carried.	Freight tonnage carried.
1909	32,683,309	66,842,258
1911	37,097,718	79,884,282

The following amounts were paid to employees of railways for labor:—

	1911.
Maintenance of way and structures.....	$18,157,696
Maintenance of equipment	15,544,057
Traffic expenses	1,564,399
Transportation expenses	36,832,034
General expenses	2,515,552
Total	$74,613,738

In 1909 the total was $63,216,662, and the ratio of gross earnings and operating expenses of total wages is shown below:—

	1910. Per cent.	1911. Per cent.
Ratio of gross earnings.........	38.61	39.53
Ratio of gross expenses.........	55.8	56.9

and is still mounting upwards.

The number of employees operating railways is 141,224—not including construction work.

Are the developments of the Dominion, and this construction of railways, are the efforts put forth, the efforts of the past ten years, to continue? If so, then we are justified in asking for co-operation.

Transportation is largely the question of the to-day of the to-morrow. Statistics show that railways have been practically re-built, rails, engines, rolling stock, ties per mile, telegraph and telephone, augmented to an extent that is hardly understood by even those who are interested in the matter. Stations, terminals, sidings, and buildings being enlarged, rails increased in weight, with these the other manifold demands that are made upon transportation companies of the day, call for largely increased capital expenditure; in very many instances, an addition of half, if not doubling the original capital.

Have tariff rates, passenger and freight, been increased? The answer is no.

Co-operation is permitted in trades, in labor, in every line. That is right, as it is equitable, for the reason, if none other, that it largely replaces wastefulness engendered by unfair competition, which has spelt ruin to so many enterprises.

In the present-day rush much of this has been forgotten by capital, labor, producer, consumer, manufacturer and the farmer. Each and every one has been enabled to improve their position, as well as the surrounding conditions. Then why not enlist, and work for the common weal, or accept the common woe, that transportation is sure to fall into, unless better counsels prevail?

Why cry out against the good work that has been, is being done by those who labor, and it is a labor, a ceaseless labor, of those who are in charge of transportation?

Consider what it would mean to you, to every one, in the face of the statistics that have been noted, if the problem of transportation were to be dealt with upon the narrow lines that appear to appeal to many. Instead of playing the game of clamor, why not aid and assist in improving the conditions?

Every transportation official knows there are shortcomings, every official is alive, as never before, to bettering the conditions. With passenger rates to-day averaging per passenger per mile, 1.94c., less than two cents per passenger per mile. With freight rates averaging per ton per mile 7.77 mills, less than eight-tenths of one cent for moving a ton (2,000 pounds) one mile.

Under these conditions, how are transportation companies to exist, if they cannot meet expenditures by receipts?

Transportation to-day means facilities that were not in vogue in days that are gone, rolling stock of every class and kind, engines of abnormal power, to which must be added the hundred and one requirements to-day demanded, which were not thought of in the past.

Transportation can be materially assisted by good roads, by diagonal roads. Expend millions, yes millions, upon diagonal roads. With sufficient good roads, you will largely solve that all-important question, transportation.

The motor vehicle of to-day is as essential to the farmer, the merchant, as to the reaper, the mower, or the thresher. The use of the motor would materially assist in arresting congestion. Many merchants to-day utilize motors for deliveries, saving dollars and cents.

The delivering of merchandise direct to the merchant or consumer by motor cars means a saving all round. With good roads, producers, farmers, manufacturers, can deliver less than carload lots, as well as carloads to central points, where the less than carloads could be transferred into carloads, transported with less transhipment, without breaking bulk and without transfer from one car to another. The motor car would largely serve the necessity, arresting congestion, if not removing it entirely.

That is the problem, to handle the many cars. That is the question that worries transportation men. Transportation companies have enlarged—are enlarging—every possible facility—terminals, sidings, motive power—but it is becoming a physical impossibility to transport the products of to-day within the time expected.

No more can shipments in less than carload lots nor for that matter in carload lots be delivered to the markets, in

the time that shippers demand. Neither power, rolling stock, terminal facilities, or tracks are adequate to meet such conditions. But with good diagonal roads, with motor cars, a revolution in transportation will be affected, largely decreasing less than carload shipments, lowering rates of freight, improving the facilities of transportation, removing, largely, the necessity of railways furnishing their cars for warehousing purposes, either to shipper, or merchant, who delay their orders for supplies until about the last day, if not hour, then clamor for delivery, while their own shortsightedness, their own pockets have all but forced the railways into a state of congestion.

Notwithstanding the largely increased number of miles of sidings, and terminals, enlarged warehousing facilities, extra trains, heavier engines, larger cars, congestion is a burning question and will be until the merchant, the shipper, the farmer, the producer, as well as the consumer, in fact till every one pulls his pound not for personal requirements but for the general good.

CONDENSATION UNDER CONCRETE ROOFS.

During the last year there has been considerable discussion in regard to the prevention of condensation under concrete roofs and it is, therefore, interesting to note the remarks in this connection of Leonard C. Wason, president of the Aberthaw Construction Company, of Boston. Mr. Wason states that under concrete roof, if the air is moist and hot, as it is in the principal part of a paper mill when the weather is cold outside, provision must be made to prevent condensation. Even with the best provision it is necessary in some places to provide for adequate ventilation, as dripping will occur whenever the air reaches the dewpoint. A thick concrete slab requires some insulation, even under only moderately bad conditions of dampness inside the building. Some of the roofing companies provide roofing felt, which goes on under the regular waterproofing of the roof surfaces. The disadvantages of this felt come from the fact that it is soft, and walking on the roof or particularly moving any heavy weight about on it will cut the roofing very readily. There is also the question of the permanence of the materials used in the felt. The cheapest and one of the most efficient methods of insulation that Mr. Wason knows of is to use on top of the roof slab a filling of porous concrete made up of screened cinders and cement. W. H. Ham, of the engineering office of French & Hubbard, of Boston, specifies as follows for such filling. His object is to get as spongy, porous material as possible and one that will have some cohesion, enough so that the roofing felt can be mopped down onto it, with the hope of its setting in position.

"**Cinder Fill.**—Concrete roofs shall be covered with a cinder concrete fill of thickness as shown. This fill to form crickets and other grades as indicated, minimum thickness, however, to be not less than three inches.

"Concrete for this work shall be mixed with one part by volume of Portland cement, fulfilling specifications required for other portions of the building work, and not more than ten parts by volume of clean, steam boiler cinders.

"The fill shall be placed as carefully as possible, so as to be left porous. After the fill has set up sufficiently to work over, the top surface shall be trowelled over with a flat coat of mortar to give a proper surface for the tar and gravel or other rolling material."

Difficulty develops with roofs on which furnace slag has been used and covered with an inch or more of sand finish, as the finish has expanded in the heat of the summer and has cooked up in big blisters.

BUILDING PERMITS

The following table, showing the value of building permits issued in 1912, compared with 1911, has been compiled from returns supplied to The Monetary Times by the various cities and towns direct:—

City.	1911.	1912.	Increase.	Increase per cent.
Berlin	$ 358,095	$ 842,613	$ 484,518	132.5
Brandon	1,024,529	1,166,214	141,685	13.7
Brantford	613,860	1,167,105	553,245	90.2
Calgary	12,907,638	20,394,220	7,486,582	58.0
Chatham	355,147	201,591	153,556(5)	43.1
Edmonton	3,660,327	14,446,819	10,786,492	294.7
Fort William	3,077,860	4,211,285	1,133,425	36.8
Galt	282,334	506,130	223,796	79.0
Halifax	508,796	579,775	70,979	13.7
Hamilton	4,255,730	5,491,800	1,236,070	29.0
Kamloops	530,860	559,703	28,847	5.4
Kingston	314,569	645,774	331,205	105.4
Lethbridge	1,033,380	1,358,250	324,870	31.3
London	1,036,880	1,136,108	99,228	9.5
Macleod	96,400	220,500	124,100	128.7
Maisonneuve	1,195,120	2,685,828	1,490,708	124.8
Medicine Hat	743,272	2,836,239	2,092,967	281.5
Montreal	14,579,952	19,641,955	5,062,003	34.7
Moose Jaw	2,475,736	5,275,797	2,800,061	113.1
Nanaimo	159,461	321,422	161,961	101.2
Nelson	167,000	275,000	108,000	64.6
New Westminster	1,124,587	1,634,528	509,941	45.2
North Battleford	240,080	896,970	656,890	273.3
*North Bay	157,406	462,675	305,269	194.2
Ottawa	2,997,610	3,621,850	624,240	20.8
Peterborough	345,372	465,905	120,533	34.7
(4) Point Grey	....	1,755,115	....	....
Port Arthur	595,180	2,494,179	1,898,999	318.9
Preston	244,375	337,160	92,785	37.7
Prince Albert	921,595	2,006,925	1,085,330	117.7
Prince Rupert	265,771	316,717	50,946	19.1
Red Deer	237,220	387,640	150,420	63.2
Regina	5,099,348	8,047,309	2,947,961	57.7
St. Catharines	265,435	811,335	545,900	205.6
St. John	572,700	647,200	74,500	13.0
Saskatoon	5,004,326	7,640,530	2,636,204	50.6
(3) South Vancouver	2,500,000	2,600,000	100,000	4.0
Stratford	103,500	367,233	263,733	255.3
Sydney	495,642	656,111	160,469	32.3
Toronto	24,374,539	27,401,761	3,027,222	12.4
Vancouver	17,652,642	19,428,432	1,775,790	10.0
Vernon	202,982	446,142	243,160	120.2
Victoria	4,260,315	8,208,155	3,947,840	92.4
Welland	342,808	469,744	126,936	33.9
(2) Weyburn	....	766,760	....	....
Windsor	739,595	1,098,063	358,468	48.4
Winnipeg	17,716,750	20,475,350	2,758,600	15.5

*Value of permits from May 17th to December 31st, 1911. No record kept previously.

(2) Figures for 9 months—building permit by-law brought into force in April, 1912.

(3) Estimated—no record kept previously to November 23rd, 1911.

(4) From May 13th to December 31st. No record kept previously to May, 1912.

(5) Decrease.

The value of the permits of 44 cities in 1911 was $135,000,000, and of 46 cities last year $196,000,000, an increase of $61,000,000.

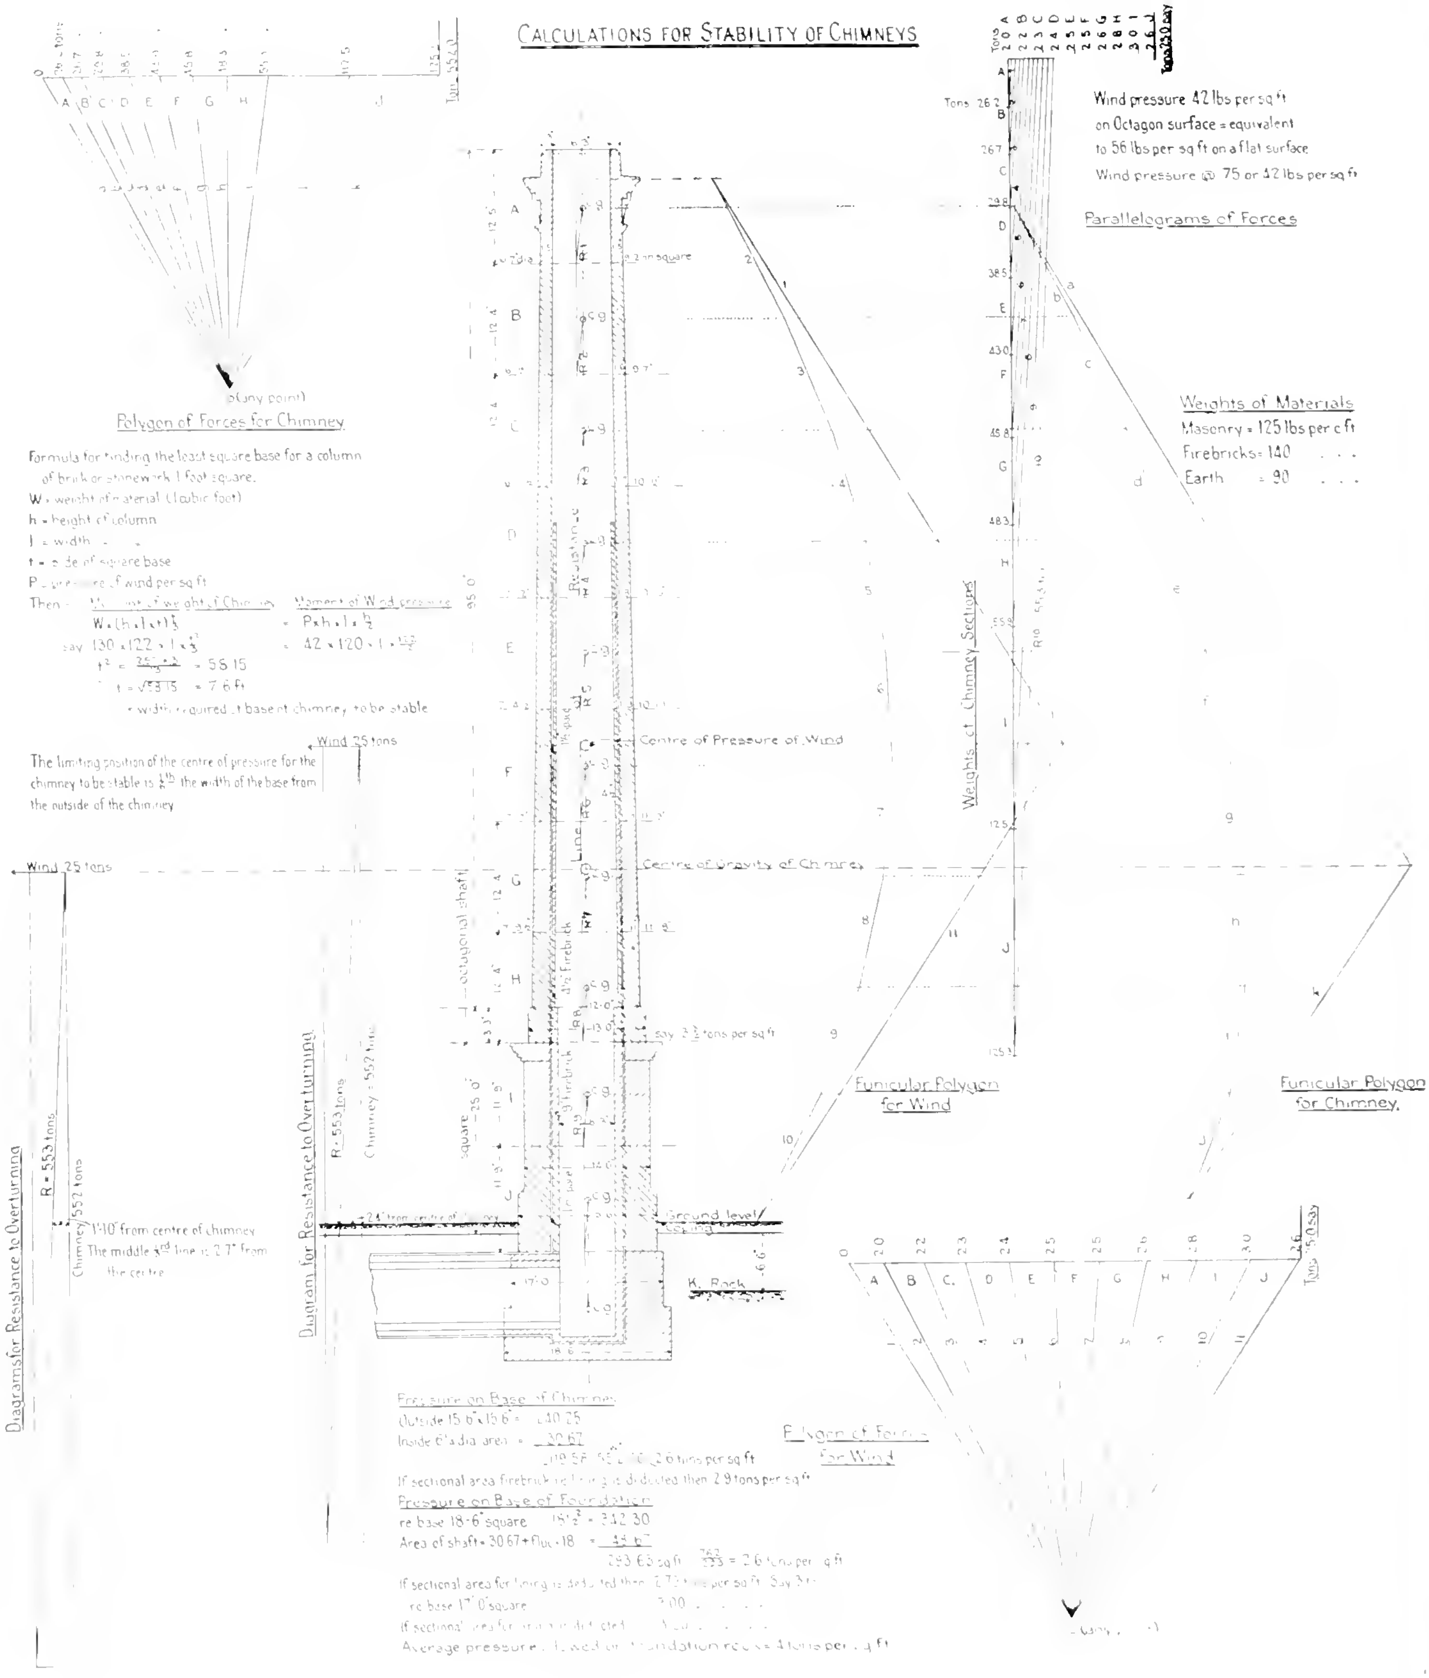
CALCULATIONS FOR STABILITY OF CHIMNEYS.

By Leonard Goodday, C.E. and M.E., late of the British Admiralty.

Calculations for the stability of chimneys are from time to time given, but as a rule simply for the turning point at the base, and level with the ground, and this is not sufficient of itself, when it is so essential to have it perfectly safe in every way, especially when the chimney is high; such, for instance, as one for a factory or engine house.

The one which it is proposed to illustrate fully is one for an engine house which was carried out some years back in the east, and which I will now explain step by step in detail

To commence the design, determine the height of the stack necessary for the draught, etc., and by moments, as shown to the left, find the required base t which, in this case,



is 7.6 ft. for a column of brick or stonework 1 ft. square to be stable. As the wind may come from any quarter, the base, when constructed, must be at least 7.6 x 2 square, i.e., 15.2 ft. x 15.2 ft. Of course, the greater the weight of stack, the safer the structure, and the sectional area of base will be, comparatively speaking, very little more than this for the same height.

This chimney is octagon in section, and the assumed pressure of wind 56 lbs. per square ft. on a flat surface; and the average pressure in this case becomes .75 of 56 lbs., or 42 lbs. per square foot, as given in sketch.

The chimney which is found necessary to be 120 ft. in height from the ground may now be designed in the usual proportion, and for the facility of calculation divided in equal sections of, say, 12 ft. 4 in., each section being lettered A, B, C, etc., as shown.

The next step is to find the pressure of wind at 42 lbs. per square foot on each of the above sections, the total result of which is found to be 25 tons, as shown on the right hand of diagram.

Next, by parallelograms of forces, find graphically their resultants in the following way: Draw the vertical line to scale representing the weight of section A, viz., 26.2 tons, and the horizontal force of wind, viz., 2.0 tons, and draw in the line R 1, which gives the resultant force for that section. Produce the vertical line representing A until it equals A plus B, then with the combined weights of the two sections A and B, viz., 26.2 plus 26.7 tons, and with the wind pressure, viz., 2.0 and 2.2 tons on the two sections A and B respectively, draw the resultant force R 2 and continue in this way until the total resultant force R 10, viz., 553 tons, is obtained at the base of section J.

It will be noticed that the lettering of the sections A, B, C, etc., of the chimney, with their weights, are shown on the left side of the parallelograms of forces, so that mistakes will be avoided.

Now put in the centre of gravity of each section, and draw in the lines R 1, R 2, etc., from the centre of gravity of A, B, C, etc., to the bottom of each section respectively, and parallel to R 1, R 2, etc., shown on the parallelogram of forces, and connecting these points by a line which is the line of resistance, and well within the middle third of each section.

The result of this investigation shows graphically that if this chimney were built up in sections placed one upon the other, only with their bases horizontal, and without being bonded together, there would be no danger of it being "crippled."

The next step is to determine the resistance to overturning of the whole chimney, first, when the centre of pressure of the wind is taken, and secondly, when the total pressure is taken at the centre of gravity of the chimney. It will be necessary to first find these points, the method of which is as follows:—

For the centre of pressure of wind: Draw the horizontal line, as shown, to the right, representing the pressures on the sections A, B, C, etc., by the pressures of each, viz., 2.0, 2.2 tons, etc., making a total of 25 tons. Take any point O, and connect the lines representing the pressures to this point, as shown by the numbers 1, 2, 3, etc. This figure represents the polygon of forces for wind, the letters A, B, C, etc., being the sections of chimney opposite each line of pressure respectively.

Next draw in the horizontal dotted lines from the centre of gravity of the sections A, B, C, etc., and also the line shown where the wind is assumed to commence to take effect.

Now draw the lines 1 and 2 from this last line parallel to the lines 1 and 2 on the polygon, the line 2 being drawn until it cuts the horizontal line from the centre of gravity of section B. From this point of intersection draw the line 3 parallel to line 3 on the polygon, until it cuts the horizontal line from the centre gravity of section C, and continue in the same way until line 10 is drawn, letting it cut the ground level. From this point of intersection draw line 11 parallel to line 11 on the polygon until it cuts line 1 produced. From this point draw a horizontal line until it cuts the chimney, and which is the centre of pressure of the wind. The figure just completed is called the Funicular polygon for wind.

In the same way the polygon of forces for the chimney may now be constructed as shown to the left, and from this can be obtained in the same way, the funicular polygon and centre of gravity for the chimney, the only difference being that this last polygon is commenced from the line from the centre of gravity section A, and finished from the line from the centre of gravity of section J.

On the line for the centre of pressure of wind draw a line representing 25 tons total wind pressure, and a vertical one representing 552 tons the dead weight and centre line of chimney, and complete the resolution of forces. The resultant R works out to 553 tons, and is the resistance to the overturning at ground level. This line is found to be 2 ft. 4 in. from the centre of chimney.

In a similar way construct another diagram, but from the line for the centre of gravity of chimney. The resultant R or line of resistance is found to be 1 ft. 10 in. from the centre of the chimney.

Now, the chimney at ground level is 15 ft. 6 in. square, and consequently its middle third is 5 ft. 2 in. or 2 ft. 7 in. on either side of the centre, and as the two resistances to overturning are 2 ft. 4 in. and 1 ft. 10 in. respectively, the chimney is perfectly safe.

The last and equally important step is for the foundation which should be made perfectly solid and of concrete, the strength of which should be according to the total pressure, including everything, on the base of the foundation.

The trial sectional area was taken at 21 ft. 6 in. square, which gave too much over the load allowed per square foot. Then 17 ft. 6 in., which was found to be too light, and lastly 18 ft. 6 in. square was adopted.

It will be seen that the greatest weight per square foot on base of foundation is 3.0 tons, and that the safe load allowed on the rock is 4.0 tons in that locality.

For every important and heavy structure borings should always be taken, and the ground thoroughly tested, so that there will be no chance of settling, and causing continual trouble and expense, and which can be avoided by having the advice of an expert on foundations.

It is hoped that this article will be of service to those seeking advice on this subject.

WASTE OF NATURAL GAS.

Much has been written about the saving effected by using natural gas in gas engines to generate power, instead of burning the gas under boilers to generate power from steam. Experiment has shown that the amount of gas required per hour, for the development of one horse-power, varies from 9 cubic feet, with the highest type of large internal combustion engine, to 130 cubic feet with the ordinary steam engine. In other words, the efficiency of the gas is over fourteen times as great when used in gas-engines as when used for generating steam under boilers.

The province of Ontario has reduced the waste of natural gas to a minimum by causing all abandoned wells to be plugged and by levying a tax of two cents per thousand feet, with a rebate of 90 per cent. when the gas is used.

ABUSES IN WATER FILTRATION.

The success of a water filtration plant depends, first, upon the selection of the method of purification best suited to local conditions, and second, upon the proper operation of the works after they have been installed. This subject was discussed at the last meeting of the New England Waterworks Association by Mr. Gilbert H. Pratt, chemist of the Rhode Island State Board of Health, who pointed out some of the things which contribute to the production of unsatisfactory results.

Slow sand filtration for a water high in algæ is not to be recommended, he said, because of the undue clogging of the beds, but by the use of aeration and prefilters conditions may be greatly improved. Plain sand filtration should not be relied upon to treat a very highly colored water. Rates of filtration should not be changed quickly, for such practice tends to disturb bacterial action at the surface of the bed.

A slow sand filtration plant which would handle a given water satisfactorily might, as was the case in Providence, be installed without covering the beds. As soon as a hard winter struck the plant the beds would become covered with ice, and it would be impossible to get at the surface to clean without removal of the cakes of ice. This condition occurred in Providence for a short time during 1907, finally necessitating opening the river gate, and the use of raw water for about two weeks or so before the weather moderated and before the ice could be removed. This experience resulted in steps immediately being taken to cover the beds. This experience, Mr. Pratt believes, should serve as a lesson against such open installations in New England.

One of the easiest ways to abuse a plant is to put it into the hands of inexperienced operators, especially in the case of rapid sand filters, where the supervision must be particularly close and where tests for color and alkalinity must be made to regulate the doses of chemicals used. One plant had operated for a number of years satisfactorily in a bleachery. When Mr. Pratt was consulted with regard to difficulties which were occurring he found that the parties in charge did not have an understanding of the question of alkalinity control of the plant ,and the residual alkalinity of the effluent had dropped to a point where the water was passing the plant at times in an acid condition, or at best with an extremely low alkalinity, resulting in after-coagulation in the vats and throughout the system. This condition had been caused by a mill above discharging a larger amount of acid wastes in the river than at the time the formula for operating the filters was figured. The addition of alkalinity to the water put the plant back into its former good condition.

At another installation the man in charge of the plant, for some reason or other, was assigned to night duty, and he was attempting to make his control tests for color and alkalinity at night by artificial light. This, of course, gave far from accurate results. Another trouble at this plant was that the one man was expected to operate the flow of chemicals from the tanks, which were located in the pump house, and at the same time attend to washing the filters in a filter house which was located about one-eighth of a mile away. This spreading out of the plant made it impossible for the lone operator to properly attend to the dosing, and the result was that the flow of chemicals varied from time to time, with resulting poor output from the plant.

At another plant trouble due to low residual alkalinity was found to exist, and the output contained undecomposed sulphate of alumina. Investigation showed that this operator was using an indicator solution many times too strong and the alkalinity tests which he was obtaining were absolutely inaccurate.

At still another plant the biggest difficulty discovered when troubles arose seemed to be with the application of the chemicals, which required an extremely close control on account of an influence on the color of the filtered water, as the residual alkalinity became too high. The engineer was a man who had been for years pumping water out of the reservoir under the old system, and could not be made to realize that careful supervision was necessary. He grossly neglected controlling the flow of the chemicals. These operating troubles immediately ceased when a new, competent engineer was put in charge of the plant.

The effect of an abnormal amount of organic matter or algæ in comparison with the color of the water sometimes has resulted in an under-dosing with coagulant, as this additional amount of organic matter has seemed to prevent proper coagulation with resulting incomplete removal of the constituents which it was intended to remove, and the effluent has contained alumina and abnormal amounts of color and algæ. Proper dosing in view of the above-mentioned conditions has resulted in excellent work from this plant.

Another abuse oftentimes is attempting to operate a plant with every possibility for good results, by methods which some man of limited experience may have used at some other plant, meeting entirely different conditions. Such cases have been capable of adjustment when instructions have been given which had in mind the type of plant and the raw water to be handled.

In connection with the operation of plants of the mechanical type, it is essential that the night man should be one who can be depended upon to stay awake, as a nap for an hour or two may result in throwing the whole operation of the plant out of adjustment for several hours.

CANADIAN RAILROAD EARNINGS.

The following are the approximate gross earnings of Canadian Railroads month by month.

	Canadian Pacific Railway.			Grand Trunk Railway.			Canadian Northern Railway.		
Month.	1911.	1912.	Increase.	1911.	1912.	Increase	1911.	1912	Increase.
	$	$	$	$	$	$	$	$	$

ELECTRIC RAILWAYS IN CANADA.

During the next few years, there is likely to be considerable development in electric railways in Canada. The large railroad corporations are considering the advisability of electrifying certain existing steam lines and building new electric roads for suburban service. Capitalists and charter holders are estimating the cost of linking small towns by electric roads. The present appears to be a time of preparation for the inauguration of an electric railroad era, especially in the older provinces of the Dominion. It is most marked in Ontario. The accompanying table shows to what extent the electric railroad is already in vogue in that province. The statistics are for the year 1911, the latest for which official figures are available.

The subscribed capital of twenty-eight roads in Ontario is $16,000,000. The paid-up capital totals $14,000,000, and the outstanding bonds $12,000,000. Their total liabilities are $36,737,000 and total assets $36,711,000. The operating results are interesting. With the exception of five, they all showed a surplus. The largest deficit, amounting to $421,967, was that of the Hamilton Radial. The total receipts of the twenty-eight were $8,000,000, and the total expenses $6,620,000, giving a total surplus of $1,430,000.

Passenger fares accounted for the greatest share of receipts, revenue from freight and other sources being comparatively small. It is for passenger traffic that our transportation interests are apparently agreed that electric traction is most suitable. The receipts may be summarized as below:—

Receipts from	Amount.
Passenger fares	$6,811,493
Freight	238,557
Mail service and express	8,809
Other sources	163,415

The actual operating figures are of significance to railroad men and to investors particularly. The street car systems in the large cities naturally show the largest car mileage run, Toronto leading the way in Ontario with a mileage of more than 16,000,000. The cost of operation per car mile shows some striking contrasts. The lowest figure is that of the Cornwall Street Railway, $07.5. The highest is that of the Hamilton and Dundas Railway, $43.1. Of 22 roads, the cost of operation per car mile in 14 cases exceeded $20, and in eight cases was under that amount.

The smallest length of track is that of the Huntsville and Lake of Bays Railway, which has only one mile. It serves a holiday traffic, connecting boats. Last year it carried 14,000 passengers. The greatest mileage, 110.88, is that of the Toronto Street Railway. The number of passengers carried by the electric roads of Ontario in 1911 was 181,259,748, and the year before 157,539,893.

Among the important electric roads in other provinces are the following:—

Company.	Mileage.
Halifax Electric Tramway Company	13.15
Montreal Street Railway	230.97
Quebec Railway	17.00
Winnipeg Electric Railway	119.46

Electric roads are also operated or contemplated in several cities west of Winnipeg, including Brandon, Moose Jaw, Regina, Saskatoon, Calgary, Edmonton, Lethbridge, Vancouver and Victoria. The system in the two latter cities, as well as in smaller British Columbia municipalities, is operated by the British Columbia Electric Railway. It has 234 miles of railway.

In the entire Dominion the mileage of electric roads in 1911 was 1,223. The growth of first main track mileage since 1900 is as follows:—

1902	557.59
1903	759.36
1904	766.50
1905	793.12
1906	813.74
1907	814.52
1908	902.03
1909	988.97
1910	1,047.07
1911	1,223.73

The capital liability of electric railways in Canada was increased from $102,044,979 in 1910 to $111,532,347 in 1911.

The following statement will show the facts with regard to capital liability for five years:—

	1907.	1908.	1909.	1910.	1911.
Stocks	$43,491,746	$50,295,266	$51,946,433	$58,653,826	$62,251,203
Funded debt	31,166,976	37,114,619	39,658,556	43,391,153	49,281,144
Total	$74,658,722	$87,409,885	$91,604,989	$102,044,979	$111,532,347

The gross earnings from operation for 1911 were $20,356,951.70—an increase of $3,256,162.22 over 1910.

The income for 1911 came from the following sources:—

Car earnings: Passengers, $19,130,376.22; freight, $744,179.11; mail and express, $88,233.13; other car earnings, $100,930.12. Total car earnings, $20,063,718.58.

Miscellaneous earnings: Advertising, $66,147.33; rent of buildings, etc., $22,551.98; rent of tracks, $13,650.94; rent of equipment, $58,624.40; sale of power, $43,698.24; other earnings, $88,560.23. Total, $293,233.12. Gross earnings from operation, $20,356,951.70.

The following is a summary of statistical facts, compiled by Mr. J. L. Payne, comptroller of railway statistics, Ottawa, and relating to electric railways in Canada:—

	1909.	1910.	1911.
Total mileage	988.97	1,047.07	1,223.73
Paid-up capital	$91,604,989	102,044,979	111,532,347
Gross earnings	$14,611,484	17,100,789	20,356,952
Net earnings	$4,962,501	5,383,276	6,592,335
Earnings—			
Passenger traffic	$14,080,755	16,125,995	19,130,376
Freight	$386,092	575,537	744,179
Mail and express	$110,452	68,604	88,233
Other sources	$34,185	51,241	100,930
Total operating expenses	$8,885,235	10,121,781	12,096,134
Maintenance of way and building	$643,135	797,895	920,875
Cost of motive power	$1,445,227	1,586,927	2,001,543
Maintenance of cars	$1,184,287	4,814,762	5,768,085
General operat'g charges	$5,612,041	1,406,943	1,610,099
Total car mileage	60,152,846	65,249,166	72,618,806
Passengers carried	314,026,671	360,964,876	426,296,792
Tons of freight carried		852,294	2,496,072

ONTARIO HYDRO-ELECTRIC COMMISSION.

The total revenue of the Ontario Hydro-Electric Commission for the past year reached $511,801.88. These receipts were for power delivered, including charges for administration, general expenses, operation, maintenance and interest. The expenditure reached $456,635.43; the total for the fourth quarter, with a tremendous increase in power purchased, was but $28,000 above that of the first quarter. The surplus on the year was $55,166.45, half of which was rolled up in the last quarter. This has been nominally set aside as a "depreciation reserve."

CONTENTS OF THIS ISSUE.

THE CHICAGO DRAINAGE CANAL DECISION.

In an elaborate opinion denying the petition of Chicago for permission to divert from Lake Michigan increased water, Secretary of War Stimson deals with the principal points of argument which have developed during the negotiations carried on in the past few months.

We treated this question of increased diversion of water for the Chicago Drainage Canal editorially in our issues of April 25th and July 18th, 1912, and we are glad to note that the arguments therein presented have been given due weight in the decision arrived at. Secretary of War Stimson states that he has reached the following conclusions:—

> That the diversion of 10,000 cubic feet per second from Lake Michigan, as applied for in this petition, would substantially interfere with the navigable capacity of the navigable waters in the Great Lakes and their connecting rivers.
>
> That being so, it would not be appropriate for me, without express Congressional sanction, to permit such a diversion, however clearly demanded by the local interests of the sanitation of Chicago.
>
> That on the facts here presented no such case of local permanent necessity is made evident.
>
> That the provisions of the Canadian treaty for a settlement by joint commission of "questions or matters of difference" between the United States and Canada offer a further reason why no administrative officer should authorize a further diversion of water, manifestly so injurious to Canada, against Canadian protest.

The opposition to the application of the Sanitary District for permission to divert 10,000 cubic feet of water per second, instead of the 4,167 feet, at present authorized, was pronounced, on the part of twenty-three cities and six States, the navigation interests of the Great Lakes, the Canadian Government and private interests, and Mr. Stimson states that this opposition marks a distinct change in the situation from the time the canal was projected.

The specious argument which formed the basis of Mr. Isham Randolph's report in behalf of the Sanitary District, that the reduction in depth on the lakes caused by the increased diversion would be of no consequence, in view of the fact that greater natural changes occur through winds and other conditions, is taken at its true worth, and Mr. Stimson states the fact that the oscillations would remain as before, that low water would fall lower and high water would rise less high, and the average draught of vessels would have to be diminished to that extent. He reiterates that every drop of water taken out of the lake at Chicago tends to nullify the costly improvements on the harbors, etc., as well as to inflict even greater loss upon the navigation interests.

Secretary of War Stimson is to be congratulated on this eminently fair and just opinion. It is seldom that a report comes to hand which shows such fair-mindedness and a desire to protect all the interests affected. From Canada's standpoint the decision could not be improved upon. Secretary Stimson notes the fact that the International Waterways Treaty of 1909 gives Canada certain rights which must be respected. We are glad to note that he has shown this respect in his decision.

THE PUBLIC HEALTH ACT OF ONTARIO.

In this issue under the heading, "Changes in the Public Health Act of Ontario," will be found the important changes in Public Health legislation which took effect at the beginning of this year in the Province of Ontario. We are in hearty sympathy with all of these, but we are sorry to note that as yet no provision has been made for the employment of an engineer to work in co-operation with the Provincial Board of Health. In the editorial columns of the issue of September 19th, 1912, we stated that the necessity for the securing ot the assistance of expert sanitary engineering experience to co-operate with Provincial Boards of Health was very urgent.

We note that plans for the establishment and extension of waterworks and sewerage systems must be approved by the Ontario Board of Health before any debentures can be issued to raise money for these purposes. The Board may direct as to the maintenance, repairs and improvements of such systems, and upon the certificate of necessity from the Board, work may be undertaken in the interests of public health without a vote of the ratepayers.

There is little question that this legislation will aid towards placing the control of the pollution of waterways in the hands of the Board of Health, a result which will mean safer drinking water supplies, and, therefore, reduction in the number of cases of deaths from typhoid fever and other water-borne diseases.

We are unable to see how this legislation can be carried out with the present staff of the Ontario Provincial Board of Health. It is unfair to the engineering profession that their plans should be submitted to members of the medical profession without competent engineering advice available. If this legislation is to be effective, and it is the desire of everyone that it should be effective, the Board of Health must have on their staff a thoroughly competent hydraulic and sanitary engineer, or the advice of such a man must be available for them at such times as they require.

EDITORIAL COMMENT.

We wish to remind all members of the Canadian Society of Civil Engineers of the coming Annual Meeting, to be held in Montreal on January 28th, 29th and 30th. Every member should make a strong effort to be present.

* * * *

Quebec has made a distinct step forward in its treatment of the Good Roads question. It was announced this week that Mr. J. O. Mousseau, member of the Provincial Parliament for Soulanges, has been appointed Minister of Good Roads. This new provincial portfolio should be the means of concentrating the handling of the construction and maintenance of good roads throughout Quebec. The province has voted $10,000,000 for the construction of good roads. This, coupled with the fact that a Cabinet Minister will be directly in charge of the work, should do much to improve road conditions and to aid in opening up the province.

* * * *

The Board of Control in Toronto has recommended to the City Council that a by-law be passed to sanction the erection of a seventeen-story building on King Street. They very naively state that the building would be of fireproof construction throughout. This question of the height of buildings in this city should be settled once and for all, by taking it out of the hands of the Board of Control or the City Council to give permission to erect a building over ten stories high. Toronto streets are far too narrow to permit of the increased congestion of traffic and the evil effects on sunshine, incidental to the erection of such structures.

PROGRAMME OF ANNUAL MEETING, CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting for the election of officers and members of council for 1913, and for the transaction of business, will be held as follows in the rooms of the society, 413 Dorchester Street West, Montreal.

Tuesday, January 28th.—10 a.m.—Meeting for the nomination of scrutineers; receiving the report of council; reception and discussion of reports of committees, and transaction of the general business of the society.

1 p.m.—Adjournment for luncheon, to which the visiting members are invited by the members resident in Montreal.

3 p.m.—Continuation of the business meeting for the discussion of reports, etc.

4 p.m.—An address by the retiring president, Mr. W. F. Tye.

8 p.m.—Smoking concert in the new quarters of the society, 176 Mansfield Street. Complimentary.

Wednesday, January 29th.—Visit to the Montreal Steel Works. The party will leave the Windsor Hotel at 10 a.m. sharp. By the courtesy of the Montreal Tramways Company special street cars will be provided to convey the party to and from the works at Longue Pointe.

3 p.m.—Business meeting. Discussion of reports.

8 p.m.—Annual members' dinner.

Thursday, January 30th.—10 a.m.—Meeting for the reception of reports of scrutineers. Continuation of the business of the annual meeting.

2.30 p.m.—The meeting will reassemble, if necessary, for the conclusion of business. On adjournment a meeting of the council will take place.

By the kindness of the railways of the Eastern Canadian Passenger Association, members and their families who have paid a full one-way first-class fare going to the meeting in Montreal, will be returned free on presentation of a Standard Convention certificate signed by the ticket agent from whom a ticket has been procured at the point of commencement of the journey. The certificate is to be endorsed by the secretary of the society, and to be vised by a special agent of the Passenger Association who will be in attendance at the meeting from 3 p.m. to 6 p.m. on Wednesday and Thursday, January 29th and 30th. A fee of 25 cents will be charged by the Passenger Association in each case. Tickets may be purchased and are available three days before the commencement of the meeting and the return journey may be made three days after its conclusion.

A further extension of time will be granted to persons residing west of Fort William, making the free return available for 15 days after the close of the meeting; the ticket to Montreal having been purchased at any time and receipt obtained therefor on the Standard Convention form as above.

Tickets to the luncheon on Tuesday and to the annual dinner on Wednesday may be procured at the rooms of the society. Prices: Luncheon, $1.50 to local members; dinner, $3.50. Secretary, Prof. C. H. McLeod.

DEVELOPMENT WORK ON THE C. P. R.

The Canadian Pacific Railway again enjoyed a period of progress and development during its past fiscal year, which ended on June 30th, 1912. Sir Thomas Shaughnessy, the president and chairman of the company, had a pleasing statement to submit to the shareholders. Most interesting to the country at large were the extensions and new connections, made and proposed by the company. For the purpose of securing a shorter and more expeditious route between Quebec and points in New England, served by a friendly connection, the Boston and Maine Railroad, the directors thought it advisable to lease the Quebec Central Railway, forming the connection between Sherbrooke and Levis, together with branch lines from Beauce Junction to St. Sabine, and from Tring to Megantic, all in Quebec, making a total of about 253.5 miles of railway, at a rental based upon the interest on the outstanding 1st, 2nd and 3rd mortgage bonds of the Quebec Central Railway Company, and a dividend on the outstanding capital stock of that company at four per cent. per annum for four years from July 1st, 1912, and thereafter at the rate of five per cent. per annum.

The Shuswap and Okanagan Railway, 51 miles in length, extending from Sicamous Junction, on the main line in British Columbia, to the head of Okanagan Lake, was leased to the company on its completion in 1892 for a period of 25 years, and it was a condition of the lease that the company should pay by way of rental forty per cent. of the gross earnings of the line, as defined in the lease, in quarterly amounts.

The Georgian Bay and Seaboard Railway, recently built under Canadian Pacific Railway auspices between Victoria Harbor, on Georgian Bay, and Bethany, Ontario, to provide a shorter and more economical lake and rail route between Western Canada and the Atlantic Seaboard, proved more expensive than was anticipated, due to the character of the line that it was finally determined to construct and to other conditions. The power conferred by parliament on the Georgian Bay and Seaboard Railway Company to issue bonds for the purposes of its undertaking was originally limited to $30,000 per mile, but at the last session of parliament this amount was increased to $55,000 per mile, and the directors have entered into a supplementary agreement with the Georgian Bay and Seaboard Railway Company to increase the limit of that company's bond issue, upon which this company has, by virtue of the lease approved October 3rd, 1906, agreed to pay interest by way of rental, from $30,000 to an amount not exceeding $55,000 per mile of railway.

Instead of continuing the double track from Glen Tay to Agincourt, on the Ontario and Quebec Railway between Montreal and Toronto, it has been decided to secure a line between these two points that will serve the territory further south, and will reach several important towns on the north shore of Lake Ontario. An agreement has, therefore, been made with the Campbellford, Lake Ontario and Western Railway Company for the construction, under the company's supervision and control, of that company's railway, 184 miles in length, between Glen Tay and Agincourt, both in Ontario, and for the lease of the railway when completed to the company for a period of 999 years, at a rental equivalent to four per cent. per annum on the bonds of the Campbellford, Lake Ontario and Western Railway Company.

The present route between points in the Kootenay and Boundary Creek Districts, of British Columbia, and the Pacific Coast is long and expensive, and the best means of securing a more direct route has engaged the attention of the directors for some time past. The Kettle Valley Railway Company, having a Dominion charter, covering the territory between Midway, the terminus of your Boundary Creek Line, and Merritt, on your Nicola Line, undertook to build the railway between these points, under the advice and to the satisfaction of the directors, upon condition that the company would lease the line, approximately 270 miles in length, and the branch line along the North Fork of the Kettle River, 24 miles in length, whenever and as soon as the Kettle Valley Railway Company is competent to make a lease, paying by way of rental the interest at four per cent. per annum on the bonds of the Kettle Valley Railway Company, any subsidy received from the Dominion or Provincial Government, or from any other source, to be applied on an agreed basis towards the cost of the construction of the railway and a corresponding reduction in the amount of bonds to be issued. This line will give access to a large and important section of the province in which development should quickly follow railway facilities.

The amounts appropriated for new works, exclusive of railway construction, were abnormally large, in the year under review. For the enlargement of terminals, additional shops, second tracks, sidings and improvements of every variety calculated to improve the efficiency of the railway system, and to facilitate the movement of the large and increasing traffic, the amount of $30,000,000 was authorized to be expended and orders for locomotives and cars, representing an expenditure of $25,750,000, were placed. Many of these works cannot be completed with the season, with the limited amount of labor available, but no effort is being spared to meet the convenience of the public and to strengthen the position.

The shareholders last year sanctioned a lease of the Kingston and Pembroke Railway, extending from Renfrew, on the company's main line west of Ottawa, to Kingston, on the St. Lawrence River, and from Godfrey village to Zanesville Mine, in Ontario, a total distance of 107.5 miles; a lease of the Alberta Central Railway, extending from Red Deer to Rocky Mountain House, in Alberta, a distance of 65 miles; an agreement with the St. Mary's and Western Ontario Railway Company cancelling existing arrangements and substituting a lease of their property for a period of 999 years at a rental equivalent to four per cent. per annum on bonds issued or to be issued by that company with your consent to an amount not exceeding $25,000 per mile of their railway; and a deed of conveyance of the Cap de la Madeleine Railway, about 4 miles in length, connecting the railway near Three Rivers, in Quebec, with Cap de la Madeleine, on the St. Lawrence River, and with the Wayagamack Pulp and Paper Company's works.

An indenture of lease from the government of New Brunswick, as lessor, to the company, as lessee, of the New Brunswick Coal and Railway for a term of 999 years at a rental of fifty per cent. of the net earnings of the said railway, as defined and calculated in the said proposed lease, will be submitted for your sanction. This railway extends from a point in the vicinity of Minto, in the County of Sunbury, to a point of junction with the Intercolonial Railway, near Norton, in the County of Kings, in the Province of New Brunswick, a distance of approximately 58 miles, and will form a portion of a connection between Canadian Pacific Railway and a coal mine in New Brunswick, now in process of development.

The following branch lines of railway in Manitoba, Saskatchewan and Alberta are being, or will be extended, viz., Boissevain to Lauder, 37 miles; Weyburn Lethbridge branch, 125 miles; Kerrobert northeasterly branch, 11 miles; Wilkie Englia branch, 4 miles; Swift Current Northwesterly Branch, 80 miles, Suffield Southwesterly Branch, 55 miles.

THE MONTREAL TUNNEL FOR THE CANADIAN NORTHERN.

S. P. Brown, M. Am. Soc. C.E., M. Am. Soc. M.E., managing engineer, Mackenzie, Mann and Co., and chief engineer, Canadian Northern Montreal Tunnel and Terminal Co., read a paper on tunnelling before the Canadian Railway Club in Montreal recently in which he dealt with the subject most exhaustively, covering its history and the questions of classificaton, surveying, design, ventilation, signals, tracks, construction, plant, excavation, and linings very thoroughly. Following are extracts which refer particularly to the C.N.R.'s Montreal tunnel.

Entries into cities, where natural surroundings make tunnels imperative where city ordinances prohibit grade crossings, where land values do not allow of a private right of way for an open cut with bridges at street crossings, or where grades or cost of construction and maintenance make an elevated viaduct inadvisable or impossible.

The Canadian Northern is just completing its transcontinental system, for which terminal facilities in Canada's principal city are essential, especially as this city is the main eastern seaport during the busiest half of the year. Montreal's natural location, between the St. Lawrence River and Mount Royal, made the problem of entry appear complicated. To enter from either end of this narrow strip meant a detour that was undesirable, and might possibly have resulted in two separate stations for the east and west-bound traffic. Grade crossings were out of the question. Cut, cut and cover subway, or elevated viaduct would have necessarily been of considerable length, which would have been difficult and expensive in many ways. The natural alternative was a tunnel; and as by developing the country back of the mountain, suburbanly, for Montreal's rapidly increasing population, much of the expense of the improvements could be covered, it was the only logical course. Furthermore, the topography of the city—combined with the distribution of business activity of different sorts—made the actual terminal location, yards, etc., equally logical and simple.

The line of the Canadian Northern Montreal Tunnel and Terminal Co., from its junction with the main line of the Canadian Northern Quebec Railway—near the Jacques Cartier Union Railway—is depressed through the new town of Mount Royal to the tunnel portal, where it passes under the C.P.R. belt line, about a mile from the latter's Outremont yard. From this point the tunnel goes down at a 0.6 per cent. grade, in an almost due easterly direction, to the McGill College grounds, where it curves into McGill College Avenue, which leads to the main passenger terminal, situated in the blocks between Cathcart and Lagauchetiere Streets and Ste. Monique and Mansfield Streets. The grades and elevations are such that this tunnel passes under St. Catharine Street, with ample room for a future rapid transit subway above it, and the tracks are able to be carried level through the station and over the lower town on the proposed viaduct, where a yard for light and perishable freight is contemplated, to connect with the proposed Harbor Commissioners' elevated and a possible bridge across the St. Lawrence River.

Two tracks will run both east and west from the main passenger station. The tunnel is something over three miles long, the viaduct about a mile long. The passenger station yard will be about a quarter of a mile long, with platforms over 1,000 feet long and an area of about nine acres. Local passenger stations will be situated down town and back of the mountain, as traffic demands. The main yard will be located near the Back River, where the electrical transfer yard will also be situated. There will also be a delivery yard in Mount Royal and an elevated yard in the commercial part of Montreal.

The designs for the Mount Royal tunnel are not yet completed, but it is probable that both twin tunnels and double track sections will be used, depending on the ground. Where the rock is of the proper character to permit it, the tunnel may be left unlined, although this cannot yet be determined. The minimum clearance has been limited to 16½ feet above the rail, but the standard tunnel clearance will be 17½ feet. The standard clearance in width is 6 feet off the centre line of track, which may be slightly reduced near the bottom as, for instance, at station platforms.

In the twin tunnel, centre walk-ways will be provided at about the level of the coach floors, and cross passages will be cut through the dividing wall, at intervals, for communication between the twin tubes. Refuge spaces are allowed for track men under the walk-ways. The ducts will be carried in the centre wall. The relation of the train cross section to the tube area will be approximately 50 per cent.

In the double track section the two tracks will be separated by the duct bench, which is the same height as the centhe walk ways in the twin tunnel, so that in case of a derailment one train cannot block both tracks.

The studies for electrification have not yet been completed, so that there is not much to be said on this subject. Owing to the climatic conditions outside the tunnel, it is improbable that a third rail will be used on the ground, which will probably force the adoption of some form of trolley. This means high voltage, either direct or alternating current. Great strides have been and are now being made in high voltage, direct current railway work and, until very careful and exhaustive studies have been completed, no decision can be made. This is important in the final design of tunnel cross sections, as the amount of head room for 10,000 volts alternating is quite different to that required for 1,500 volts direct current.

In the Mount Royal tunnel, where soft ground is encountered, a cap and post system of construction will probably be used, owing to the location of the rock surface; this running in general fairly near the roof line permits the full width timbering to be done without shifting posts, which rest directly on the rock. As fast as the roof excavation can be carried on in this manner, the arches will be built, so that the roof will be absolutely protected. After the arches are in, the lower excavation will be removed and arches underpinned, where necessary.

The plant for the Mount Royal tunnel will be quite complete. The compressor plants at each end consist of one direct connected cross compound unit of 2,200 cu. ft. per minute capacity, driven by a synchronous motor and three belt driven cross compound units of 1,100 cu. ft. per minute capacity, with induction motors. The power is three phase, 62½ cycles at 2,200 volts. Pumps, drills and some small motors are run by air. Most power used, however, is electrical. The drills used are the precussive type with the water attachment built largely of steel, to reduce their weight Horizontal bars are used to support the drills, and carriages are being made to handle the full drilling outfit for each heading.

The muck cars are 3 ft. gauge, very low and narrow. They are built with a 3 ft. wheel base, 18 in. wheels and springs on the axles. Both gasoline and electric locomotives will be used. Part of the tunnel muck will be crushed for concrete stone and ballast; part being used for fill and subfoundation work. The crushers are gyratory and roll hammer types, to give the desired grades, and both revolving and oscillating screens will be used over the bins.

The cages used at the shafts are of the counter balanced automatic dumping types, with electric hoists. These are designed for a capacity of about 800 cu. yds. per day.

The shops consist of a blacksmith shop, equipped with an air hammer, shears, punches, drill sharpening machinery and the usual forges; machine shops equipped with large and small lathes, a shaper, radius drills, saws, pipe machine, emery and grindstones, etc.; carpenters' shops, with band circular saws and drill repair and testing shops, as well as garage for the maintenance, storage and repairs of automobiles and auto trucks.

The method of excavation adopted in the Mount Royal tunnel is a bottom centre heading, with breakups at intervals where the full sized tunnel section will be developed. The heading is driven by the horizontal bar method. Later, a carriage and other auxiliary apparatus is expected to be used, as described under plant. At the breakups, jumbo timbers will be placed in the heading so that traffic can be maintained and the upper portion of the tunnel stoped down on the top of this and run directly into cars in the heading by gravity. As many of these breakups will be opened as are found necessary to keep up with the heading progress.

The firing is done electrically, but an effort is being made to get some special fuses with electric igniters, by which the cut may be fired electrically, at the same time igniting the time fuses of the relievers and line holes. This should give a better result than the ordinary time fuse method, without its accompanying risk, and will relieve the men from the necessity of going back into the smoke to load the later rounds.

In the Mount Royal tunnel, at present, the average progress at the west end is 20 ft. per day. In the east end, where the ground is rather bad, requiring timbering, and where no shooting is allowed at night, on account of public annoyance, the average progress for the last two months was 12 ft. per day. Heading 9 x 12 ft., 4 cu. yds. per foot. No drill carriage: precussive drills used with water attachment. 24 in. gauge temporary muck cars still in use.

THE RAT AND PUBLIC HEALTH.

By Lyman B. Jackes.

Doctors and health staticians have not as yet determined the position and rating of the rat on the list of disease conveyers and distributors. It is looked upon with suspicion and distrust by medical authorities in ocean ports and at other points of entrance for imports from foreign countries, but its exact facilities and adaptabilities for disease transmission are not understood.

Even aside from its supposed, and quite properly supposed, ability to transmit pathogenic organisms from district to district and from country to country, the rat is the source of immense annual losses in the industrial and agricultural worlds.

The word "rat" usually implies the brown rodent which we are accustomed to see in sewer approaches, barns, basements and stables, but this is but one member of the species Mus, which numbers about one hundred and fifty, all of which are known as rats or mice, according to the linear dimensions of the specimens.

The rat is indigenous to but a few portions of the earth, and this accounts for its non-mention in the Scriptures and other ancient writings with which we are acquainted, excepting the Chinese, and China would appear to be the starting point of rat migration and consequently for the introduction of diseases of a specific eastern nature into Europe. From Europe the pest only waited for the advent of systematic shipping to all quarters of the globe.

The brown rat's entrance into Europe was a comparatively recent occurrence, taking place about the year 1715, when an innumerable hord succeeded in swimming the Volga River, Russia, which is situate at the base of the Ural Mountains, in extreme Eastern European Russia.

This extensive migration of the rat is characteristic of the specie when pressed by hunger, and is an extremely dangerous aspect of the habits and tactics of the rodent.

Prior to the entrance of the brown rat into Europe, a smaller member of this order, known as the black rat, made extensive inroads to that continent about the year 1300. It may be a coincidence, but medical historians are not of that opinion, that the great Black Death which broke out in Europe a few years later and ravaged England from August, 1348, to Christmas, 1369. This loathsome affliction had carried off 66 per cent. of the population of Continental Europe before its introduction to England.

From historical writings, it is generally understood that this plague was of a bubonic nature, and as this is a disease, oriental in the strictest sense of the word, and has since been conveyed to European cities with frightful death lists resulting, there is probably strong grounds for such suspicion, but the most noted feature about this transmission is the well-grounded belief in the theory that it is introduced by rats carried in the holds and cargoes of ships coming from eastern ports. For this reason, during a recent outbreak of this loathsome disease in Continental Europe, all ships coming into British ports were held up before docking and a strong mixture of sulphur dioxide pumped into the hull in order that all rats might be suffocated.

If the rat were of an order that yielded easily and readily to death-dealing tactics, this would be a fairly good means of exterminating the pest, but such is not the case, for not only is the rat in itself difficult of killing, but the reproduction facilities of this animal are extraordinary in the extreme; one pair of rodents will on an average have about seventy-two young annually.

In the selection of food the rat is omnivorous and eggs, (which the rat can convey for very considerable distances unbroken) young birds of all varieties, fish, grains, cooked foods, small domestic animals, are all devoured with equal ease. Considering the facts connected with the rat and his properties of destruction, aside from his place in the medical health fields, the Canadian Government have decided that it would be beneficial to have this pest exterminated if at all possible, and with this end in view Mr. W. R. Reek, B.S.A., of the Ontario Agricultural College, Guelph, Ont., visited the Pasteur Institute in Paris in order that some experiments on rat extermination might be examined and witnessed.

The French scientists have been working for several months on a virus which would be contagiously deadly to rodents and harmless to other animals and man. The virus used for these experiments is of a bacteriological nature, and is contained in large bottles containing bouillon on which these organisms thrive. In actual use the contents of the bottle were diluted with water and scattered over oats and other foods which the rats were likely to eat. In a very short time a rat that has eaten of this grain dies suddenly of diseased throat, and this disease is transmitted with wonderful rapidity to other rats coming in contact with the dead one, and as it is a natural habit of the rat to maul and bite the body of a dead specimen of their own species, this would appear to be the great point in the application of the virus.

It is interesting to note that the French government is contemplating the enactment of a law which will enforce the usage of this material annually in every district. It has met with great success in underground railways, restaurants and

warehouses in London and Paris. In some of the banana plantations in Central America, where rodents have been attacking the roots, this virus has been used with satisfactory results.

Encouraged by the success which the French scientists have achieved, the Austrian government is going to carry on extensive experiments shortly, and there appears to be no reason to prevent its use in Canada.

BOOSTER PUMPS.*

By H. E. Cole.†

The determination of the proper presure to be maintained in any given waterworks system is often a very difficult one, and even when settled frequently results in general dissatisfaction for a large percentage of the consumers. It seems, therefore, that some time could profitably be spent in the study of ways and means of supplying the demand of those who are so located that the pressure of the system will not give satisfactory service.

There are at least three kinds of consumption requiring booster service:—

First—Tenants of tall buildings which are located on streets where the service is sufficient for ordinary requirements, but owing to the height of the building the normal pressure of the system is inadequate. In this class apparatus is usually installed by the owner of the building to boost and store a sufficient capacity for ordinary requirements.

Second—Small sections of a city's or town's population are frequently located on elevations higher than the reservoir or where the pressure is insufficient for their requirements. This is a condition which a great many companies have to face. It may be considered under seven heads.

(1) The number and class of consumers to be supplied determines the capacity of plant to be installed.

(2) The distribution of the population determines the location of the booster station and reservoir with reference to the main bringing in the supply. It furthermore makes necessary a careful study of first cost of large mains, low friction losses or of small mains, and necessary increase in pressure to overcome friction head.

(3) The presure to be maintained has a very important bearing, as it determines largely the character of the reservoir to be used as well as the type of pump to be installed.

(4) The importance of uninterrupted service has its effect on both the quality of apparatus and on the duplication of units as well as on the power employed and attendance.

(5) The amount of storage required usually determines the kind of reservoir which shall be used. If the pump is to operate automatically then the storage required may usually be very much smaller than otherwise. The determining factor, then, is the amount of storage required for fire protection or to supply the sections during the probable shutdown of the pumps or loss of power from any cause.

(6) The kind of power available materially affects the cost of operation and the adaptability of the power.

(a) If steam is the power used and coal the fuel the coal must usually be hauled a long distance, and at a high elevation steam must be kept up most of the time. An attendant must be present practically all the time the pump is in operation. The smoke nuisance must also be contended with.

(b) Natural gas for steam, when available, is far better than coal, as hauling is practically eliminated, and there is no smoke. In such cases, however, a small amount of coal should be kept in reserve and the boiler equipped to use both gas and coal in order to be prepared for a shortage of gas or other interruption of the supply. The necessity for a constant attendant, however, still remains.

(c) Natural gas when used in an internal combustion engine to drive a power pump makes one of the best powers for this service, as the fuel cost is usually the least and mechanical efficiency of equipment is relatively high. The chief disadvantages are frequent attention required, although far less than for steam—cannot be operated automatically without serious complications, although it is not only possible, but entirely practicable to make the pump operate automatically, as required, by keeping the engine running continually. Whenever gas engines are used it is good policy to provide gasoline attachments so that the engine could be operated on gasoline or other liquid fuel on very short notice.

(d) Gasoline or other distillate when used in an engine is to be recommended when gas or electricity is not available and where the amount of water to be pumped is small, as the fuel cost is usually high The advantage of this power is that, as a usual thing, the pumping unit can be started and operated at full capacity in a few minutes, ten minutes being a fair average. The objections are much the same as previously stated for gas, but there is the additional disadvantage of hauling and storage of the fuel and dangers of explosions in or near the buildings.

(e) Crude oil engines are rapidly being perfected and placed on the market which materially reduce the fuel cost, but require a little more time to start up than either the gas or gasoline engine.

(f) Electricity is very nearly an ideal power for this service, provided that an attractive rate can be obtained and the service is reliable for twenty-four hours each day.

A combination of any of the above powers may be used to advantage, depending upon the demands of the particular case.

(7) Accessibility by the attendant in charge materially affects the selection of equipment and cost of operation. If the amount of water to be pumped is only moderate, plant difficult of access, and electricity is available, it is desirable to keep cost of attention to a minimum; therefore make plant as nearly automatic as possible.

The location of the booster station depends entirely on local conditions. All things being equal, it should be located at the main reservoir from which the supply is taken. It is also preferable to have the pump so located that water will flow to it by gravity from the main reservoir. This insures the pump being primed at all times and eliminates the danger of getting air into the line.

When the section to be supplied is so situated that it is inadvisable to locate the booster pump at the reservoir, it should be located on a prominent main at a level which will positively assure a good supply on the level of pump intake.

A large vacuum chamber as well as an air chamber should be used on reciprocating pumps and a large air chamber would show good results even with a centrifugal or rotary pump.

In locating the booster plant attention should be given to the discharge. It is always preferably to use an independent line from pump to booster reservoir. Pulsations and noises are easily felt on lines from which service is given. Pulsations can be very materially reduced by the use of a large air chamber, depending entirely on the type

* Abstract of paper and discussion before the Central States Waterworks Association, September, 1912.

† Vice-President and Chief Engineer, Harris Pump Supply Co., Pittsburg, Penn

and apacity of the pump and the velocity of water in the line. Greater efficiency can be obtained from this air chamber if air can be supplied to the chamber to increase the relative proportion of air to water.

Noises can be reduced by the use of special gaskets or lead nipples. In some very bad cases it can be cured by using a short section of hose in the discharge between the pumps and the discharge main.

In both of these respects the advantage of using an elevated tank or standpipe or hydro-pneumatic pressure tank near the pump is very evident.

Third.—The third class of service is where the regular line pressure is sufficient for domestic consumption, but insufficient for proper fire protection to fulfil the requirements of the company's charter. The method of treatment, however, would be so nearly the same as for the second class that no additional suggestions will be given for this class.

Since the cost of attendance is one of the chief items of operating expense in a plant it is very desirable to reduce this expense to a minimum.

If an attendant is required all the time the pump is in operation it is generally good practice to install equipment of large capacity to reduce this item of expense. This means, however larger mains and larger storage capacity.

It would, therefore, seem desirable to keep line and reservoir cost down by pumping much of the day at a lower rate per hour, leaving only enough reserve to take care of ordinary increase in consumption or falling off of pump capacity and giving ample time for ordinary repairs. To do this and still keep down cost of attendance requires apparatus as nearly automatic as possible.

With steam equipment, an attendant is necessary on account of the use of boiler, but if steam is taken from some other source so that the pump is the only part requiring attention, then it should be the aim to provide a reliable source of lubrication and control speed of pump automatically. The simplest control is by a pressure regulator where the difference between starting and stopping pressures is fully 10 per cent. of the supplying pressure in the line and exclusive of the friction head. Where the line is a long one and the pump comes up to speed very rapidly it will be noticed that the pressure required to accelerate the water in the line from its state of rest to its regular velocity momentarily runs the pressure far above the maximum or stopping pressure of the system. Ordinarily this would cause the automatic control to act and stop the pump, and, this pressure being only temporary, the pump would again start, and the result would be a rapid alternation of stops and starts. This can be overcome by the use of a tank, of about 50 gal. capacity, to which pressure connection is attached. This connection should be made from discharge main to tank, so that the rate of flow from one to the other would be very small, namely, 1 or 2 gal. per min.; then with sufficient air compressed in top of tank so that it is ordinarily half full of water: it will be noticed that the pressure is very slow to respond to changes in the main line pressure and the temporary pressure due to starting is passed, and normal is restored before the tank shows any appreciable change.

Where the increase of pressure due to accelerating water in the line is high enough to endanger the pump or other equipment, a relief or safety valve should be installed to take care of the excessive pressure.

Where the difference in pressure between starting and stopping is less than 10 per cent., most regulators are unreliable, due to back lash and lost motion in the springs and other mechanisms. In such cases an artificial head can be produced, which, if the flow of water from the pump were constant, would cause sufficient difference in pressure to cause the controlling mechanism to operate, I believe, within 2½ per cent. of the shutting off pressure.

If this were carried out by the use of the tank described above and the introduction of sufficient friction in the discharge of pump to the discharge main, it would with regular line friction make the necessary difference required. This plan could not be successfully used with centrifugal pumps due to the varying capacity of pump under different conditions. In any case the power required for pumping would be increased by approximately the same amount as the increased pressure; still this amount would be very small compared with the saving effected.

The automatic control of steam pumps by float from the surface of the water in the reservoir is so complicated that circumstances would seldom justify it.

Electric pumps are by all means the easiest to operate automatically, first because an electric pump can be provided to operate continuously with practically no attention; and second, because electricity can be transmitted so easily. Stopping and starting can be easily performed by the rise and fall of water in a reservoir several miles away by means of a float and solenoid switches.

Pressure control is, however, always preferable, as the controlling apparatus is then under the same roof with the pump and the motor, and the danger from ice, storms, etc., which exists with floats, chains, etc., is eliminated.

Gas or engine automatic control is difficult, owing chiefly to the fact that most engines have to be started by some external power, and this is difficult to accomplish from a remote point. Partial operation, however, may be obtained by keeping the engine in continuous control, properly governed and well lubricated, and with an automatic pressure regulator, pressure being taken as previously described. This regulator would operate a control attached to level of a friction cut-off coupling so that the pump would, therefore, be started and stopped as desired. Float control would also be difficult by this method.

Another method of patrial control would be by connecting up the ignition circuit of the engine with a presure regulation or with a float switch. Then the engine could be stopped when the reservoir was filled, but could be started again only by an attendant. In this case a magneto should be used instead of batteries, for when the pressure fell to the starting point, it might short-circuit the batteries and run them down.

Discussion.—C. B. Salmon, of Beloit, Wis., said that experience with two or three booster installations, one at a mine in West Virginia had shown the electrical centrifugal pump to be easy to operate and very effective.

L. A. Tonkel, of Alliance, Ohio, gave substantially the following account of a booster station in his city:—

Our main pumping station is located about 240 ft. lower than the highest point in Alliance, and there have been days and days when everybody was sprinkling in extreme dry weather when the people at the highest point could not get any more than 10 lbs. pressure, although we had 240 lbs. pressure at the plant. The question arose of how to relieve that condition, which had existed for twenty years until people were getting tired of it. This hill was the finest location and best residence portion of Alliance, and they wanted water in those fine homes. I suggested years ago that we lay a 12-in. or 14-in. line from the town up to Mount Union, and put in a separate pump and pump to them direct just the same is if we were supplying two separate towns; that we have one pump for that hill and another for Alliance proper; but we found that would cost the city $300,000, and that was thought to be too much. So, instead of doing that, last spring we installed a booster pump just half way between the lowest point and the highest point.

At our lowest point we carry 125 to 130 lbs. at the pump house.

I start the pump at the booster station by electricity at 5 a.m., and at 7.30 p.m. it is shut down. I have a 12-in. valve between the inlet of this pump and the outlet. That gives them water in case of fire over night. When I start the booster pump I shut that valve off. When we get through with our improvements we are going to have two standpipes, one 60 ft. high, to supply the low pressure, and another one 100 ft. high, to supply the high pressure. When the standpipe is full on the high-pressure line the pump will shut itself down, and stay shut until we use 20 ft. After that the pump will start automatically. That is the way we have ours arranged. We ran it for one month for 3c. per kw.-hr.

Several who discussed the paper spoke favorably of electrically-driven pumps.

In response to numerous suggestions and requests Mr. Cole promised to supplement his paper with figures of costs and other data which would assist waterworks superintendents in deciding on the advantages of using booster pumps and aid them in choosing the best plan to meet local conditions.

RAILROAD EXPENDITURE WILL BE HEAVY

President E. J. Chamberlin, speaking of construction work on the Grand Trunk Pacific Railway, says the problem from now on to completion will be wholly one of labor. "We expect to have the line in operation for through traffic by the beginning of 1915. It is just a question of getting the requisite amount of labor into the territory in which we are building; it is simply a matter of displacing so many million tons of earth and getting enough men to do it expeditiously. At present we have about 10,000 men at work."

This year the Canadian Northern Railway will construct 978 miles of road to complete the Transcontinental line. This mileage includes 350 miles from the summit of the Rockies to Lytton, B.C., and 300 miles along the north shore of Lake Superior.

Work will be commenced by the Canadian Northern Railway between Toronto and Hamilton during the spring. The right of way between Hamilton and Niagara Falls is being secured.

The company hopes to finish the road from Toronto to Niagara at the same time as the Canadian Northern Railway transcontinental. Provision for through connection with New York, via an American line, and bridge connection at Niagara Falls, remains to be made.

Satisfactory headway is being made in completing the line between Toronto and Ottawa.

The line between Ottawa and Montreal will be ready next spring, and early summer should see a Canadian Northern Railway passenger service between Toronto and Montreal.

The Canadian Pacific Railway will shortly commence work on a four track system between Brandon and Fort William.

Forty million dollars will be expended in Montreal by the railways within the next two or three years. This large outlay is being undertaken by the Canadian Northern, the Grand Trunk, and the Canadian Pacific Railways, with the Canadian Northern assuming over half the expenditure. With the formal acceptance of the plans for the tunnelling of the mountain, the Canadian Northern Railway expect to commence operations early in the spring upon this task.

The Grand Trunk Railway expect to spend between $9,000,000 and $10,000,000 in the elevation of their tracks and in the building of a new station at Montreal.

The Canadian Pacific will apply for an act authorizing it to construct six new lines and extending time for completion of five others, already authorized.

It will also incorporate the Quebec, Portland and International Short Line, from La Patrie South to the International Boundary, following North River to Newport, Vt., to the main central in Eaton. This is supposed to be part of the plan for shortening the distance between Montreal and Portland over Main Central.

A new railway project is announced through application to incorporate the All Red Line Railway, from the Eastern boundary of the Province of Quebec westerly to Winnipeg, with branches to Ottawa, Port Arthur and Fort William.

CHANGES IN ONTARIO PUBLIC HEALTH ACT.

The important changes in public health legislation brought about by the new Public Health Act, as well as their likely effect on general conditions, in the estimation of Dr. J. W. McCullough, Provincial Medical Health Officer, are as follows:—

The supervision of sanitary conditions in the province by district officers of health (Sec. 13). Under this system the individual municipality will receive closer attention and first-hand advice from the district officers.

Local boards of health are retained, but the number of members reduced, and the medical officer of health is made a member—and the executive officer—of the board. Members of township boards are to receive $2 for each meeting attended. (Sec. 14-21). The medical officer of health, a qualified medical practitioner, to be appointed at a reasonable salary by the municipal council, and cannot be dismissed except for cause and with consent of the provincial board. He shall attend the annual conference of health officers and his expenses shall be borne by the municipality. (Sec. 35).

The work of local boards will, it is generally felt, be carried on in the better interests of public health, since the M.O.H. is a member, and since members in townships will be remunerated for attendance at meetings. By making the M.O.H. a permanent officer and paying him a reasonable salary, his services to the municipality will become more valuable, and interest in his duties will be still further increased by his association with officers in the same work at the annual conference each year.

Municipalities shall contract for the medical care of indigent sick (Sec. 52), and the M.O.H. may inspect lodging houses, etc., and if he deems a building unfit for human habitation, may placard it. (Sec. 86). The effect of these provisions will be obviously a step towards improved social conditions.

But the most important, owing to its far-reaching effects, is the legislation relating to waterworks and sewerage systems. Plans for the establishment and extension of any such system must be approved by the provincial board before any debentures can be issued to raise money for these purposes. In this way, the requirements of the board—as to proper treatment and disposal of the sewage, and the source of supply and process of purification of the water—must be carried out. The board may direct as to the maintenance, repairs and improvements of such system; and upon a certificate of necessity from the board, work may be undertaken in the interest of public health without a vote of the ratepayers. (Sec. 89-98). The final effect of this will mean the lessening of the pollution of our waterways, a safe supply of drinking water, and consequently a reduction in the number of cases of death from typhoid fever and other water-borne diseases.

WORKMEN'S COMPENSATION

BY C. W. I. WOODLAND.

While we have a so-called Workmen's Compensation for Injuries Act in force in Ontario, in reality it is not a compensation but rather an employers' liability act. There is a vast difference between the two. The term workmen's compensation as applied to the Ontario Act is a misnomer. In view of the wrong impression conveyed by the title, the employer of labor as a rule looks to the company in which he is insured for a great deal more than what his policy or contract calls for, and what he pays for. The employer pays for protection or to be indemnified "against loss from the liability imposed by law" upon him. He insures for his own benefit, and not for the benefit of his employees. Workmen's compensation insurance is a different proposition altogether. It is a form of accident insurance that calls for the payment to the injured workman of certain indemnities irrespective of how the accident occurred or who was to blame.

Under an up-to-date workmen's compensation law such defences as contributory negligence, common employment, assumption of risk, etc., etc., are done away with, and, subject to certain provisions and limitations, would entitle the injured employee, or in case of death his dependants, to compensation; the only proof of claim necessary being the fact that the employee met with an injury arising out of and in the course of his employment.

Under such a form of legislation the cost of insurance would be fixed by the insurance company commensurate with the obligations imposed upon the employer, and as the scale of indemnities would be provided for in the Act all the insurance company has to do is to make payments accordingly. This is an ideal condition and one that, provided the Act is carefully framed, practically does away with litigation, and from a humanitarian standpoint should meet with the cordial approbation of both employer and employee.

As I have already pointed out, in the province of Ontario to-day there is no such thing as a real workmen's compensation law. Under the present laws, the employer may not be held liable for accidents happening to his employees if

1. It can be shown that the accident was caused by contributory negligence on the part of the injured employee.
2. The accident was caused by a fellow-servant or workman in like employment.
3. The accident was incident to the injured man's employment and one over which he alone had control.

These are only a few defences to an action for damages. There are many others. Suffice it to say that when an employer delegates to a liability company his responsibility, or legal position, as it were, in respect to accidents happening to his employees, it is for the insurance company to decide whether to allow compensation or defend an action for damages, for and in the name of the employer, at the insurance company's expense. The employer pays a premium for indemnity against his legal liability only. He pays nothing for what is termed his moral liability. The insurance is for his protection and not for the benefit of his employees.

A workmen's compensation act, on the other hand, is for the benefit of the employees, and such being the case the employer would have to pay more for his insurance than under present conditions, but no doubt would cheerfully pay the extra premium knowing that his moral as well as his legal obligations would be as cheerfully cared for.

The tendency under present conditions is for the employer to expect a little more, and sometimes a great deal more than what he pays for. It often happens that when an employee is injured the humanitarian and generous employer sends the injured employee to the hospital, guarantees the payment of hospital, doctors', and nurses' bills, and pays the injured employee's wages during the period of his disability—this aside from the conditions of insurance—and then expects the liability company to reimburse him for his outlay, even though it may subsequently have to defend an action for damages brought by the employee.

The old stock argument of the policyholder who assumes the functions of the insurance company upon his own responsibility, notwithstanding the fact that the contract or policy expressly stipulates that

> "The assured shall not voluntarily assume any liability, nor shall the assured, without the written consent of the corporation previously given, incur any expense or settle any claim except at his own cost, etc., etc."

is that "it pays better to settle than to have to fight a lawsuit," overlooks the fact that his is not the only case the liability company is dealing with, and that thousands of claims are constantly in the course of adjustment.

It will be a progressive move when the province of Ontario adopts an up-to-date workmen's compensation for injuries act. The cost for insurance would then necessarily be more than it is to-day. The insurance company carrying a risk would have something definite to go by in the matter of paying compensation. Litigation would be a thing of the past, and instead of the iniquitous, or I should say the ubiquitous, lawyer getting his share of the spoils as he does to-day, the full indemnity would be paid direct to the injured employee. Until this new order of things comes about the employer of labor carrying liability insurance should recognize the difference in conditions and keep in view the fact that the insurance he is now carrying is for his protection, and not in any sense of the word for the benefit of his employees.

PAPER MANUFACTURING IN CANADA.

Canada has certainly made strides during the past year or so in paper manufacturing. Mr. E. B. Biggar, of Toronto, a Toronto pulp and paper authority, says that Canada's growth of the two industries has exceeded that of any single nation in the world since wood became a raw material for paper making. A remarkable feature of this development has been the number and capacity of the new mills devoted to news-print, these mills representing the last word in mill designing, in capacity of paper machines and in rapidity of production. The following is a list of these news-print paper mills:—

	Daily capacity in tons of paper.
Powell River Company, B.C.	200
Dryden Timber and Power Company, Ont.	40
Spanish River Pulp and Paper Mills, Ontario	155
Ontario Pulp and Paper Company, Sturgeon Falls, Ont.	45
Sault Ste. Marie Mill, Ontario	200
International Falls Mill, Fort Frances, Ont.	100
Ontario Paper Company, Thorold	120
Price Brothers and Company, Jonqueires, Que.	150
Edwin Crabtree and Sons, Quebec	20
Smaller new mills and additions to old mills, say	170
	1,200

Thus there has been an increase of 1,200 tons per day in news-print. It is not strictly correct to say that this is the work of a calendar year, for some of these new mills were

started in the latter part of 1911, while two of them are not yet finished and will not be in operation till the middle of 1913, but the increase which can be credited to 1912 will still be about a thousand tons per day.

STORES OF VANCOUVER ISLAND

BY ERNEST McGAFFEY.

As it is axiomatical that cities thrive as the surrounding country develops, so it follows that the railway and trunk road policy inaugurated by Sir Richard McBride and the provincial government has been of vital importance to Vancouver Island. The Premier of British Columbia has stimulated development in these lines so greatly that it is no exaggeration to say that railways and roads head the list of the factors leading to progress all over the island.

The advent of the Canadian Northern Railway not only meant the opening up of large areas of virgin territory, but it carried with it an immediate stimulus to the halibut and whale fisheries, with important capitalization and extension of these industries. It also made accessible vast timber tracts, iron deposits, etc.

The aggressive activities of the Canadian Pacific Railway through its island line of the Esquimault and Nanaimo Railways promises to revolutionize conditions along the east coast of Vancouver Island, and particularly along that portion of it represented in the rich Comax and Courtenay country, a district not surpassed on the island for excellence as a dairying and mixed farming centre. The entry of this line into the Alberni Valley and to Alberni and Port Alberni was also of great importance, as opening up a magnificent timber belt, and connecting with the west coast by way of the Alberni Canal. Coal, copper, and fisheries are also tributary to the Alberni district, and general tourist traffic has been increased by this branch.

All along the Alberni Canal the various communities as Uchucklesit, Bamfield, Sechart, Ucluelet, Clayoquot, and other settlements, have felt the impetus afforded by the incoming of the Esquimault and Nanaimo Railway to the Alberni district.

Development along the line of the Esquimault and Nanaimo Railway from Victoria to Nanaimo is shown at every point. Probably the most apparent results are at Duncan, Ladysmith, and Nanaimo. At Duncan, in the Cowichan Valley, much progress has been made recently in this model farming community.

At Ladysmith, there are from 3,500 or 4,000 people, and its future as a manufacturing and shipping point is assured, with its fine natural harbor, rail facilities, and adjacent possibilities as a fruit-growing district.

Nanaimo is awakening to its possibilities. Its pay-roll runs into the hundreds of thousands from the near-by coal mines, large sawmilling interests and fisheries. Other interests include stone quarries, timber, fisheries, manufactures, and an adjoining district of splendid possibilities for mixed farming, truck gardening, fruit growing, poultry-raising and stock-farming, and fine shipping facilities. The city has now about ten to twelve thousand population, and is increasing rapidly in numbers.

Cumberland is also evidence of Vancouver Island's advancement, and with the Esquimault and Nanaimo Railway's extension, it will have connection with this line through the present railways running from Cumberland to Union Bay. As the central city of a coal-mining district, Cumberland will grow. Fine water-power on the Courtenay River and lumbering districts are near it.

Comox, Sidney, Courtenay, Chemainus, and other towns on the east coast, Port Alberni and Alberni show steady growth. Port Alberni is the terminus of the Esquimault and Nanaimo Railway, and Alberni is only two miles further inland. Both towns have good harbors; they will merge in time.

Victoria is one of the leading ports of the Dominion. Her new outer harbor, to be built by the Dominion government, requires an initial outlay of $1,500,000, and will take $10,000,000 to complete it and the inner harbor improvements.

Victoria's harbor is practically free from fog, and easy of access and departure. Freight and passenger traffic has doubled in the past three years; in 1911 over 5,500 vessels berthed in its harbors. It is the coming terminal of five transcontinental railway systems, viz., Canadian Pacific Railway, Canadian Northern Railway, Grand Trunk Pacific, and Great Northern and Great Eastern Railway. As a manufacturing, commercial and residential city, its future is bright, and its tributary territory contains valuable natural resources, including the following:—

A supply of merchantable timber equivalent to about a billion feet per year for a hundred years. Then there is 1,500,000 acres coal deposit controlled by one corporation. Iron is found at Sooke, Bugaboo Creek, Sarita, Nootka, Campbell River, Quatsino and other points.

Vancouver Island produced, according to the Tyee Copper Company manager's estimate, "about one-half of all the copper that has come from the entire Pacific coastal district during the five years ending April, 1910. There is five hundred thousand horse-power of water-power available, though present development is less than 50,000 horse-power

There is a supply of marble, brick clay, fire clay, gold and silver, quicksilver, talc, and various other metals and natural products, sand, gravel and building materials.

There are two cement plants, one fully equipped and running, and the other soon to be ready.

Agriculture, horticulture, fruit and berry growing, poultry-raising and live-stock breeding are profitable and being developed.

Valuable fisheries are also among the island's resources; whale fishing is carried on at Sechart and Kyuquot, controlled by Messrs. Mackenzie and Mann. Salmon is abundant. Halibut is caught in large quantities on the west coast. At Nanaimo the large herring industry is under the control of Japanese.

BIG ORDER FOR RAILWAY EQUIPMENT.

The past year was an unusually busy one for the rail mills, locomotive works and car foundries. The Canadian Pacific, Grand Trunk, Grand Trunk Pacific and Canadian Northern Railways gave orders during 1912 for 727 new locomotives and 43,164 freight cars. These orders will keep the car and foundry companies busy well into the current year. The figures may be summarized as follows:—

Engines or cars ordered, 1912.	Canadian Pacific Railway.	Grand Trunk Railway.	Canadian Northern Railway.
Passenger	414	.....	150
Freight	29,442	7,650	6,072
Miscellaneous	194	.....	.....
Total	30,524	7,790	6,336
Locomotives	473	140	114

It is estimated that there were at least 20,000 more cars and 400 more locomotives available last fall than in the previous year.

The Canadian railways expended last season about $4,000,000 on improvements and enlargements of terminals.

COEFFICIENT OF SLIDING FRICTION OF CONCRETE ON CONCRETE.*

By Frank P. McKibben.†

In well designed masonry structures reliance is placed on something besides friction to resist sliding tendencies; but unfortunately not all structures can be classed in the above category, and a knowledge of the value of frictional resistance is necessary. In concrete or stone masonry dams, both in the structure itself and at the base, the horizontal pressure should be resisted not by friction alone but by shearing. Clearly this can be accomplished by bonding the masonry—stepping it at the base and interlocking in the body. However, to provide against errors in construction every structure in which there is a tendency to slide on any plane must be proportioned to have a proper factor of safety against sliding on that plane.

The importance of this precaution is only too well illustrated in several recorded failures of masonry structures. It is further emphasized by the fact that in an ordinary masonry dam with a vertical upstream face and a curved downstream face, designed to keep the line of resistance just within the middle third, the factor of safety against sliding on horizontal planes, considering friction only, is about 1.1 to 1.5 at most. And this condition obtains where no upward pressure is assumed to act at these planes. When the upward pressure acts the factors on the same cross-section are less because the resultant normal pressures are less, while the tangential components remain unchanged.

If, as is sometimes the case through lack of supervision, such a dam be built with horizontal joints or with a horizontal base, the factor of safety is altogether too small. The question of what coefficients of sliding friction the above factors of 1.1 to 1.5 are based upon is then a very pertinent one.

A search of experimental data on the frictional resistance of masonry reveals the fact that as far as can be determined all tests have been made on separately moulded specimens, and practically nothing has been done toward determining the resistance of concrete to sliding on concrete with the upper body moulded directly on the lower. If two cubes of concrete be separately made and then superposed for testing, the resistance to motion can be called the friction of starting and the resistance during motion the friction of motion; but if one cube be moulded directly on another and later tested in that position the resistance to sliding is at first due to adhesion, and during motion the resistance is, of course, friction of motion. All published friction coefficients are seemingly those of bodies without adhesion.

It further appears that the coefficients of friction frequently recommended for masonry structures, namely, from 0.60 to 0.75, are those at which sliding actually starts—not the coefficients modified by a factor of safety but the actual values which cause the motion to begin. Assuming that the coefficient necessary just to start motion of concrete on concrete separately moulded is 0.66, and that a dam is built with that same relation existing between the horizontal sliding force and the resultant vertical component on the horizontal joint, then but one factor of safety against sliding exists at that joint, if the surfaces between the experimental blocks are the same as those in the dam and adhesion in the latter is neglected. A factor of one really means no factor at all; it means that the structure is just on the point of moving. If, on account of the upper mass of concrete in the dam being laid directly on the lower, adhesion is considered, then the factor of safety in the above hypothetical case is probably greater than one, possibly 1.5 or 2. The coefficient of friction must be considered an ultimate or breaking coefficient, and clearly the working factor should be considerably less than this. Its value should be found from the breaking coefficient by dividing the latter by a real factor of safety.

The only experimental determinations of frictional resistance of stone are those of Morin, made between 1813 and 1834, and of Trautwine. Morin's experiments were made on dry blocks of soft oölitic limestone sliding on the same material, the contact areas varying from 0.5 sq. ft. to 0.86 sq. ft., with total normal pressures ranging from 310 to 1,275 lb. For this material he gives 0.74 and 0.64 for co-efficients of friction starting and of maintaining motion respectively. Trautwine made a few experiments, but none of them was on concrete. The coefficient of friction for masonry is therefore based on stone, and nothing has been published regarding concrete.

Recently in the Fritz Laboratory some experiments were made by Messrs. S. C. Peters and I. A. St. John, and the following is a summary of the work accomplished up to the present time:—

Some 12-in. concrete cubes were separately moulded in wooden forms, and, after curing, the coefficients of sliding friction were determined by placing one cube upon another and finding the force necessary to slide the upper along the lower. The accompanying table shows details of the tests for low normal pressures.

The apparatus used in testing consisted of a bell-crank lever, the vertical arm of which was connected by a horizontal yoke to the upper cube. On the horizontal arm of the bell-crank was a vessel into which fine shot was carefully poured till motion took place. The forces determined in this manner, together with the pull due to the weight of the bell-crank, are those necessary to start the upper cubes. As the total motion of the cube was only a few inches no distinction could be made between the starting forces and those necessary to maintain motion. In some tests the normal force was increased by adding standard 50-lb. weights on the upper cube.

Results of Tests to Determine the Coefficient of Sliding Friction of Concrete on Concrete.

No. of Tests.	Total weight moved, lb.	Total pulling force, lb.	Friction coefficient per cent.	Condition of surface
	Mixture, 1:2:4 Concrete.			
1 to 6	146.35	105.72	72.2	Dry
7 to 14	147.81	101.09	68.4	Wet
15 to 20	148.75	99.26	66.7a	Dry
	Mixture, 1:3:6 Concrete.			
22 to 25	147.5	101.11	68.6a	Dry
26 to 28	147.5	100.05	67.8	Wet
29	197.5	140.63	71.2a	Dry
30	197.5	114.27	57.9	"
31 to 32	197.5	138.61	70.0	"
33 to 34	247.5	175.63	70.9a	"
35	297.5	176.63	59.4a	"
36	347.5	237.95	68.4a	"
37	397.5	251.27	63.2a	"
38	447.5	296.27	66.2a	"
39	497.5	321.63	64.6a	"
40	547.5	366.27	66.9a	"
41	597.5	377.95	63.3a	"
42	647.5	395.27	61.0	
43	697.5	423.27	60.7	

Average coefficient 29-43 65.6. Average of all tests, 67.7.
a Indicates surface cleaned.

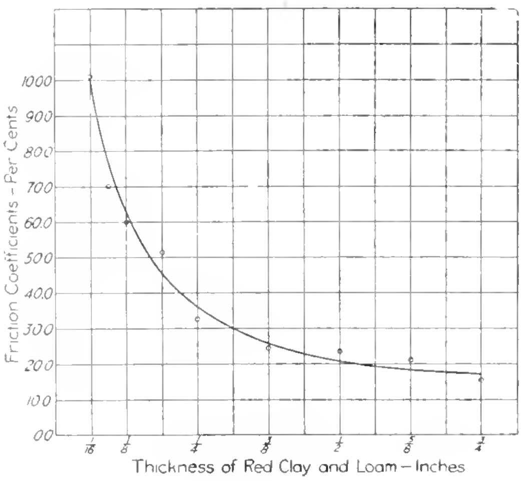
---

* Abstract of paper delivered before National Association of Cement Users.

† Professor of Civil Engineering, Lehigh Valley

The average coefficient of all tests shown in the table is 67.7 per cent. There is no great difference between the values obtained for 1:2:4 and 1:3:6 concrete; but the former are slightly larger. Wetting the contact surface seems to lower the coefficients but very little. In tests numbered 29 and 30 the average coefficients are 71.2 and 57.9 per cent. respectively; the conditions in the two series being the same except that in the first the contact surfaces were cleaned after each test by removing the dust formed by grinding while in the latter the dust was allowed to remain. A similar effect was shown in other tests. From test 33 to test 43 the total weight moved was gradually increased from 247.5 to 697.5 lb., and this was accompanied by a decrease in the coefficient from 70.5 to 60.7 per cent. Since the surfaces were cleaned after each test this decrease was probably due to greater smoothness caused by rubbing and not to any change in coefficient resulting from increased pressures, except in so far as the increased pressures may increase the abrasion.

Another interesting test, though not conclusive, because it was only one test, was performed by moulding one cube directly on another that had previously hardened. After allowing the two to set for 20 days the sliding test was made



Curve of Friction Coefficient.

with the result that a total pulling force of 200.95 lb. was necessary to slide the upper cube, weighing 147 lb. In this case the adhesion caused the coefficient to reach 37 per cent. More tests of this character are now under consideration, as are some to determine the effect of laitance.

Of interest also is a set of experiments to find the coefficient of two cubes between which was placed a ¾-in. layer of wet red clay and loam. From this thickness the layer was gradually diminished till it reached about 1/16 in., the coefficient being found at each thickness. The accompanying curve showing thickness of clay and corresponding coefficients indicates that with a ¾-in. layer the coefficient was 15.3 per cent., while for the thinnest layer the coefficient was 101.0 per cent.

As all of the 42 tests recorded in the table were made on separately moulded cubes superposed on each other in pairs, the conclusion reached for this case is that for ordinary concrete the average coefficient for sliding friction is 67.7 per cent., corresponding to an angle of friction of about 34 deg. The minimum value obtained was 57.9 per cent. and the maximum was 79.4 per cent. It should be remembered that the values here given are those which cause motion and before being used in design should have a proper factor of safety applied to them. A determination of the effect of moulding concrete in contact, of the presence of laitance, and of increased normal pressures will throw further light on this question of frictional resistance.

SMOKE PREVENTION WORK IN CHICAGO.

The city of Chicago has for a number of years through its Smoke Department given considerable study to proper furnace design with reference to smoke production and has achieved much success through advising plant owners as to advisable furnace changes. The department has realized, however, that the smoke ordinance as interpreted was not elastic enough to take in all classes of offenders, and it, therefore, instituted in the spring of 1912 an investigation involving a great many chart readings to be used in comparing different plants in the same industry. An appeal could thus be made to the civic pride of the owners of plants which, even if not violating the law, were nevertheless producing large quantities of smoke. The plan was described by Mr. Osborn Monnett, smoke inspector, before the Western Society of Engineers, Nov. 4, 1912.

The ordinance, Mr. Monnett pointed out, says that only dense smoke constitutes a violation. Dense smoke, according to the Ringlemann method of reading, is No. 3 smoke or worse. If a plant makes a continuous No. 2 smoke the total amount of smoke made in a 10-hour run would be enormous, yet the plant would easily run within the smoke ordinance and the matter could not be taken into court.

The smoke density of a plant running a continuous No. 2 smoke on the Ringlemann chart would be 40 per cent., yet another stack might violate the smoke ordinance in seven minutes of continuous dense smoke, and be absolutely clear for the rest of the hour or the rest of the day, and the smoke density for the day would not figure more than 2 or 3 per cent., yet the second offender would be liable to prosecution while the first offender, who was really making the most smoke, would go entirely free.

According to the technical interpretation, the Ringlemann chart reading consists in reading the smoke density of a stack every 15 seconds for the period under observation; in this way a very close record of the behavior of the stack is obtained. The method of figuring the data on a chart of this kind is as follows. The number of observations of Nos 1, 2, 3, 4 and 5 smoke are tabulated and reduced to smoke units as follows:

70 units of No. 1 smoke =	70
34 units of No. 2 smoke =	68
100 units of No. 3 smoke =	300
29 units of No. 4 smoke =	116
146 units of No. 5 smoke =	730
Total	1,284

As the readings were taken every 15 seconds, this figure 1,284 divided by 4 gives the smoke units on a per minute basis, and as one smoke unit represents a density of 20 per cent., the calculation for the per cent. of density for the stack would be

$$321 \times 0.20 \times 100 \div 170 = 37.7 \text{ per cent.}$$

170 in this case being the number of minutes the stack was under observation.

The Ringlemann chart reading shows not only the per cent. density of the smoke for the day, which is in fact the measure of the desirability or undesirability of the stack, but it also gives the number of violations per hour of the stack, if any. Readings of this nature taken in the past 6 months have been classified according to industries and charted for closer study. A standard of 2 per cent. density for a day's observation was taken to represent good performance, anything under 2 per cent. being considered exceptionally good and anything above 2 per cent. being considered subject to criticism. This is entirely independent and separate of any consideration of whether or not a stack actually violated the ordinance.

The method of making use of the tabulated information is as follows: In working on, for instance, the clubs of the city, a copy of the chart is shown to the offender at the foot of the list and an appeal to his civic pride is made, which in most cases is sufficient to get satisfactory action.

In approaching an industry such as a piano factory for instance, which is making too much smoke, the department first picks out a factory in the same line of business which has as nearly as possible the same boiler equipment and lays the facts before the offending corporation, in effect, for instance, that whereas their piano factory is running, say, 18 per cent. or 19 per cent. smoke density on a day's observation, the piano factory across the street, a competitor of theirs, is running inside of 0.5 of 1 per cent. density, and that from the smoke department's standpoint there is no reason why their piano factory cannot be run as clean as another piano factory, provided they will put their plant in proper shape. This argument seldom fails to get the desired results without suit or threat of suit.

The information contained in the tabulated list is of great value, Mr. Monnett stated, in combating claims of plant owners when they make the assertion that their plants do not smoke. One of the most common statements made to the department is that the owners do not believe the plant is smoking and that, compared with a similar line of industry, their stack is much better than their competitors. In one instance a brewery manager made this statement, and if it had not been for the tabulated information on file it would have been very difficult to convince this party that he was not right. When this manager realized that of 44 breweries in the city, 35 or 36 of them were making less smoke than he was, he capitulated, and in the near future his entire boiler plant will be rebuilt in the effort to get to the top of the list.

The smoke department is holding every new plant built in the city of Chicago to a standard of 2 per cent. smoke density on 10 hours' observation before issuing a Certificate of Operation, as provided for in the ordinance. That this standard is not unreasonable, even in the hand-fired installations, may be realized when it is stated that with approximately 250 new plants which have been installed under permit since Jan. 1, 1912, practically all of them that have been put in operation are able to show this low density on a Ringlemann chart. Those which do not show this density are studied with a view to improving conditions, and no Certificate of operation is issued until this standard is reached. For the purpose of keeping track of this work, a form of Certificate of Operation Release has been prepared. This certificate, after giving the type of boiler and furnace, provides for a statement by the engineer of the district that he has personally seen the furnaces in operation, carrying their regular working load, and that he knows personally that the plant can be operated inside the ordinance. To this form is attached a Ringlemann chart reading showing a day's operation with 2 per cent. density or less; the certificate is then issued, a copy of the Ringlemann chart going to the plant owner with a statement that this is the standard which the smoke department will expect the plant to maintain in the future. As the Ringlemann chart is taken with the full knowledge of the operators, it really sets a mark for them to maintain, and any deviation from it is quickly noticed by the smoke department and followed up until the plant is clean at all times.

The same plan of using the good performance of one company to spur others to better work is being pursued in the railroad campaign. In the fall of 1910, series of railroad readings were made showing the smoke conditions at the various railroad centres, and a table showing the smoke standing of the railroads was prepared. In the fall of 1911 a similar set of figures was prepared. It soon became evident that there was an intense rivalry among the various railroads in their efforts to be at the top of the list. This has been taken advantage of with good effect by the smoke department. It has long been realized that railroad smoke appeared heavier in summer than during the cold weather, but it was not known how much the weather affected smoke densities. Taking the smoke readings of the fall of 1911 as a criterion, and assuming the same effort on the part of the railroads to keep down smoke, the summer readings of 1912 show that there is approximately 100 per cent. difference in the smoke density in the summer over the winter months.

The railroad readings are furnished in more detail than has been presented before, as it has been found that the more information the department can convey to the railroads the better the results. For instance, by giving the smoke densities for the various locations, a railroad may find that its per cent. density at a certain point is very satisfactory, whereas at another railroad centre it is not at all satisfactory. By analyzing these smoke density reports for the various localities, a railroad is enabled to determine the points where their engines need special attention and to discover why it is that they cannot have a uniform smoke density throughout the city. Theoretically, if one railroad is inside of 5 per cent. density there is no reason why all the rest of them should not be, but practically it does not seem to work out in this way; there is a difference in organization, difference in methods, difference in service performed, and difference in condition of equipment, which seem to have an immense amount of influence on the smoke densities of the various roads. However, it seems logical, Mr. Monnett believes, that if uniform methods of enforcing the anti-smoke rules were adopted by all the roads, and if standard equipment in various classes of service was provided, that uniform results can be obtained throughout the city and the smoke kept down to the minimum.

MUST INSTALL BRICK PLANTS

Lessees of Western clay lands in future must make bricks as well as stock sales. An order-in-council has been issued regarding the leasing and administration of lands containing limestone, granite, slate, marble, gypsum, marl, gravel, sand or any building stone, in the provinces of Manitoba, Saskatchewan and Alberta, and the Northwest Territories; within twenty miles on either side of the main line of the Canadian Pacific Railway in the province of British Columbia, and in the tract of three and one-half million acres acquired by the Government of the Dominion from the province of British Columbia. The order amends the existing regulation so as to include the leasing of Dominion lands containing deposits of clay, subject, however, to the following additional conditions:—

1. The lessee of a clay location shall, within two years from the date of the lease, erect upon the lands described therein, or on lands acceptable to the Minister, a plant suitable for the manufacture of brick or other clay products, and he shall, within the same period, furnish evidence, supported by affidavit, showing the character and value of the plant installed and the date of its installation. If the required plant is not installed within the time specified, and if evidence of its installation is not furnished within the same time, the lease shall be subject to cancellation in the discretion of the Minister. Provided, however, that the Minister shall not require that the value of the plant so installed shall exceed the sum of $10,000.

2. The lessee of a city location shall, during each year of the term of the lease after the second year, manufacture

from his leasehold and produce ready for shipment not less than 100,000 bricks, or their equivalent in some other form of clay products, to the satisfaction of the Minister. If during any year, after the second year of the term of the lease, the lessee fails to furnish satisfactory evidence of his having done so, the lease shall be subject to immediate cancellation in the discretion of the Minister.

UNITED STATES STEEL CORPORATION IN CANADA

The fact that the United States Steel Corporation has for several years been acquiring real estate at Sandwich, Ontario, led to the theory that at some time or another that corporation would establish a plant there. The time has apparently arrived, as, according to a dispatch from New York at a meeting of the directors of the United States Steel Corporation it was decided to build a new plant at Sandwich, costing approximately $20,000,000, to manufacture practically all classes of steel. The company has about 1,500 acres of land, with 1½ miles of waterfront opposite Detroit, Michigan. The corporation will probably erect a number of blast furnaces in addition to wire, rail, structural and bar mills. Tinplate and tube works may also be erected. All the details have not yet been arranged but it is likely that a bond issue to meet part of the cost of construction of the new plant will be negotiated. No date has been set for the beginning of construction, but work will probably be started as soon as all arrangements have been made. To operate the plant, a new subsidiary of the United States Steel Corporation will be organized in Canada.

Mr. J. H. Plummer, president of the Dominion Steel Corporation, discussing the above announcement, said:—

"There is room for us all in Canada, and it is certainly better from the general standpoint that the trade should be in the hands of strong people. The Dominion Steel Corporation is not afraid of competition from the United States Steel Trust or anybody else."

Mr. J. R. Wilson, a Montreal director of the Dominion Steel Corporation, and also identified with the Canadian Steel Foundries, said: "One may draw his own conclusions as regards competition. For instance, in the buying of ore the Dominion Steel Company pays about $1.75 per ton, while the United States Company pay $3 to $4 for the same, and yet the United States company, with their vast knowledge, experience and money, can and are selling their finished product at $5 per ton lower than any other company, even at the recent advance of steel prices.

"Though I believe the United States Steel Corporation will do us no material harm, it is true there will be a great deal sharper competition immediately the plant begins to operate at Sandwich. Any competition will be felt largely in the West, where the country is growing and the demand is large, but in the East I do not believe the competition will be felt for the present."

In the annual number of The Monetary Times, published this week, Mr. Thomas Cantley, of the Nova Scotia Steel and Coal Company, complains of the extent to which Canada was utilized last year as a dumping market, illustrated by the fact that of the entire export of pig iron by the United States in 1912, 90 per cent. was thrown into Canada, while of finished products an enormous tonnage was disposed of in the same market at prices in many instances 20 to 25 per cent. below that at which they were selling raw pig iron five years previously.

Canadian steel manufacturers are anticipating early revision of the tariff. Any changes made will be announced in the budget speech which is not due, however, for several months yet. Mr. Cantley says that notwithstanding the enormous home demand, coupled with good trade and high prices in Great Britain, Germany and other European countries, owing to the ill judged action of the United States producers last year and the inadequate customs tariff applying to a considerable percentage of steel products imported from the United States, Canadian mills and forges find their earnings much less than they should have been under normal conditions.

Sandwich, where the United States Steel Corporation will establish its Canadian plant, is the capital of Essex County, Ontario, on the Detroit River. About two miles northeast of the town is Windsor, the terminus of the great western division of the Grand Trunk Railway. The town is on the line of the Sandwich, Windsor and Amherstburg Electric Railway and has a population of approximately 2,300.

LAST YEAR'S GOLD PRODUCTION

The world's production of gold during 1912 was $5,500,000 greater than in 1911, the total having been $465,000,000, according to a preliminary estimate of Mr. George E. Roberts, director of the United States mint. Gold production in the United States amounted to $91,685,168, compared with $96,890,000 in 1911. California led with $19,988,486; Colorado was second with $18,791,710; Alaska third with $17,398,946; Nevada fourth with $13,331,680, and South Dakota fifth with $7,795,680.

Of the world's production the Transvaal and Rhodesia made a gain of about $20,000,000, and Canada gained nearly $3,000,000. The United States, Mexico and Australasia lost about $16,000,000, and in the rest of the world the production was about what it was last year. Since 1908, when the production of gold in the world was $442,475,000, the annual increase has been comparatively small.

The mint service of the United States during the year sold $38,000,000 worth of gold bars for consumption in the arts in this country and Canada, as against $35,000,000 in 1911. The net consumption of new gold, including coin for such uses, in the United States and Canada was about $35,000,000, and in the world, excluding Asia, probably between $100,000,000 and $115,000,000.

The absorption of gold by India, which has been attracting attention for several years, was again a noteworthy feature. The net imports of India in 1909 were approximately $50,000,000; in 1910, $90,000,000; in 1911, $116,000,000, and in 1912 approximately $140,000,000. The movement of silver to India also continues to be very heavy. The importations of silver, in ounces, during 1912 have been exceeded only once in the history of India in 1906.

The increase of gold in the monetary stock of the United States in 1912 was approximately $90,000,000. The gold holdings of the United States Treasury increased about $70,000,000, chiefly in bullion, represented in the circulation by certificates.

The production of silver in the United States during 1912 amounted to 62,369,974 fine ounces compared with 60,399,400 fine ounces in 1911, the chief gains in production having been made in Utah and Colorado. Nevada ranked first in production with 13,042,118 fine ounces, Utah second with 12,795,072 ounces, Montana third with 12,338,589 ounces, Colorado fourth with 8,350,316 ounces, and Idaho fifth with 7,703,121 ounces.

There is talk of double tracking the Temiskaming and Northern Ontario Railway.

NEW COMPANIES IN ENGINEERING AND OPERATING FIELDS.

The new White companies held their organizing meetings on January 6th, and announced the following boards of directors and officers:—

Of The J. G. White Engineering Corporation the directors are: Harry Bronner, of Hallgarten & Company; James Brown, of Brown Brothers & Company; F. Q. Brown, of Redmond & Company; Douglas Campbell, of Campbell, Harding & Pratt; Geo. C. Clark, Jr., of Clark, Dodge & Company; Bayard Dominick, Jr., of Dominick & Dominick; A. G. Hodenpyl, of Hodenpyl, Hardy & Company; T. W. Lamont, of J. P. Morgan & Company; Capt. Marion McMillan, of Emerson McMillan & Company; J. H. Pardee, president The J. G. White Management Corporation; E. N. Potter, of Potter, Choate & Prentice; Frederick H. Reed, vice-president J. G. White & Cómpany, Inc.; Chas. H. Sabin, vice-president Guaranty Trust Company; Frederic Strauss, of J. & W. Seligman & Company; Moses Taylor, of Kean, Taylor & Company; George H. Walbridge, of Bonbright & Company; E. N. Chilson, and C. E. Bailey. And the officers are J. G. White, chairman finance committee; Gano Dunn, president; E. G. Williams, A. S. Crane, H. A. Lardner, vice-presidents; H. S. Collette, secretary, and R. B. Marchant, treasurer.

During the year ending October 1, 1912, the departments of J. G. White & Company, Inc., which have just been organized into the above engineering company, were at work on contracts aggregating in cost over $28,000,000, and on appraisals and reports upon properties aggregating over $400,000,000. Many different types of engineering service were required throughout thirty different States and Canada, among them the complete rehabilitation of several public service properties, the construction and equipment of two high-speed interurban electric railways, one of which is eighty-four miles long and includes difficult tunnel and canyon construction in California. There was also engineering for the drainage of 118,000 acres in Florida, and the design and construction of a 124-mile 12-inch natural gas pipe line, which line is noteworthy because it is the first in California, and because it is to operate at a pressure of 450 pounds per square inch, the highest ever yet employed.

The hydro-electric developments include some of the most important in the United States, such as the Big Sandy, at the foot of Mount Hood in Oregon; the Deerfield, an important tributary of the Connecticut River; the Savannah River development near Augusta, Georgia; the Broad River near Columbia, South Carolina, and the Ocoee in the mountains of eastern Tennessee. In addition to these, there are the San Joaquin development in California, and that of the Beauharnois, on the Saint Lawrence in Canada. The aggregate capacity of these water powers is approximately 366,000 horse-power.

The J. G. White Management Corporation announces as directors Cecil Barret, of Spencer Trask & Company; F. Q. Brown, of Redmond & Company; P. M. Chandler, of Chandler Brothers & Company, Philadelphia; Arthur Coppell, of Maitland, Coppell & Company; Gano Dunn, president The J. G. White Engineering Corporation; George E. Hardy, of Hodenpyl, Hardy & Company; R. G. Hutchins, Jr., vice-president National Bank of Commerce; R. L. Montgomery, of Montgomery, Clothier & Tyler, Philadelphia; John T. Pratt, of Campbell, Harding & Pratt; Frederick Strauss, of J. & W. Seligman & Company; H. R. Tobey, of N. W. Halsey & Company, and J. G. White, president J. G. White & Company, Inc. And the officers are: J. H. Pardee, president; F. H. Reed and S. L. Selden, vice-presidents, and T. W. Moffat, secretary and treasurer.

The business of the Management Company was established some years ago as a department to supervise the operation of properties in which J. G. White & Company, Inc., was interested. This department, which has now been formed into a separate company, was, on December 31, 1912, acting as Operating or Consulting Operating Manager of public utility and railroad properties in the United States, Nicaragua and the Philippine Islands, including The Manila Electric Railroad & Lighting Corporation and subsidiaries; The Helena (Montana) Light & Railway Company, the Eastern Pennsylvania Railways Company, of Pottsville, Pa., and subsidiaries; the United Light & Railways Company and subsidiaries; the Associated Gas & Electric Company and subsidiaries; the Augusta-Aiken (Georgia) Railway and Electric Corporation and subsidiaries; Pacific Railroad of Nicaragua; Kentucky Public Service Company and subsidiaries; and other properties.

The parent organization, J. G. White & Company, Inc., controls the new companies and will continue as an active financing and owning company.

THE PORT OF PARA, BRAZIL.

The port of Para, Brazil, is described in the October, 1912, "Bulletin" of the Pan-American Union. Para is on the Para River, which belongs to the Amazon system, though not on the main outlet to the largest river bearing that name. It was established as a town as far back as 1700, and has taken its place as the largest rubber shipping port of the district. In 1910 the vessels entering the port of Para numbered 1,969 steamers and 1,668 sailing vessels with a total tonnage of nearly 1,500,000 tons. The opening of the Madeira-Mamoré Railway promises to add considerably to the use of the port. In November, 1907, work was begun on a system of docks with accessory appliances, which provide permanent facilities for the present traffic of the city of Para, as well as for the traffic present and to come from that immense area known as the Amazon Valley, and although addition must later on be made to the docks as they exist now, yet the unit of improvement has been established and further expense should be nothing more than a duplication of that unit. The work is being carried on under an American corporation holding its concessions from the federal government of Brazil. To it is given a monopoly of the port services, construction, and operation of quays, warehouses, and other works at Para within a zone of 18 miles toward the ocean and 12 miles in the other direction, for a period of 65 years, and this period is to extend to 90 years after the completion of the second section of the work. The main channel to the port has a depth of 30 ft., and a total width of about 400 ft. between channel-line buoys. This leads up to the dock, which consists of about one mile of quay wall for ocean-going steamers where there is a depth of 30 ft. at low water of ordinary spring tides. In addition, there is 722 ft. of quay wall for river steamers with a depth of water of 12 and 1,500 ft. of quay wall for still smaller river steamers with a depth of water of 9 ft. 6 in. The quay walls are built of large concrete blocks. Back of the quay is a well-paved platform or roadway on which are warehouses and freight handling machinery. Beyond the warehouses on the city side of the port works proper is a newly finished road about a mile long and 60 ft. broad, making both a boulevard and, with the trees which are being planted, a future park. In addition to the port works proper, the company is building a ship repairing depot with floating drydocks and necessary shops.

COAST TO COAST.

Niagara Falls, Ont.—A by-law to raise $3,000 for increased fire-fighting apparatus carried at the recent election. The by-law to bonus the Vermont Marble Company to the extent of $5,000 was defeated. The money is now being raised by private subscription.

Province of Alberta.—Mr. Charles Mohr, a civil engineer of Seattle, Wash., after an extended trip through northern Alberta, is endeavoring to interest Alberta municipal authorities into the possibilities of the asphalt deposits of this territory. In his estimation the civic authorities should take immediate steps to secure the mineral rights on these resources and then work them jointly.

Transcona, Man.—The second unit in connection with the large Grand Trunk Pacific shops and yards at Transcona, near Winnipeg, has recently been completed. The cost of the first and second units is $500,000, and they include car works foundries, locomotive roundhouses, and 110 miles of trackage in the yards. The shops are among the best on the continent, and all the G.T.P. freight from Western Canada will be handled at the yards there.

Vancouver, B.C.—The Minister of Public Works has received the report of Edward White, the British landscape artist engaged to suggest the location of new departmental buildings on Wellington Street in this city. The report is understood to be the direct opposite of what was proposed by Frederick Todd, of Montreal. The latter favored seven or eight buildings. Mr. White would group the structures and have them fewer in number. The government will decide which plan is preferable and then will likely ask for competition designs.

Prince Albert, Sask.—A report with reference to the civic administration and city development of Prince Albert is being made by Messrs. E. A. James and T. Aird Murray, of Toronto. The report will be made at the first meeting of the city council this year, will deal with the duties of the works commissioner and city engineer, and will incorporate certain suggestions regarding streets, park system, types of suitable pavements, railroad crossings, sewage and water supply, etc.

Ottawa, Ont.—The Ottawa city council have decided to engage two British experts, Sir Alexander Binnie, of London, Eng., water engineer, and Dr. Houston, scientific adviser to the Metropolitan Water Board of London, Eng., to report upon the best supply of pure water for this city. The arrangements for the engaging of the experts were made through Lord Strathcona, high commissioner for Canada, at the request of Premier Borden and Mayor Ellis. Sir Alexander Binnie and Dr. Houston were recommended by Rt. Hon. John Burns, president of the local government board in the Asquith ministry.

Toronto, Ont.—Works Commissioner Harris, in a report to the city council, states that the slow sand filtration plant finished last year for the city supply of water, leaks from five to six million gallons a day. The leakage into the clear water reservoir is nearly 3,000,000 gallons per 24 hours. A special meeting of the Board of Control will discuss the question of obtaining an independent expert's report on the whole question. The results of the test by Commissioner Harris do not coincide with the evidence as given before Judge Winchester at the recent investigation. It was stated then that the total leakage was not over 500,000 gallons a day.

Montreal, Que.—Plans are being prepared in Montreal for a structure, 56 by 75 feet, ten stories in height, to be erected next spring for the Bank of British North America at Edmonton, Alta. The cost of the building, which will occupy a double corner at Jasper Avenue and First Street, is placed at $1,000,000. It is given out that separate tenders will be called in Montreal and Edmonton within six weeks. The building will be steel and brick with ornamental stone facings and is to be fireproof throughout. The entire ground floor will be used by the bank, a portion of it being reserved as residence quarters for members of the bank staff. The rest of the building will be used as offices.

Saskatoon, Sask.—Following the announcement of the the selection of a site for the hospital buildings in connection with the University of Saskatchewan several of the daily papers have given publicity to a report which stated that the site was too low to provide suitable drainage into the present sewerage system without the expenditure of much money. It is learned that provision has been made, however, to have the design of the new traffic bridge, that is to be erected by the provincial government, altered in such a manner that the drainage from the hospital site may be carried over and connected with the intercepting sewer at 25th Street. The civic power cables will also be strung beneath this bridge.

Province of Ontario.—The Hydro-Electric Power Commission of Ontario, Continental Life Building, Toronto, propose some time before the end of January, to call for tenders for the various materials necessary in connection with the construction of approximately 125 miles of double circuit transmission line at 110,000 volts and the necessary equipment for sub-stations for the transforming of 20,000 h.p. from the line to 13,200 volts. Various types of apparatus will be considered; for instance, the different materials for conductors and different types of steel construction for supports. As mentioned above, specifications will be issued about January 15th, and the tenders will be called for in March.

Montreal, P.Q.—The city garbengers will take no more waste picture films to the incinerator in the west end of Montreal. A few days ago an explosion followed the throwing into the large oven of a quantity of the celluloid subsubstance which contains guncotton in its ingredients. The picture films which were sent to be destroyed by one of the picture show establishments of Montreal, were regarded as ordinary garbage. This has been done before but the films were in smaller quantities and nothing was thought of the little puff and the report which followed. But this time a genuine explosion occurred, which set fire to the building. The electric light connections were also burned out. The fire was quickly under control, and Superintendent Chenevert informed the board that the total loss was only about $15.

Sandwich, Ont.—A new steel plant costing over $20,000,000 which will turn out practically all classes of steel is to be built shortly at Sandwich Ont., by the United States Steel Corporation on a property of 1,500 acres with a water frontage of one and a half miles opposite Detroit which it has owned for several years. It is understood that the plant will be built and operated by the Steel Corporation. The present intention is to build a wire mill, rail mill, bar mill and possibly several others. To operate the plant a new subsidiary of the United Steel Corporation will be organized in the Dominion. The corporation's business with Canada in the past has ranged from 350,000 to 400,000 tons annually, representing from $12,000,000 to $15,000,000. The average duty on its sales has been between $6 and $7 per ton. It is expected that a considerable part of the products of this plant will be marketed throughout the Empire.

Edmonton, Alta.—A ten-story building at a cost of $250,000 is being erected at First and May Streets, to be known at the Royal Alexandra Hotel. The foundation has been completed and six stories will be erected in 1913, four floors being added in 1914. The plans, prepared by Messrs. Van

Siclen and Macomber, of Edmonton, show an exterior in renaissance of the latter French period. The first two stories are to be faced with white sandstone, the upper floors being in terra cotta finished with sandstone. The side walls will be of brick, the mansard roof of slate. The main entrance to the rotunda is to be panelled in Canadian marble, the floor being laid in the same material. An elaborately wrought iron marquee will be erected over the main entrance. The rotunda will be spacious, with Canadian marble columns and Honduras mahogany, the panels being so set in as to provide space for trophies and game heads. The upholstering will be in leather, of a design corresponding with the rest of the scheme. There will be 20 rooms on each floor, all having outside light and ventilation, each room being fitted up with a shower bath and other conveniences, including telephones and the latest built-in features. The structure is fireproof throughout, while the staircases and elevator are so arranged that they can be utilized to the greatest measure to give aid in the event of fire.

WHEELER TURBO-AIR PUMP.

The Wheeler Condenser & Engineering Co., Carteret, N.J., announce that they have acquired the American license to build turbo-air pumps of the A. E. G. Type as manufactured in Europe by the Allgemeine Electricitaets Gesellschaft. This air pump is of the rotary water jet type, for motor or steam turbine drive, air being removed from the condenser by ejector action of a series of small water jets and also by positive entrapment of air between successive small slugs of water. A number of these pumps are now under construction at the works of the Wheeler Condenser & Engineering Company, Carteret, N.J.

CHANGING A C. P. R. BRIDGE.

The Canadian Pacific Railroad bridge across the St. Rose River, Canada, had several 160-ft. spans with pin-connected Phœnix trusses, spaced about 20 ft. apart on centres. They were recently replaced by a double line of 80-ft single-track deck-plate girder spans, supported on the old piers and on new ones built between them. The new super-structure was erected and the old superstructure removed without interfering with traffic and without the use of falsework.

The tops of the old piers were cut down to the required elevation to receive the new girders, and the old trusses were transferred to bearings on timber crib-work built to maintain them at the required elevation. The new girders of the Canadian Pacific Railway Company's standard type, weighing about 49 tons per span, were delivered on pairs of flat cars, run across the old bridge to the required positions, unloaded by derrick cars and suspended by tackles hung from transverse beams supported on the top chords of the trusses. The flat cars were released and removed and the floor system quickly removed, allowing the new girders to be lowered to bearings on the old and new piers.

After all of the new girders for one line of single-track spans had thus been erected, the old spans, weighing about 120 tons each, were supported from them and taken down by the derrick cars, after which the deck spans were shifted transversely to their required positions. The girders for the parallel line of single-track spans were delivered on them and erected in position by the derrick cars.

The plate girder spans were fabricated and erected by the Dominion Bridge Company, Montreal, in accordance with the requirements of the Canadian Pacific Railway Company. Mr. P. B. Motley, engineer of bridges, was in charge of the work.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

At the meeting of Section D, Engineering, on Friday, January 3rd, a programme of thirty papers devoted to highway engineering and related subjects occupied the morning and afternoon sessions. The titles of the papers and authors have been published in a previous issue of this journal. The sessions were presided over by Professor Arthur H. Blanchard as chairman and Professor George W. Bissell as secretary.

On Saturday, January 4th, many of the engineers in attendance visited the plant of the Deckman-Duty Company, at which Dunn wire-cut-lug paving brick are manufactured. The inspection trip of the morning, which was made with automobiles also included the examination of various sections of brick and stone block pavements in Cleveland. The tour of inspection was made through the courtesy of Mr. F. B. Dunn and the officials of the Deckman-Duty Company and the National Paving Brick Manufacturers' Association, who, on the preceding evening, entertained many of the engineers present at a dinner given at the Cleveland Athletic Club.

CANADIAN CLAY PRODUCTS MANUFACTURERS' ASSOCIATION.

The annual convention of the Canadian Clay Products Manufacturers' Association is being held in Toronto this week. The association are still pursuing their efforts to secure the establishment of a course in Ceramics in connection with the Faculty of Applied Science and Engineering of the University of Toronto Mr. C. W. Raymond, of the Raymond Brick Machine Company, Dayton, Ohio, in a letter to the association, agreed to give full equipment necessary for the work of such a department, provided one were established. A joint committee, composed of members of the association, members of the Faculty of Applied Science, and representatives of the Engineering Alumni Association, will approach the Board of Governors of the University at an early date to impress upon them the desirability of the founding of such a department.

PERSONAL.

J. O. MOUSSEAU, the member of the Quebec Provincial Parliament for Soulanges, has been appointed to the new provincial portfolio as Minister of Good Roads.

SIR ALEXANDER BINNIE, consulting engineer for London, England, and Dr. Houston, of the Metropolitan Water Board, of London, have been asked to report on the water supply of Ottawa.

D. F. McLEOD, superintendent of public works at Ithaca, N.Y., has been appointed city engineer of New Glasgow, N.S., to take effect after the expiration on February 28 of his present contract with the city of Ithaca.

FRANK C. ASKWITH is at present acting city engineer of Ottawa. He has been attached to the city engineer's department of Ottawa for the past five years, and before that had several years' experience on railroad construction in the West.

N. J. KERR, until recently city engineer of Ottawa, has accepted a position with the Canadian Pacific Railway. He succeeds Mr. N. J. Carry, who resigned on account of poor health, in charge of Shaughnessy Heights, at North Vancouver.

HAROLD PARKER, M. Am. Soc. C.E., first vice-president, Hassam Paving Company, Worcester, Mass., on

January 10th delivered an illustrated lecture on "Specifications Covering Patented Pavements," before the graduate students in Highway Engineering at Columbia University.

LEE MURRAY has been appointed to the seat on the board of directors of Bruce Peebles & Company, Limited, Edinburgh, Scotland, recently vacated by Mr. Chas H. McKuen. Mr. S. E. Bastow and Mr. J. H. Bunting have been appointed joint managers in the place of Mr. Murray, who has retired from the position of general manager of the company.

COMING MEETINGS.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Meeting of Mining Section will be held on Thursday, Jan. 16th, at 8.15 p.m., at the Society's Headquarters, 413 Dorchester Street West, Montreal. Sec'y, C. H. McLeod.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—Third regular meeting of the Toronto Section will be held at the Engineers' Club, 96 King Street West, at 8 p.m., Friday Evening, January 17th, 1913. "Notes on the construction of Toronto Hydro-Electric System." Mr. J. G. Jackson; "Practicability of the Toronto Street Lighting System," Mr. W. R. Sweeney; papers illustrated with stereopticon views. Secretary, H. T. Case, 611 Continental Life Building, Toronto.

THE CLEVELAND ENGINEERING SOCIETY.—Informal meeting, Chamber of Commerce Building, January 21st, 1913. "The Practical Illumination of Factory Buildings (Illustrated)," by Ward Harrison, Illuminating Engineer, The National Electric Lamp Association. Secretary, David Gaehr.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—Annual Meeting, January 14th, 1912, will be held at The Engineers Club, 32 West Fortieth Street, New York, N.Y. Secretary, Eugene W. Stern, 103 Park Avenue, New York.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual Meeting will be held on Jan. 28th, 29th, and 30th, 1913, at the Society's new headquarters, 176 Mansfield St., Montreal. Secretary, C. H. McLeod.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St., Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright Secretary, Mr. Hugh B. Fergusson 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre: Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

The Canadian Engineer

An Engineering Weekly

WATER-POWER FROM THE MISSISSIPPI.

The Large Hydro-Electric Development in the Centre of the United States.

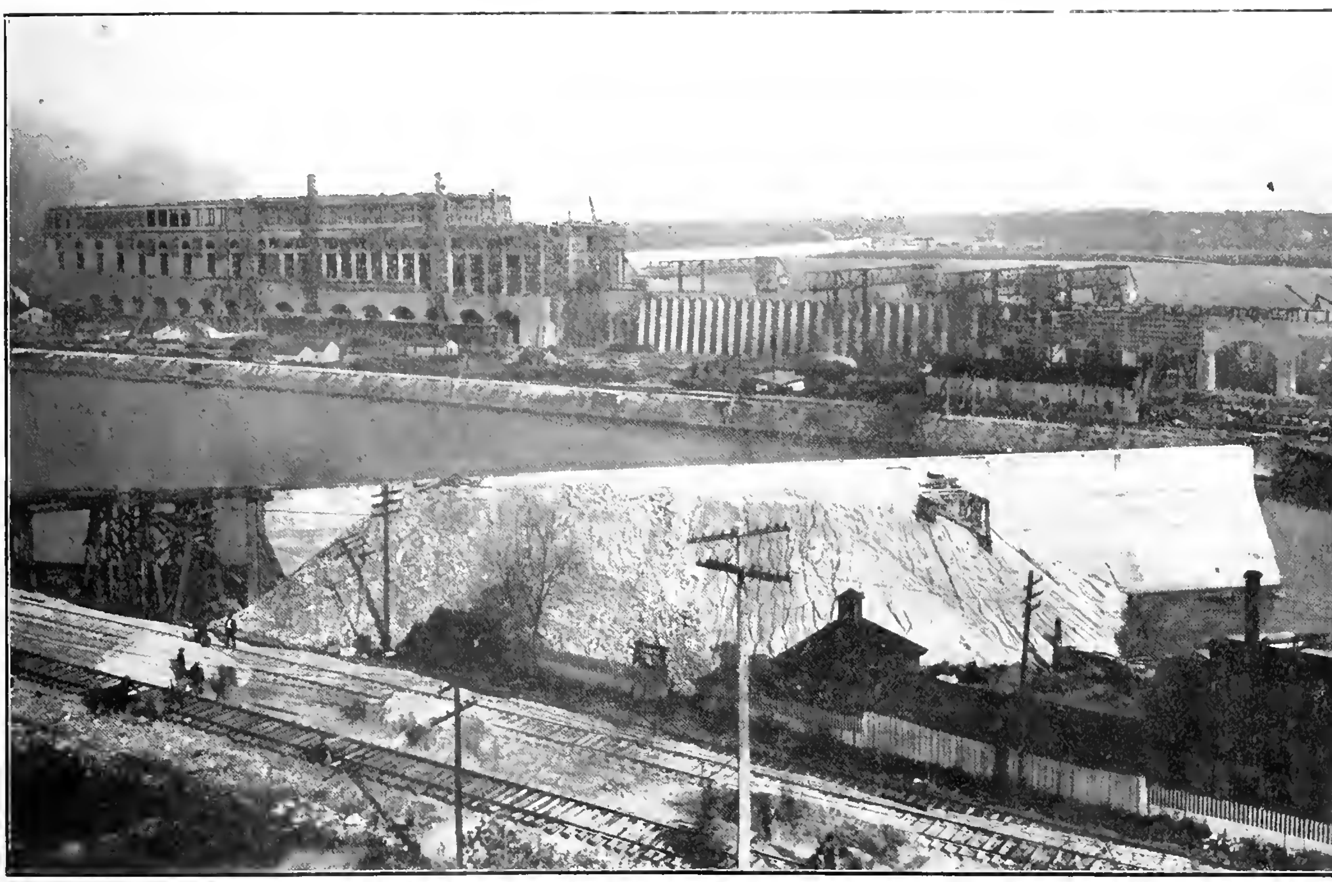
BY G. DONALD DELL

The notable things in the water-power development in the Mississippi River are three: the location; the size of the plant, and the solution of some engineering problems involved.

The location is in the centre of the Mississippi Valley with its large supply of raw materials for factories and its large consumption of manufactured products—and there are no other large water-power sites near this one.

The development at the foot of the Des Moines Rapids in the Mississippi yields over 300,000 horse-power on the turbine shafts. It consists of a dam 4,649 feet long, including the abutments at either end, a power house 1,718 feet long, a large lock with a lift of 40 feet, and a large dry dock, besides appurtenant structures rendered necessary by the conditions found there.

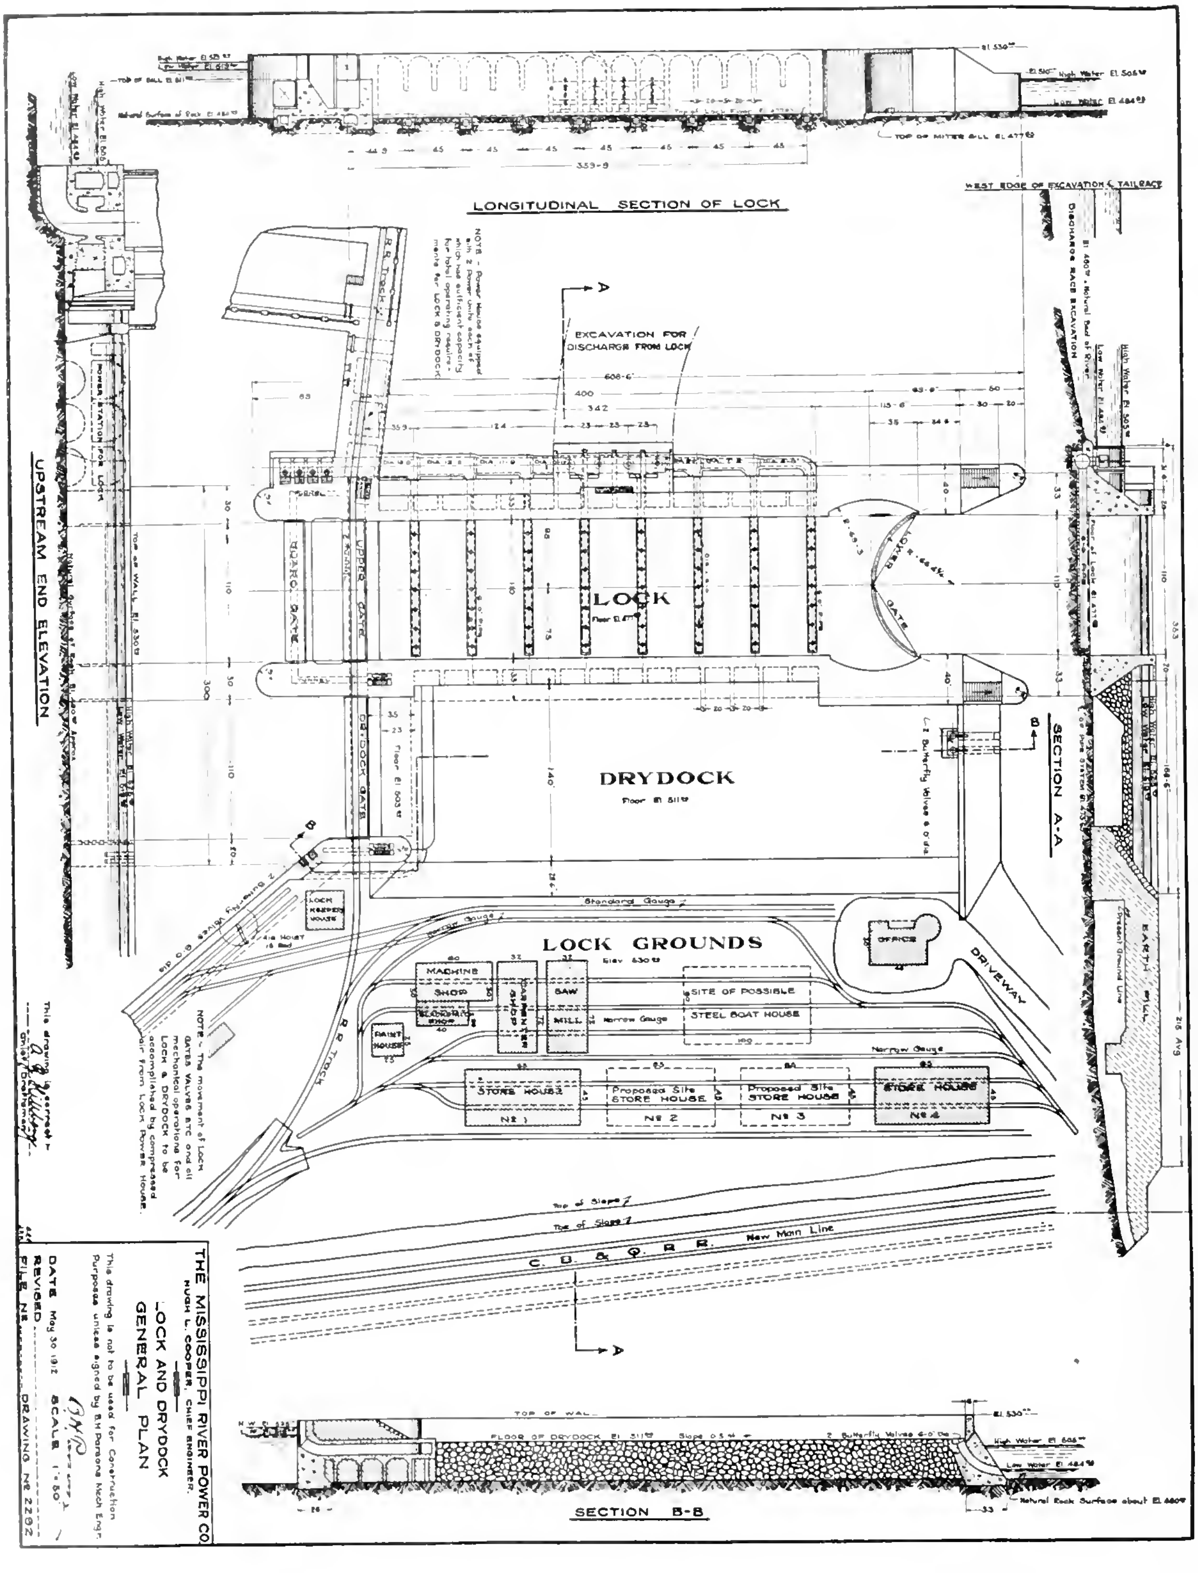
Considerations of river flow prescribed by the United States government regulating navigation, of storage, and of constant head, determined the plan of the dam. It consists of 119 arched spans with 30-foot spaces between 6-foot piers; in each span is a spillway topped by a steel gate. The dam is gravity section, massive concrete with each one of the 119 sections capable of withstanding all stresses upon it without reference to any other part of the structure. At first glance, the dam strongly suggests a bridge, and reduced to its lowest



Part of Forebay Side of Power House, Showing Arch in Front of Each Unit. Behind the Arches are the Pilasters Carrying the Strainers and Separating the Four Intakes to each Turbine.

mechanical terms it is a bridge with spillways between the piers. The spillway portion is 4,278 feet long; the east abutment is 290 feet long, and the west abutment 81 feet long, the latter being integral with the substructure of the power house. The dam structure is 29 feet wide on top and 42 feet wide at the bottom, which is set several feet into the

line of the arch of the span. They are trusses faced with 3/8 inch steel plates and will be operated with a traveling crane running on the top of the dam. The down-stream bearing surface of each slot is faced with an iron plate. When the final installation is completed the surface of the pool will be a little below the tops of the 119 gates, and conditions of



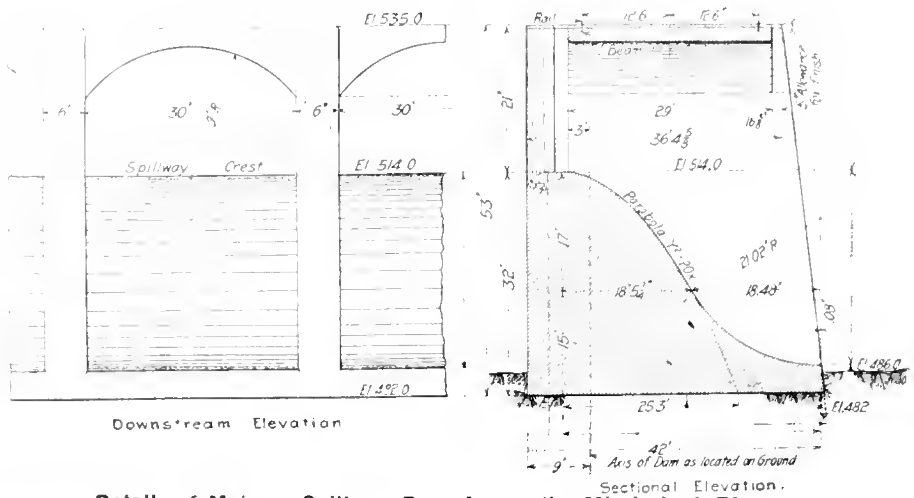
hard limestone bed of the river; the height of the structure is 53 feet and the spillways are 32 feet high.

Each spillway has a vertical up-stream face; the down-stream face of the spillways is an ogee curve. The steel gate on top of each spillway is 32 feet long, working in slots in the piers, and is 11 feet high, reaching to the springing

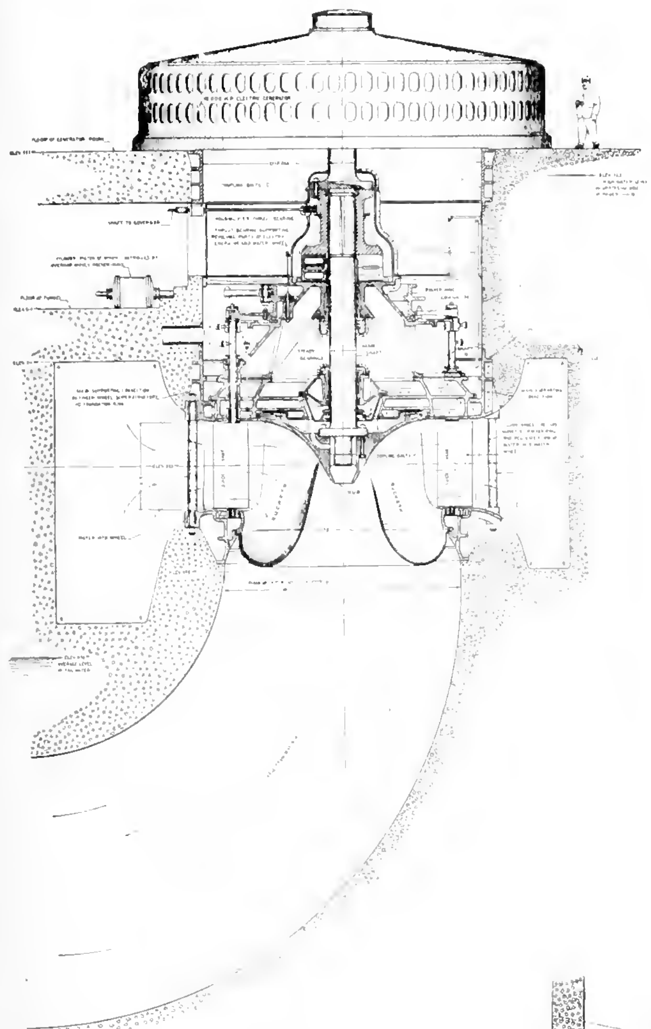
river stages and flow will govern the number of gates open at any one time

In building the dam, a thorough examination was made of its foundation. The river bottom at the side is blue limestone of rather remarkable homogeneity considering the distance involved. The bottom was unwatered by a cofferdam

several hundred feet long built ahead of the progress of the concrete dam itself, section by section as the work advanced. In this cofferdam section was made the excavation to key the dam into the bed-rock. Holes 4 inches in diameter and 30 feet deep were drilled to test for seams and pockets of softer material. Tests of these drill holes were made in three ways: They were dried and carefully inspected later for any moisture; they were put under air pressure after being sealed at the top and the attached gauge examined for any loss of air; the penetration of the drill as an ordinate to time was carefully platted and a regular curve required. The failure of the test hole to withstand these severe tests was cause for special excavation and investigation, although this was practically not necessary in the entire length of the dam.



Details of Main or Spillway Dam Across the Mississippi River.

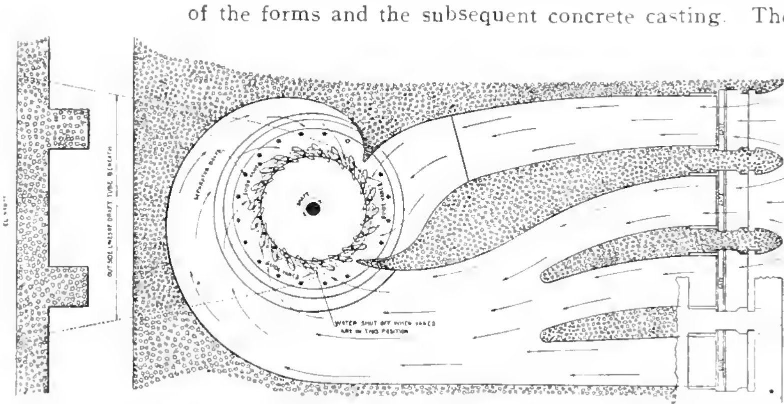


Centre Section of Main Turbine on Transverse Axis of Power House.

Steel forms were used in casting the dam, eight being in use at one time and the rear-most being constantly moved to the front, so that there was no delay on account of the concrete workmen waiting on the form riggers. The parts of each form were made interchangeable with the others. In the bottom member of each pier-form were two holes to fit over two dowel pins projecting from castings set in small concrete piers. There was a main frame for each up-stream and for each down-stream leg of the forms of each pier, and it was in the bottoms of these that

Part of Scroll Case with Turbine Installed, Surrounded by Guide-vanes.

the sockets fit the dowels in the base plates. By careful instrument work, these base plates were accurately located in alignment. After that, the members of the forms and their connecting bolts and stay bolts controlled the alignment of the forms and the subsequent concrete casting. The arch



Plan Showing Method of Conducting Feed Water from Head Bay to Guide-vanes in Front of Runners.

forms were hinged and arranged to be removed after the concrete set without wedges, blocking, or shores. The mixing plant was placed to deliver in the axis of the dam at the eastern end. Three standard gauge railroad tracks on top of the dam carried the concrete from the mixers in one and a half-yard buckets to the forms at the end of the dam in process of construction. There was a cantilever traveler with its cantilever arm 150 feet long extending out over the forms, which picked up the buckets from the cars and dumped them in place. This cantilever traveling crane had a main frame 25 feet by 90 feet, mounted on six heavy steel wheels which ran on a track of 25-foot gauge and 100-pound rails, spanning the three tracks used for hauling the concrete. This cantilever traveler, after its work on this dam was done, was sold to a Canadian company for use on the St. Lawrence.

Junction of the Dam and the Power House, Showing Some Spillways on Top of which go the Steel Gates.

The spillways were built with side dump cars pouring the concrete into conveyers which carried to the forms below, after the main structure of the dam was completed. Temperature variation of volume inducing cracking was provided against by strips of tar paper inserted in every pier and arch.

The power house is set near the Iowa shore almost parallel with the river, with the forebay between it and the Iowa bank, a curve in the river increasing the width of the upper end of the forebay. The substructure, 132 feet 10 inches by 1,718 feet and 70 feet high, was set about 25 feet into the river bottom, the tail race being excavated to the same depth on the eastern side of the power house. It is monolithic concrete in continuation of the dam at one end and the lock and other adjuncts at the other end. It was cast in wooden forms, an area of about thirty-five acres being unwatered in the river for the construction plant there. It contains thirty power units and four exciter-auxiliary units. Gantry cranes were used as concrete conveyers from the trains to the forms. Each turbine is placed in a scroll case 22 feet high and 39 feet in diameter, entered through four intakes so curved and choked as to deliver the water to the turbine runner with equal velocities at every point on the circumference of the wheel. The draft tube of each unit is circular, 18 feet in diameter at the top, and curves down into the tail-race, the lower end being an opening in the superstructure, two semicircles with tangent top and bottom, 22 feet 8 inches in vertical diameter and 40 feet 2 inches in horizontal width. The bottom of the draft tube is at the bottom of the tail race about 25 feet below the river bed. The water velocity at the upper end of the draft tube will be 14 feet per second, and at the exit 4 feet per second.

The turbine here presented the problem of a head of 32 feet with large volume of water and low rotation. As finally worked out, the answer is a turbine of original design, Francis type, of 57.7 r.p.m., efficiency of 86 per cent. by Holyoke test, and a little over 10,000 h.p. on the shaft. The runner has twenty buckets and weighs about 130,000 pounds, is 16 feet 6 inches in diameter and 11 feet 3 inches high. The shaft, with the turbine below and the revolving field of the generator above, is 25 inches in diameter. The weight is supported on one thrust bearing set high in the turbine pit, out of the water, and easily accessible, the top of a cone resting on the foundation ring of the pit liner. The latter is a steel cylinder imbedded in the concrete with rings at top and bottom weighing 100,000 pounds each. The weight on the thrust bearing is 550,000 pounds, and the lubrication is by forced oil with immersed roller bearing in reserve. It is believed that this installation has high dependability as well as satisfactory efficiency. The guide vanes of the regulator are connected to the compression cylinder by levers, rocker rings and cranks. Strainers are placed on buttresses projecting between intakes in front of which an arch for each unit marks the forebay side of the power house substructure.

The architecture of the superstructure is adapted to the electric machinery content, and the walls are of reinforced concrete and the roof trussed. The superstructure from generator floor to roof pinnacle is 107 feet 6 inches, making the total height of the power house 177 feet 6 inches from bottom of draft tubes to pinnacle.

The Lower Side of Part of the Power House, Showing Parts of Lower Ends of Draft Tubes with Exits into the Tail Race Excavated into the Bottom of the Mississippi.

The generators are rated at 9,000 k.v.a., 11,000 volts, three-phase, 25-cycle, with a full load efficiency of 96.3 per cent. and a regulation of 13 per cent. at unity power factor. Each armature is 30 feet 9 inches in diameter, and each gen-

erator weighs 614,000 pounds. Alternators, driven by turbines, supply current of 25 cycles at 4000 volts to three-phase busses running the length of the power house generator room, and from these busses is tapped off a 100 kw. generator set for each generator to excite the latter at 250 volts. The

The Keokuk Lock in the Mississippi During Erection of First Leaf of Lower Gates.

wiring of the electrical installation is worked out with some interesting novelties.

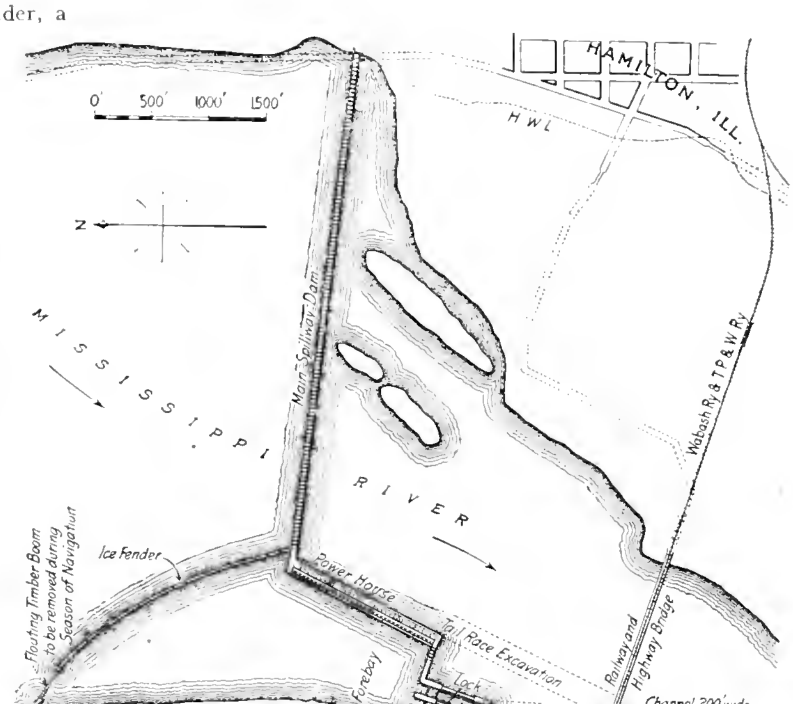
Swinging in a long curve from the western end of the dam across the entrance to the forebay is the ice fender, a concrete bridge with 10-foot piers and 60-foot spans, 8 feet wide at top and 16 feet wide at bottom, with its top 5 feet above high-water and the top of the span openings 4 feet below low-water. At the shore end is a floating boom of timber to permit steamboats to pass.

The shore side of the forebay is a sea-wall 1,100 feet long and 45 feet to 53 feet high, which protects the railway tracks elevated above the new water level above the dam. Fourteen miles of railroad had to be elevated and relocated along the pool.

The lock is at the lower end of the forebay, beside the dry dock, and is connected to the lower end of the power house substructure by a wall in which is placed the small turbines generating power to operate lock and dry dock through compressed air engines. The basin of the lock is 110 feet by 400 feet, and the lift is 40 feet with 8 feet over the sill of the upper gate. The conduit system comprises a main stem 13 feet in diameter under the east wall, with eight cross conduits 6 feet in diameter under the lock floor. In each cross-conduit are seven apertures, making a total of fifty-six openings for filling and emptying the lock chamber. Cylinder valves control the culvert system.

The lower gates are curved to R. 66 feet 4¾ inches inside and of 69 feet 3 inches outside. The versine is 10 feet 8½ inches. Their height is about 50 feet. Buoyancy chambers in the bottom are 12 feet by 31 feet 8 inches in dimensions. Each leaf has thirteen horizontal arched ribs 4 feet apart, connected by heavy girders and nine lines of intermediate framing. The railroad bridge steel, of which it is built, is tested to 65,000 to 70,000 per square inch. The pintles are of nickel-steel with bushings of bronze, and are hemispheres 18 inches in diameter. The mechanism by which these gates will be moved is the same as that at the Gatun locks on the isthmus of Panama, and it will be operated by a 40 h.p. compressed air engine.

The lock is 8 feet over the sill, in harmony with the 6-foot depth of channel being worked out by the government engineers between St. Paul and St. Louis, by order of Congress, with a factor-future of one-third added here. The upper gate of 110-foot span presented a problem which was solved with a gate of unique design. The lock gate and guard are raised to closed position and latched there by a buoyancy chamber, into which compressed air is pumped to replace water. To open the gate, water is allowed to enter the buoyancy chamber. The gate sinks beside the sill and the boat passes over it. Valves control the water and air inlets to the buoyancy chamber, and are themselves operated by compressed air. A rod running the length of the gate has a pinion on each end engaging a vertical rack, this device preventing jamming. Simplicity characterizes the design, and care was taken to make these upper gates "fool-proof," that is, dependable when operated by ordinary laborers. On top of the lock gate will be a standard railroad track, affording entrance to the power house from the railroad systems of the country, and the heaviest loaded freight cars may pass over the gate into the power house to be unloaded there by traveling cranes of 150-ton capacity installed there. Besides the lock gate and the guard gate, there is another gate to the adjoining dry dock chamber, and all three are built interchangeable. Should any gate need repairs, it will be floated, buoyant, into the dry dock, and if necessary, the guard gate may be temporarily used as either the lock gate or the dry dock basin gate. Each gate is easily and quickly removed by disconnecting it at both ends and floating it in the axis of the lock outside of its normal position, where the walls are re-



General Plan of the Dam and Power Plant of the Mississippi River Power Company, at Keokuk, Iowa.

cessed in a curve on each side, permitting the gate to be turned on its own centre and towed away. The dry dock basin is 140 feet wide and 463 feet long on the bottom, and

has a culvert system for filling and emptying it by gravity. It has sloping sides, and the dimensions at the top are 168 feet 6 inches by 468 feet over all. The grounds for machine shops, store house and other government buildings are extensive. This work, which is just beginning with the advent of 1913, requires a fill of 200,000 cubic yards.

The chief engineer of the work, all of which is done by administration, is Hugh L. Cooper, M. Am. Soc. C.E., who organized the Mississippi River Power Company, the proprietor of the water-power development there in which considerable British capital is invested. Mr. Cooper was attracted to the possibilities of the Mississippi development after finishing his labors on the plant of the Electrical Development Company at Niagara Falls, Ontario. He has a large and carefully planned organization on this Mississippi River work, which has progressed with remarkable speed and economy.

A NEW CANADIAN OIL-ENGINED SHIP.

An oil-engined vessel, the "Fordonian," has just been finished and has received her initial trials. The ship was built by the Clyde Shipbuilding and Engineering Company, Limited, of Port Glasgow, Scotland, and is the first vessel built on the Clyde propelled by two-stroke cycle Diesel oil-engines.

The leading dimensions of the ship are 250 ft. long, 42 ft. 6 in. beam, 16 ft. 10 in. moulded depth to the main deck, and 26 ft. 6 in. to the awning deck. The "Fordonian" has a 2-ft. frame pitch, and a dead-weight cargo-carrying capacity of 3,300 tons on 16 ft. 6 in. draught. The draught on service is restricted to 14 ft., and the dead-weight capacity is thus reduced to 2,200 tons. She is built to Lloyd's highest class for the Canadian Interlake Line, Limited, of Toronto, for grain-carrying on the Great Lakes of Canada. The vessel conforms to the standards of Canadian Lake practice in that she has a steering-pole out forward to make quite handy the control from the forward bridge, a large number of hatches, and inward opening cargo-doors on the port and starboard sides to facilitate the rapid removal of cargo. The cofferdam at the forward end of the fore hold is unusual in such vessels, and is intended to preserve the cargo from damage should the ship spring a leak as a result of coming in contact with any one of the many locks through which she passes in her regular trading. There are two independent controls from the bridge to the engine-room telegraph, and the steam steering-engine is operated by rods from the bridge.

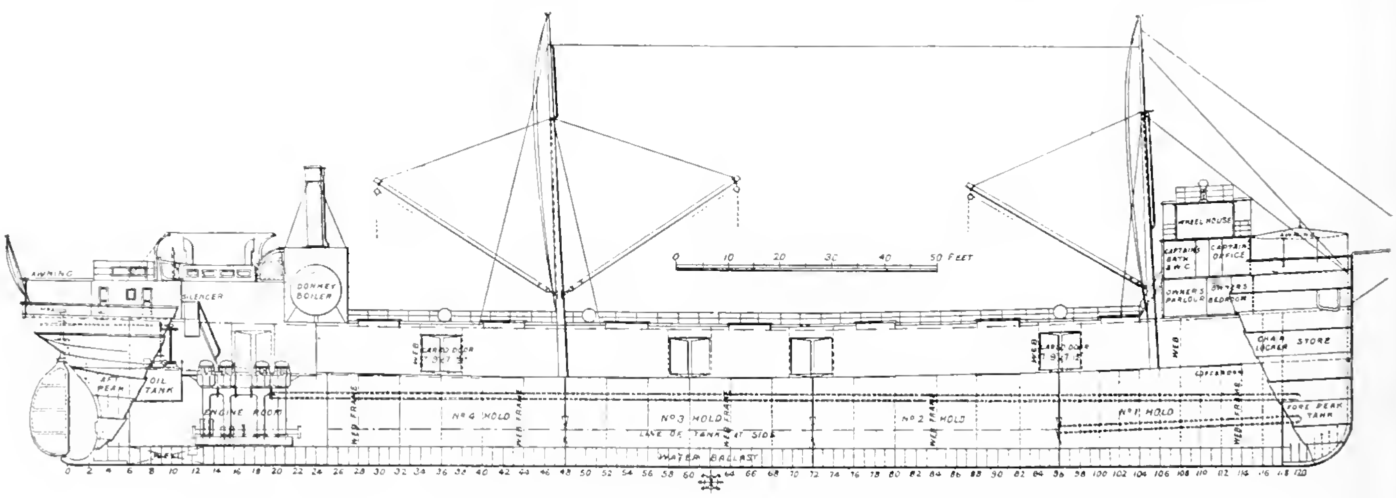
As with sister-ships, there are two masts with derricks on each, and the chart-house and navigating bridge are situated right forward. The rudder is balanced and is of large area. In the trials the vessel turned almost in her own length, and when the helm was put hard over she almost came to a dead stop.

The propeller is 11 ft. 9 in. in diameter by 9 ft. pitch.

The main propelling engine is a four-cylinder two-stroke cycle single-acting Carels type of Diesel oil-engine. The cylinder dimensions are 460 mm. (18.1 in.) diameter by 820 mm. (32.25 in.) stroke, and the engine runs normally at about 100 revolutions per minute. The bed-plate is of cast iron and is of the usual marine design, having a flat bottom and being supported in the centre as well as at the sides. This design contrasts with that evolved by many Continental makers, who prefer the bed-plate supported at the sides only, with the cross-members of deep box section carrying the main bearings, which have forced lubrication. The columns of the engine are of the usual box section, bolted rigidly together at the top, and are very thick, to withstand the tension stresses consequent upon the high pressures of the Diesel cycle. These tend to give great rigidity; the engine ran entirely free from vibration. With this design of support the bed-plate must be strong to take the bending stresses between the column feet and the main bearings.

The arrangement of the engine into two units of two cylinders each permits of a two-piece crank-shaft in interchangeable halves, of the vertical spiral drive for the valve gear being taken from the centre of the engine, and also of the scavenging-pumps being driven from the two centre crossheads by links, as with the air-pump of steam-engines. The dimensions of the double-acting scavenging air-pumps are 27¾ in. in diameter with a 23½-in. stroke, and give thus a ratio of free air compressed for scavenging to combustion air taken into the main cylinders of 1.65, which is higher than the usual practice. The pressure of the scavenging air is 3 lb. per sq. in.

The system of lubrication is interesting. For the main bearings solidified oil is used, for the crank-pin bearings the ordinary drip-feed suffices, and the bearing pressures for the main and crank-pin bearings are respectively about 300 lb. and 650 lb. per sq. in. For the lubrication of the crosshead bearing, a small lubricating-oil forcing-pump is attached to each crosshead, and worked by the swing of each connecting-rod, as shown. This system of lubrication permits of an open crank-case, and the bottom end bearings can always be easily felt by the engineer on watch. There are two guides tor each, such being Messrs. Carels' practice for oil-engines.



The Canadian Inter-Lake Ship "Fordonian."

Built by the Clyde Shipbuilding and Engineering Company, Limited, Port Glasgow.

The piston is lubricated by four Mollerup lubricators, which force the oil between the piston and the cylinder; there are four inlets to the cylinder, and they are arranged to enter on the fore-and-aft and athwartship centre lines.

The control of the engine is by means of one wheel and two levers on the starting-platform; one lever controls the compressed-air engine, which gives the cam-shaft its angular displacement by raising or lowering the vertical driving-shaft, and also gives the manœuvring-shaft its fore-and-aft movement. The other lever controls the fuel. The wheel operated by hand, gives the manœuvring-shaft its rotary motion. The cams upon the manœuvring-shaft act upon the suction-valves of the fuel-oil pump. Hand control is also provided by the handle on the column, which actuates a shaft running fore and aft on the engine, and so sets all the fuel-pump suction-valves. Although compressed air is used for actuating the vertical shaft, causing the angular rotation of the cam-shaft and the rotation and displacement of the manœuvring-shaft, hand-gear in emergency may be used.

Air storage for starting purposes is provided by four welded steel bottles, of 23⅝ in. diameter by 8 ft. long, and that for fuel injection by one bottle, 1 ft. in diameter by 3 ft. long. The pressure of the fuel injection air and the starting air is 850 lb. per sq. in., and for slow-running engines, such as this, this pressure is quite usual practice. The time taken by the auxiliary compressor to fill up the air storage provided is about one hour. The remainder of the auxiliaries are normal steam practice, and call for no special mention.

The weight of the main engine alone is about 100 tons, and if the auxiliaries are included, all ready for work, 150 tons is the weight of machinery abroad.

There is fuel storage in two oil-tanks placed on both sides of the oil-fired donkey boiler, and two ready-use tanks are placed aft of the engine-room, and are provided with steam heating coils, whilst the oil is filtered, on its way to the fuel-pumps of the main engines, through 15-gallon filters in the engine-room. In all 105 tons of oil fuel is carried, whereas with the sister steamships 250 tons of coal is required. The consumption per day for all purposes is 5 tons of oil fuel, against 14 tons of coal.

The fuel consumption of this engine is 0.47 lb. per brake horse-power per hour, and this is good practice for two-stroke cycle engines with the scavenging-pump and air-compressor driven off the main engine. The pressure of compression is 490 lb. per sq. in. The indicated horse-power at 102 revolutions per minute and 90 lb. per sq. in. is 970; 10 knots were achieved with the engines doing 128 revolutions per minute. The maximum revolutions were 140, the normal about 102, and the minimum 46. The results will undoubtedly be improved upon when the engines are finally tuned up, as prior to the trial trip they had only been run in dock trials for twelve hours in all. This is exactly the same treatment as is given to steam-engines.

The crank-shaft is in two interchangeable pieces, and there are two scavenging-pumps of large capacity. The auxiliary air-compressor is of half the capacity of the main compressor, and since the vertical shaft drive for the valve-gear is in the centre of the engine, should the compressor give out, one scavenging-pump fail, or even the crank-shaft break, the main engine will still develop more than half its normal power. This type of engine seems very suited to the propulsion of cargo boats, and the saving in space consequent upon the adoption of the Diesel engine for this ship is five frame spaces, aggregating 10 ft., some 33 per cent. of the machinery space.

A NATIONAL BOARD OF ENGINEERING CONTROL.

By Evolu.

[Some months ago Mr. T. Chase Casgrain, chairman of the International Joint Commission, offered two prizes for the best essays on the Formation of a National Engineering Service. The competition was held under the auspices of the Royal Military College Club and the Canadian Society of Civil Engineers. Through the kindness of Mr. Casgrain, we are enabled to publish the essays which obtained first and second prizes. The following essay, by Evolu, obtained first prize, and that by Observer the second prize.—Editor.]

Emerging from the Central Station in the city of Ottawa to proceed in the direction of Parliament Buildings it is necessary to cross a wide highway bridge spanning the Rideau Canal. The canal and the site of the bridge are enduring monuments to a corps of men whose work may be encountered in every quarter of the globe. Men whose motto is "Ubique": as Kipling says, "The men who do something all 'round' . . . the Corps of Royal Engineers."

The canal, built almost a century ago for purposes of defence, is still in the year 1912 a commercial asset to Canada.

To build the new highway bridge at Ottawa, known as the Plaza, it was found necessary to pull down the arch of the existing Sapper's Bridge, built under the direction of Colonel By in 1828. Before the old bridge could be torn down much labor and dynamite had to be employed. After the arch had been materially weakened a boulder weighing almost a ton, hoisted and dropped from a height of fifty feet, failed to complete the process of demolition. Only after repeated assaults and hours of battering did fall the works of these pioneer engineers; works built to endure, without thought of profit, works built for the common weal.

Thus it is wherever the works of the earliest engineers are found. The Great Wall of China, the Roman roads of Europe . . . how many engineers remember those schoolboy (sometimes painful) efforts to render a faithful translation of the chapter on bridge building in Cæsar's Gallic wars?

Some of the most enduring of the world's historic records are the works of the engineer, almost invariably of the military engineer. It would almost appear that engineering originated as a branch of the art of war, cultivated and developed as a department of state.

The passing of the feudal system witnessed the limitation of military government. But while war has declined, engineering has advanced into vast new fields: evolved from the art of war to the science of industrial civilization. And though some of the most remarkable modern achievements of the engineer, the appalling "Dreadnought" fighting machines and to some extent the Panama Canal, owe their existence to the new military method of preserving peace, nevertheless the civil engineer has outgrown his military parent. So that in modern states, such as the Dominion of Canada, even the military colleges are concerned in educating civil engineers.

Although an offspring may outgrow a parent it does not follow that the larger body necessarily must be the more efficient. There is much to be learned from the past. It would be well if every civil engineer could make a pilgrimage to Ottawa and read, mark, learn and inwardly digest the moral to be learned from those century-old works of the Royal Engineers and Colonel By.

Under the industrial system the stress of competition must be held responsible for tremendous waste and lack of

combined effort. Work and study have suffered through undue baste. Efficiency has been subordinated to expediency. But the error has been recognized. There would appear to be a growing movement in favor of engineering service organized by the state. Such a service may be found in France known as the Societé de Ponts et Chaussees; in India and Egypt where vast engineering projects are carried out by the Civil Service. In the United States the Army Engineers are responsible for the design and construction of federal works—harbors, waterways and canals; the engineering staff at the Panama Canal has proven such an efficient body it is suggested that the entire organization be retained and employed upon a great national undertaking in the Mississippi Valley.

In Canada the various public service departments have each a staff of engineers, but each departments works entirely independent of the others. Practically no steps are taken towards co-operation or systematic organization of the state engineers. In such a magnificent domain, awaiting development, with great engineering problems to be faced and solved, the day has arrived when some move ought to be made in the direction of the scientific handling of national projects. There is great need for a Supreme Court of Engineering.

Amongst the eight million inhabitants of Canada there is ample material for the formation of such a body. The great works of construction already in existence is good evidence of the nation's ability to accomplish any undertaking. National development could be reduced to an exact science by the organized efforts of experienced, far-seeing men, acting in co-operation, acquiring and recording information systematically.

It would not be proposed to make a revolutionary sweep of the present intricate system of departmental engineering, rather to form a nucleus around which the twentieth century organization could be gradually built up. Studying the history of industrial civilization all roads seem to lead to the principle of combination, evolution from distinct units to corporate organizations. The world's captains of industry appear to have worked out an unassailable method of assuring economic efficiency. Without aiming to effect a corner in technical experts—nationalization of the engineering profession is not yet above the horizon of possibility—it would be possible to draw together and form into, let it be termed, a Board of Engineering Control, a number of engineers with experience and ability sufficient to pronounce with authority upon any engineering project. It would be essential that such a board would be entirely non-political, as the Supreme Court of Justice is intended to be. In the engineering profession there is an abundance of public-spirited men doing faithful service in Canada and actuated entirely by love of their work.

In personnel the suggested National Board of Control could consist of five directors, equivalent to president and vice-presidents of a corporation. In the first formation directors might be appointed by a Royal Commission after due investigation of all conditions relating to the engineering expansion of Canada. The Board should have power to fill all vacancies in future, either by promotion or appointment; also power to select from amongst themselves a permanent chairman of the Board. The appointment of director should be for an unlimited period with retiring pension after a specified period of service.

As with the present system of Auditor General, the Board of Engineering Control should be responsible to parliament alone. The Board should have power to dismiss or appoint any subordinate and have authority to suspend or approve any public engineering contract.

Recall of any director could be enacted only by parliament. Each director upon entering office to be required to tender a formal resignation to the Governor-General in Council: the resignation being signed but undated. Should a reason arise making it necessary to recall any particular director a vote could be taken in the House of Commons. With the approval of the members the resignation of the director could be accepted. The date when resignation should take effect could be specified by parliament and filled in by the Governor-General in Council, thus effecting drastic control of any director by the nation through the national house of representatives.

Following upon the successful establishment of a board of directors the process of gradually building up a staff of expert engineers would commence. It would not be proposed to interfere with the regular working system of government departments, other than to consider and to report upon national projects, until the success of the Board, as an instrument for promoting economic efficiency, had been thoroughly established. But the ultimate aim would be transference of the purely technical work from the various independent units and staffs to the central authority of the National Board of Engineering Control.

Momentous questions are looming up regarding the policy of canal construction in Canada. To deal adequately with the great problem of freight transportation by water it would need a completely organized staff of canal experts. The logical proceeding would be to appoint a Chief Engineer of Canals and Water Service responsible to the Board of Control, with the necessary assistant engineers, draughtsmen and technical clerks. Departmental engineers with the necessary experience could be transferred to form the staff. In the process of time similar staffs could be built up, all directly under the Board of Control, to deal with railways, marine service, harbors, and the rest, until the majority of engineers at present scattered through the various departments would have assembled entirely under the direction of the Board. Where necessary a consulting engineer could remain on the staff of an administrative department. So that should questions arise regarding, for instance, the lease of a water power, it would be the consulting engineer's duty to see that the questions were submitted in their proper form with regard to the technical matter. Just as at present the law clerk or auditor of a department might be required to attend to questions coming under the jurisdiction of the Department of Justice or Auditor General.

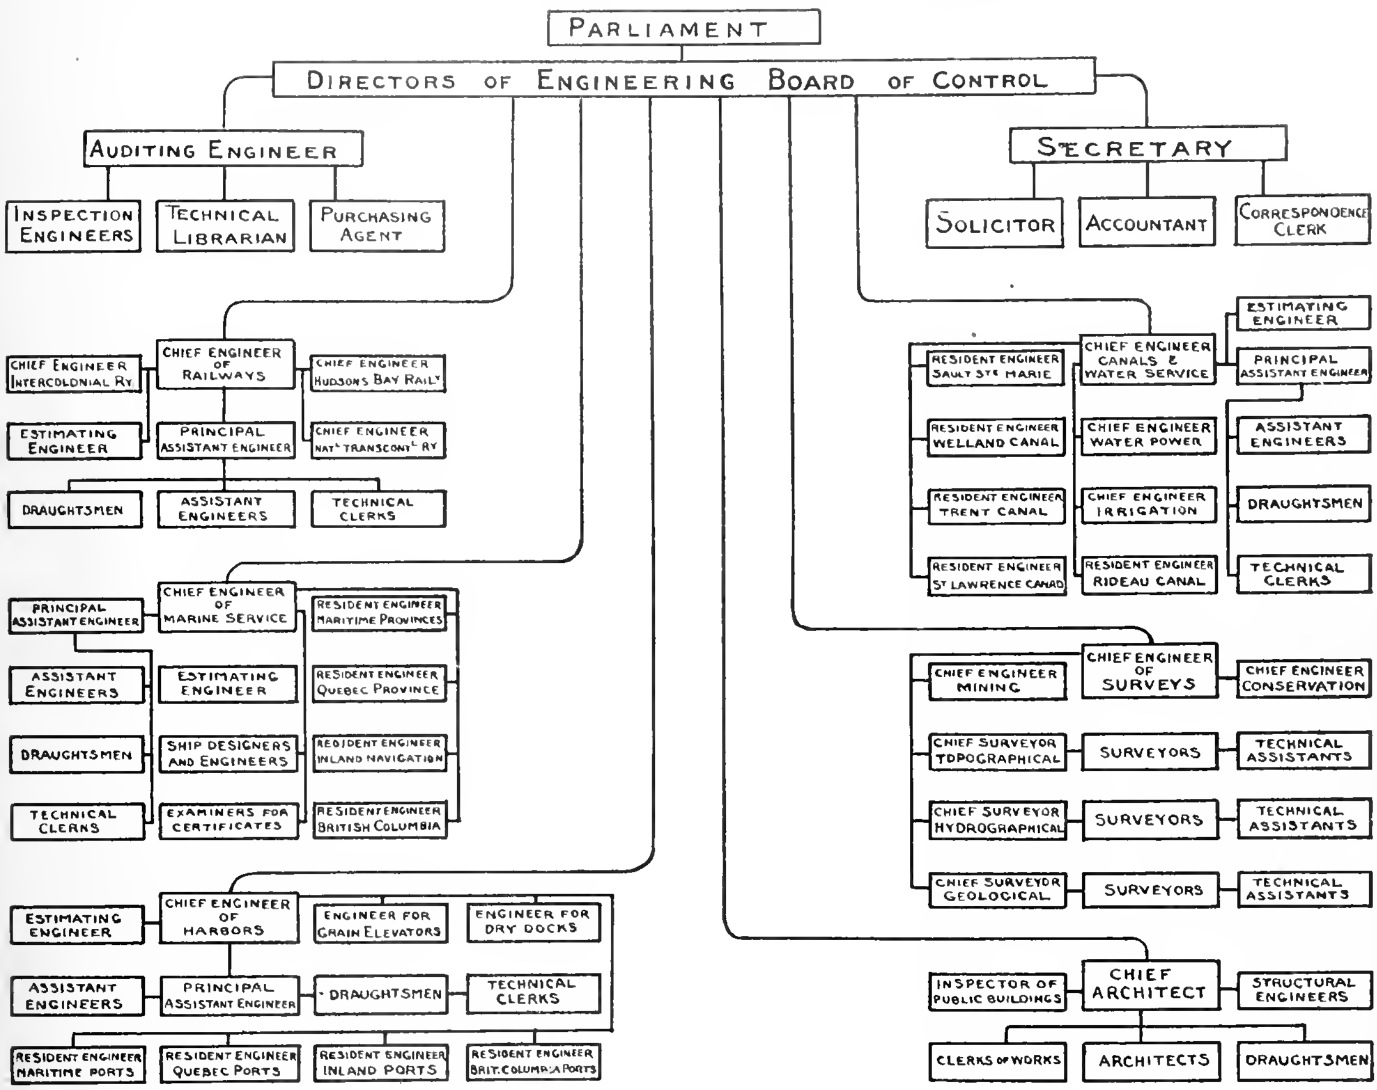
The staff of engineers responsible to the Board of Control would be men widely experienced in particular branches; the Chief Engineer of Railways an expert in railway engineering; Chief Engineer of Marine Service, a qualified engineer in marine work; the Chief Engineer of Canals and Water Service should include on his staff expert hydro-electric engineers and irrigation engineers; Chief of Surveys be responsible for all state surveying and conservation; and Chief Engineer of Harbors include a designer of grain elevators. Each chief engineer would have an estimating assistant who should be especially trained to deal with the economic branch of engineering: economics and finance being the most important features in civil engineering under the present day industrial system. It would be the estimating assistant engineer's duty to have reports prepared and estimates made dealing with the economic aspect of any proposed undertaking. Other assistants, electrical, mechanical, hydraulic, would be included on the staff where necessary. Bridge engineers under the Chief of Railways, ship designers under the Chief of Marine, draughtsmen, inspectors and technical clerks as the work demanded.

An auditing engineer would be responsible to the Board for fair and just expenditure upon such as inspection, sur-

veying, equipment, tools. The inspection and analytical staff, the technical librarian and the purchasing agent for Board of Control supplies also coming under the auditing engineer.

The secretary to the board to deal with correspondence and the direction of affairs through the proper channels, to be responsible through the solicitor for the legal drafting of contracts and specifications, through the accountant for the payment of salaries and accounts, also for advertising of public contracts, and other clerical work.

Thus, to use the diagramatic form of illustration, the proposed Board of Engineering Control might be organized on lines similar to the appendant plan:



The work of the board could be divided under a number of heads, namely, appraising, approving, estimating, surveying, designing, construction, maintenance. Perhaps the most important would be the work of collecting and tabulating information. There has been published at one time and another a tremendous amount of valuable information for the guidance of engineers and those who are concerned in the development of the country. But owing to the lack of cohesion amongst the various departments, and owing to overlapping, lack of responsibility, lack of system, much of the information has been neglected and practically lost. It would be the duty of the Board to place on record all information available regarding the cost of production and distribution of commodities. A technical librarian would be necessary to classify the information, such as reports, blue books, treatises, scientific publications, catalogues, price lists and other literature, and to arrange it in a system easy of access. The librarian could also be responsible for the filing of all maps, charts, plans and drawings, and for the making of blue prints and photographs.

Designing would necessarily occupy an important place in the work of an effective Board of Control. It has been the practice of state departments upon calling for tenders for some particular contract to allow each tendering firm to prepare and submit their own design with the tender. Such a process would not appear to be the most economic nor the most efficient. The system of varying the design according to the schemes of the various tendering firms is the cause of much wasted effort. It being possible to accept only one tender it generally follows that the unsuccessful designs produce nothing. But each design, whether used or wasted, has to be paid for, if not directly then indirectly by the community. Designs have to be prepared by experts. Therefore included in the bid of each tendering firm is a certain percentage to pay for the services of the expert designers. The percentage is usually sufficient to pay out of the profits of one successful contract, the expense (and a little more) of all tenders, whether the design be used or wasted.

For instance, supposing tenders are invited for the construction of an elevator at some point on the grain route, or for a ship, or a bridge, or a post-office—any public utility. Say five companies are invited to tender and submit their own designs. The average price bid may be one million dollars. Possibly five per cent. ($50,000) of the price may be included to cover cost of preparing design. The actual cost

of designing may have amounted to only $5,000: the extra $45,000 goes to pay for unaccepted designs in other unsuccessful tenders.

To the national exchequer a great saving in contracts could be effected by the Board of Control preparing its own designs.

Each contractor bidding upon a different design entirely nullifies the system of awarding contracts to the lowest bidder. The design of the lowest bidder may be, and usually is, far inferior to those of the higher bidders. Thus efficiency may be sacrificed to false economy.

By having one approved design only, each firm would be bidding upon an equal basis. The Board of Control could have sufficient copies of the approved design forwarded to the particular firms invited to tender, and the resultant bids could be compared in regular order ranging from highest to lowest.

Should the Board of Control require several different designs for consideration before inviting tenders, it would be quite possible to have different designs prepared by the staff. Or even to have competitive designs submitted from private, or corporation, consulting engineers, paying for accepted designs before calling for tenders on construction.

It would be the duty of the designing staff to prepare detailed specifications, and with competent inspectors to supervise the work, there would be some assurance that specifications would be followed faithfully, without misleading clauses.

Increased efficiency over the present departmental system of separate engineering staffs could be effected by combining under one management certain work common to several branches. The important and costly work of dredging could be conducted under the supervision of the Chief Engineer of Canals and Water Service instead of three several departments each carrying on dredging contracts. An experienced bridge engineer could be responsible for the accuracy of all important structural steel work. The naval architect under the Chief Engineer of Marine Service could design vessels, canal tugs, dredges, survey ships, lighthouse supply ships, irrespective of the branch under which they might happen to be controlled.

Contracting, or actual construction work, by state employees, is not looked upon with favor at present. There is an erroneous impression in Canada that it is more profitable to let out work to private contractors. But the day may come when the nation shall realize the moral of Sapper's Bridge and the Rideau Canal built by those state servants known as the Royal Engineers. The Board of Engineering Control should be competent to undertake such work when occasion called.

It should be within the power of the Board to compile a list of all corporations and contractors entitled to perform work for the state. Only firms, or individuals, upon the approved list to be afforded the privilege of tendering for state work. The Board to reserve the right to add to, or expunge from, the list any undesirable or defaulting contractor. Such a list is effectively used to maintain a high standard of efficiency in British Admiralty work, where the annual expenditure amounts to £45,000,000 (over two hundred million dollars per annum).

Outside engineering staffs, those of the national railways, canals, lighthouse engineering and the rest, would pass automatically under the control of the Board.

There would be practically no change in the routine work of the various departments outside of the technical staff. But by relieving the deputy ministers of the responsibility of attending to technical work there would be a great relief of pressure upon the several executive heads. A desirable state of affairs which one may be sure would be welcomed by the ministers of the Crown.

Qualification for an appointment under the Board of Control would be based strictly upon experience and ability as an engineer. Any attempt to introduce irrelevant influence, appeals to members of parliament or commissioners, or any other than the mode of application specified by the Board should be deemed sufficient to cancel an application.

With the successful establishment of the Board of Engineering Control responsible to the Federal Parliament it might be possible to expand the principle to the various provinces and towns, provincial and city, or local engineering boards being founded upon similar lines. Provincial Boards to stand in relation to the national board on a basis similar to the standing of the Provincial Courts of Justice and the Supreme Court, making it possible for a city or a provincial board to appeal to the national board where its opinion might be desired.

To sum up: Instead of the present system of disorganized units scattered in various departments the National Board of Engineering Control would draw together to act in co-operation a staff of men with the highest grade of experience in the engineering development of Canada. The board would act as a court of appeal to the many engineering projects vital to the country's well-being. All designs and expenditure for state work, down to the very smallest contract, would be examined and approved before authorizing the execution of the contract. Estimated costs would be prepared, economy, efficiency and accuracy would be ensured by the board before launching any state work.

With such an organization as the suggested Board of Engineering Control, Canada might hope to see greatly increased efficiency in the maintenance and development of national undertakings. And in the consideration of new projects more exact information and foresight. The engineering profession while growing more universal would grow also in stability.

And although the era of war, with its inspiration to great achievements in art and science, may pass, engineering in Canada and in the world would progress from triumph to triumph in the never-ending war between humanity and nature.

THE ORGANIZATION OF A CORPS OF CIVIL ENGINEERS FOR PUBLIC WORKS SERVICES IN THE DOMINION OF CANADA

By Observer.

In considering the suggestion for the organization of personnel for public works services in the Dominion of Canada, a brief description is necessary of departments for the carrying out of public services of an engineering nature in some other parts of the world; only two countries have been selected.

IN THE BRITISH EMPIRE.

(1) India.
(2) Colonial Possessions.
(3) The United Kingdom.

where the long record of successful engineering works carried out by engineers of our own race is one worthy of careful consideration.

IN THE UNITED STATES.

Where, to a certain extent, natural features and climatic conditions have presented engineering problems similar to those of the Dominion which have been handled by engineers with educational qualifications of a similar nature to those acquired at Canadian engineering institutions.

An outlined scheme for the development of a public works service in Canada will then be put forward for consideration.

The British Empire.—In newly acquired territories it has been the usual procedure that, during the process of development, the government has turned to military engineers to carry out the pioneer work of the country. As the public works increase in importance and magnitude and the country settles down, the formation of a civil engineering department has been undertaken, recruited partly from the military engineer corps and partly from civil engineering institutions.

The difficulty in the organization of these departments has been in the adjustment of the conditions of service for the personnel recruited from the two sources, so that they shall work together harmoniously, the strong points of the one class supporting the weak points of the other.

The military engineer brings to the public service a good general education, the power of organization, and a ground work of engineering knowledge on many subjects coupled with the habits of obedience and discipline acquired from his military training.

The civil engineer brings a higher standard of engineering knowledge from a specialized course at an engineering college; he is, as a rule, a specialist in one particular line, in which he excels over his military confrére; but he is not so adaptable as his rival, who usually has a better grounding in general education on which to build technical knowledge during his career. Moreover, the attractions of an independent engineering career in civil life, with its higher rewards for success, draw away the best class of engineers from the public service, which appeals more to the engineering graduate of lower attainments and less ambition, who is drawn by the fixed salary on a graduate scale, and the prospect of a pension in later years.

The selection of candidates for the public service in Great Britain, India and the Colonies, is made under certain conditions by competitive examination tests conducted by a public examining body termed civil service commissioners, who are appointed "at pleasure" by orders-in-council.

The civil service commissioners in the Uniter Kingdom, who examine candidates for entry into the public service in all its many departments under conditions laid down by these departments, consist of two commissioners only, who hold office practically for life, so as to ensure continuity of policy and procedure.

These commissioners select examiners and critics for the preparation and marking of examination papers, exercise a general control over the papers set, and conduct the detailed arrangements for examination, namely, publishing announcements of examinations and syllabi, collecting entries of candidates, supervising written and practical examinations of candidates, checking, collating and recording marks, and preparing and publishing lists of results.

INDIA.

The Railway Department deals directly only with railway systems that are the property of government; the department is sub-divided into two main branches: (1) Construction, and (2) Traffic. **Construction** includes the survey and construction of new lines and the maintenance of existing lines. From this branch are selected the consulting railway engineers to government, whose duties cover the inspection of lines owned or worked by companies.

The Traffic branch handles passenger and freight traffic on open lines; from this branch the managers of both state-owned and company lines are usually selected.

Locomotive and audit branches, with personnel recruited from other sources, are usually separate from the other two.

The Public Works Department is divided into two branches:

(1) Buildings and Roads.
(2) Irrigation.

The Building and Roads Branch deals with the construction and maintenance of all government buildings and main roads, outside military cantonments. The country is divided into areas corresponding to the civil administrative districts, with public works department officials on the staff of the civil administration.

The Irrigation Branch controls the construction of new canals and reservoirs, the maintenance of existing irrigation works, and the distribution of water for agricultural and other purposes. Irrigation is carried out either by diverting the supply from the main rivers by means of canals (Punjab and Ganges Canal System) or by damming large catchment areas to retain the periodical rainfall either by one large tank or a series of smaller ones, (Mysore Tank System). The largest projects undertaken are the Periyar Reservoir, and the Mari Kunaway Reservoir, the latter having a water area of 120 square miles.

The engineers in the higher grades are drawn partly from the Royal Engineers and partly from civil engineer graduates in the United Kingdom.

The Royal Engineers remain on the active list of the corps, receive periodical military promotion, qualify for military pensions, and are liable to recall to military duty when required; they receive pay at civil rates, department promotion and periodical furloughs (on military pay) similar to the civil engineers of the railway and public works departments.

The commissioned ranks of the Royal Engineers are recruited by competitive examination amongst the cadets of the Royal Military Academy, Woolwich, after a two-year course of study; about thirty commissions are offered annually (one commission annually is offered at the Royal Military College, Kingston). After receiving a commission in the Royal Engineers, and before proceeding to India, a two-year course is followed at the School of Military Engineering, Chatham, including occasionally a six months course of instruction on a British railway.

Engineers of the public works department are lent to native states in India for local public works departments; Lieut.-Colonel Joly de Lothbiniere, R.E., a graduate from the Royal Military College, Kingston, has served in the states of Mysore and Kashmir, being at present chief engineer in the latter state.

The civil engineers used to be recruited from the Royal Indian Engineering College at Cooper's Hill, England, after a three years course of study. This college was abandoned some years ago, and now civil engineers are obtained by competitive examination from graduates at engineering colleges in the United Kingdom. The supply, however, hardly meets the demand, and there is a tendency to increase the proportion of Royal Engineer officers in the higher grades.

The various grades in the railway and public works departments with approximate rates of pay for each year's service are as shown below; these rates of pay are not so high as are given in the army administrative departments in India, (i.e., supply and transport, ordnance and accounts); it has also to be remembered that Royal Engineer officers have to keep up military uniforms, equipment and field kit, pay regimental subscriptions, meet extra expenditure involved by active military service, and receive less favorable pay while on furlough than the civilian engineers in the Indian public works department.

Approximate Rates of Pay in Public Works Department, India, by Length of Service.

Years of Service	Military Rank in R.E.	Grade in P.W.D.	Rate of pay per mensem	Equivalent in Dollars per Annum
32	Colonel	Chief Engineer, 3rd grade	2127 Rs.	$8,508

There are two higher grades of chief engineer.

Approximate Rates of Pay in Public Works Department, India, by Length of Service.

Years of Service	Military Rank in R.E.	Grade in P.W.D.	Rate of pay per mensem	Equivalent in Dollars per Annum
31 30	Lieut.-Col.	Superintending Engineer, 1st grade	1915 Rs.	$7,660
29 28	"	Superintending Engineer, 2nd grade	1861 Rs.	$7,244
27	"	Superintending Engineer,	1692 Rs.	$6,768
26	Major	3rd grade	1540 Rs.	$6,160
25 24 23	"	Executive Engineer, 1st grade	1445 Rs.	$5,780
22 21 20	"	Executive Engineer, 2nd grade	1149 Rs.	$4,596
19 18 17 16	Captain	Executive Engineer, 3rd Grade	939 Rs.	$3,756
15 14 13 12	"	Assistant Engineer, 1st grade	780 Rs.	$3,120
11 10 9 8	Lieutenant	Assistant Engineer, 2nd grade	548 Rs.	$2,192
7 6 5 4	"	Assistant Engineer, 3rd grade	496 Rs.	$1,984
3	2nd Lieutenant	"	439 Rs.	$1 756

The following Indian military pensions may be earned by Royal Engineer officers, who have served all their time in India (except three years at the School of Military Engineering and with the Royal Engineer units in England under 15 years' service):

After 20 years' service, 250 pounds per annum.
After 24 years' service, 365 pounds per annum.
After 26 years' service, 432 pounds per annum.
After 28 years' service, 500 pounds per annum.
After 30 years' service, 600 pounds per annum.
After 32 years' service, 700 pounds per annum.

Survey of India.—Besides the railway and public works departments there is another public department in India which is entirely manned by military officers, the survey of India.

This department is divided into three branches: Trigonometrical, Topographical and Revenue.

For those gifted with a talent for higher mathematics, a liking for delicate instruments, and an interest in geodesy and astronomy, the trigonometrical branch affords full scope. The framework of all mapping is based on the work of this branch.

The topographical branch carries out any original topographical work (nearly all the country within the British frontier has now been surveyed) and periodical revisions of existing maps; about six or eight months are spent under canvas every year.

The revenue branch prepares cadastral plans for revenue purposes in settled districts.

Besides these branches some officers are employed on tidal and magnetic surveys, and in the instrument and map producing offices at Calcutta.

The rates of pay are slightly higher than in the public works department; the officers belong to the Royal Engineers, with a few specially selected officers from the Indian army.

Indian Telegraph Department.—This department used to draw on Royal Engineer officers to fill the higher grades, but as a succession of Royal Engineer officers filled the post of director-general for some years, it was decided that the employment of military officers was not in the interests of the civilians in the department.

Except for a few junior Royal Engineer officers under instruction for two years, none have been employed in recent years. This department has recently been amalgamated with the post office department, following the post and telegraph organizations in the United Kingdom. No private telegraph or telephone companies are allowed in India; these services being reserved for government revenue purposes.

The personnel of this department used to be recruited principally from the Royal Indian Engineering College, Cooper's Hill, but in recent years candidates have been selected by open competitive examination held by the Civil Service Commission, followed by a course of instruction at a University in the United Kingdom.

Railway Construction by Military Labor.—It is very customary for sapper and miner companies, under their own officers, to be employed on railway construction work by contract, in unsettled districts, or in districts where civil labor is difficult to obtain.

The Khushalgarh-Kohat-Thol Railway on the northwest frontier, and parts of the Southern Punjab Railway, amongst many others, have been entirely constructed by military labor under military contract.

The sapper and miner companies draw their ordinary regimental pay from army funds; while, instead of engineer pay, a contract is agreed upon between the railway department officials and the commanding officers concerned.

The number of Royal Engineer officers at present employed in the government departments in India is as follows:

Railway Department.

Managers and assistant managers	5
Engineering department (including government consulting engineers)	37
Traffic department	5

Public Works Department.

Road and buildings	23
Irrigation	5
Miscellaneous civil appointments	13

Survey of India.

	40

EGYPT AND THE SOUDAN.

When Egypt was first taken over for administrative purposes after the downfall of Arabi Pasha, in 1882, the country was administered entirely by military officers.

Gradually, as the country settled down, the military administrators and engineers were replaced by civilians, and the military officers concentrated for constructing the military railway, which eventually carried the British flag back to Khartoum.

Since the overflow of the power of the Khalifa the government of the Soudan has been carried out under military administration.

The governors of provinces are infantry officers, seconded from their regiments, while the postal and telegraph department, survey department, public works department, are entirely controlled by engineer officers.

The Soudan Railway, from Port Soudan on the Red sea to Khartoum, with its branches, is also entirely controlled by engineer officers.

The following number of Royal Engineer officers are at present employed:—

Soudan Railway	6
Posts and telegraphs	2
Public works department	3
Survey	1

besides six officers on the railway, telegraph and survey departments in Egypt proper.

COLONIAL POSSESSIONS IN AFRICA.

Besides the military governors and administrators in the various Crown colonies and dependencies in Africa (excluding United South Africa) the surveys of the British African possessions are being carried out by some twelve Royal Engineer officers, besides four employed on railway and road work.

The Baro-Kano Railway in Nigeria and the Uganda Railway have furnished employment for many engineer officers.

THE UNITED KINGDOM.

Telegraphs.—The general post office in Ireland furnishes permanent employment for officers, non commissioned officers and men of "K" Telegraph Company of the Royal Engineers, seven officers and about 150 other ranks. The officers are selected from those who have served in the field telegraph units, while the men are specially recruited from telegraph employees of the general post office. The men undergo a short course of military training and then return to their civil duties under the general post office (on civil rates of pay), but retain liability to recall to the colors when required for active service and periodical training. Practically all the telegraphs in the South of Ireland are worked by "K" Company Royal Engineers.

Special Reserve of Officers for General Service in the Royal Engineers.—In addition to the regular officers of the Royal Engineers, a reserve of junior officers for employment on active service was started in 1900.

Before appointment a candidate must have qualified by examination as an Associate Member of the Institute of Civil Engineers.

After appointment the special reserve officer carries out a short course of military training at the School of Military Engineering, Chatham, and is expected to do a short annual training with a regular engineer unit on field training and manœuvres.

No promotions are made above the rank of captain, nor will any officer be retained in the reserve above the age of 45 years.

There are at present 91 officers on the reserve list, but of these the following are shown as "on leave":

In India	18
In Africa	11
In Canada	4
Elsewhere abroad	6
	39

It will be seen, therefore, that no restriction is placed on young engineers leaving the United Kingdom, but they remain liable to recall to military duty when required.

An annual retaining fee is paid, with military pay and allowances while under instruction or training.

The Ordnance Survey in the United Kingdom is manned principally by engineer officers and men in the Survey Companies of the Royal Engineers. The control is entirely in the hands of engineer officers.

The department originally started under the master general of the ordnance (hence its designation), as the necessity of systematic mapping work was, and always has been, first recognized by the army. After subsequent reorganizations, it has now been placed under the home office, by which part of the pay and allowances of the personnel are provided.

The existing topographical maps on various scales are revised periodically, and cadastral plans prepared as required; the production of maps and distribution on payment to the public are also entrusted to this department, in which twenty Royal Engineer officers are employed.

Other Government Departments provide employment for engineer officers on the retired list as follows:—

Board of Inland Revenue	1
Board of Education	1
Board of Trade, London traffic	2
Government railway inspectors	4
Local Government Board	2
Admiralty (Works Department)	1
Light Railways Commission	1
Prisons Commission	2
Crown agents for colonies	2
Office of Works	3
General post office	2
Total	21

From the above brief description of the duties and emplopment of the commissioned ranks of the Corps of Royal Engineers, it will be seen that their duties are many and varied, and that the government has not hesitated to employ military engineers to a great extent on duties unconnected with the military profession. It is no doubt a system which is full of anomalies and capable of improvement, but it is the the result of many years' slow development, and it is worth taking into consideration when formulating proposals to suit Canadian conditions.

THE UNITED STATES.

The corps of engineers in the United States army was first organized on a small scale under a Federal Act in 1802. Between 1808 and 1863 a separate Bureau of Topography and a corps of topographical engineers was established under the War Department, being finally merged in the latter year into the corps of engineers.

The corps of engineers was first employed on public works service in 1824, when the President was authorized "to procure the necessary surveys, plans and estimates upon the subject of roads and canals." This work was to be carried out "by two or more civil engineers and such officers of the corps of engineers, or who may be detailed to do duty with that corps, as the President might think proper."

From the year 1832 both the corps of engineers and topographical engineers have been constantly employed in public works under the federal government; in fact, until recent years these have been the only government officials who have been available to carry out technical duties of this nature.

Amongst the works carried out may be cited:—

Construction of roads and canals.

Survey of the coast of the United States.

Light-house service.

Bridges.

Harbors.

Reclamation of land.

Railway surveys, including that from the Mississippi to the Pacific Coast in 1853

All public works in the District of Columbia.

And last, but not least, the construction of the Panama Canal.

The successful execution of this latter work being largely due to the co-operation of the military medical department in sanitary work.

As has been the experience in the British Empire during the process of developing the country the civil engineering work has largely been carried out by military engineers. As the country has developed the work has been taken out of the hands of the military engineers, and has been entrusted to civil engineers employed permanently or temporarily by the federal government.

Public works under the control of the various States have, however, been carried out by civil engineers, as no military engineers have been available for States duties.

The same procedure has been adopted in Cuba and the Phillipines on their acquisition by the United States; all administrative legal and technical work of government has has been carried out by soldiers, as has been the case in British possessions.

It has not been custom ary to a ward any higher rates of pay to engineer officers employed on public works than are allotted to officers employed on ordinary military duty. These rates, however, are considerably higher than are paid to officers of the Canadian permanent force or Royal Engineer officers employed on regimental duty.

CANADA.

In Canada the main sources of supply for engineers are:

(a) The Canadian universities, which are in close touch with the principal employers of labor in the country, and which have adopted courses of study particularly suited to local conditions.

(b) The Royal Military College of Canada, where a course of study embracing both civil and military subjects, has been adopted, and whence a large proportion of graduates adopt a civil career, either directly after they leave the college or after a subsequent course at a Canadian university.

(c) The lower grades of the engineering profession in which practical experience is gained by work commencing often at an early age, in the elementary and unskilled stages; finally, after a long apprenticeship, personal ability, skill, and engineering knowledge acquired by years of practical work, have enabled many of the foremost Canadian engineers of the present day to rise to the top of their profession.

The system of selection to fill engineering appointments in private as well as in government service has, however, been somewhat haphazard. Personal influence, as well as political considerations, have often been the determining factors in selecting candidates for appointments. In the absence of any obligatory theoretical engineering qualifications particular attention has usually been paid to practical, as opposed to theoretical, qualifications.

Four years of practical experience in the unskilled branches of the profession are often held of more account than a four-year course of study at a university.

The three government departments in which officials with technical engineering knowledge are required, are:—

Department of Railways and Canals.
Department of Public Works.
Department of the Interior (for topographical surveyors).

Outlined Scheme for Canadian Public Works Service.— It is suggested that a public works service be formed in Canada, consisting of two main divisions.

The first division to consist of higher officials with the grades of:—

Assistant engineer.
Executive engineer.
Superintending engineer.
Chief engineer.

The second division to consist of subordinate officials with the grades of:—

Foremen of works, and other lower grades, with at least six different classes.

Appointments to the second division to be made by selection from those who have served an apprenticeship in practical work. Opportunities would be given to selected men of this division to transfer to the first division, by reserving a proportion of the appointments therein annually for nominations amongst especially qualified foremen of works.

Direct appointments to the first division to be made by open competition, held by a permanent examining board appointed by orders-in-council, among graduates in certain specified branches of engineering at Canadian universities.

Graduates from the Royal Military College, Kingston, would be eligible to compete, but only after they had completed their three-year course at Kingston by a fourth year at a Canadian university. The course of instruction in engineering subjects at the Royal Military College, Kingston, would require revision so as to bring it into line with those arranged for the first three years course of study for an engineering degree at Canadian universities. As many subjects, other than civil engineering, are studied at the Royal Military College, Kingston, the standard required from Royal Military College graduates at the end of their fourth year at a university would necessarily be lower than that required from other graduates.

On appointment to the first division of the public works service candidates would be graded as assistant engineers and encouraged to specialize in one particular branch of engineering.

A further course of instruction at a university in special branches of engineering might be arranged during the winter months for assistant engineers with at least four years practical experience in departmental work.

The rates of pay in the grade would be based on (a) length of service; (b) actual appointment held.

An annual rate of pay on a graduated scale according to length of service, with additional "grade" pay as assistant, executive, etc., engineer, would be the most satisfactory solution. Graduated pensions, after 20 years government service, would induce good men to remain in government service late in life.

Appointments to the various grades would be made by selection according to the importance of the duties to be carried out and to the capability of the engineer. There should be no restriction to a junior engineer holding an important appointment (with "grade" pay accordingly) if he were professionally capable to hold the position. The less gifted members would receive annual increments of pay in the lower grades for the length of service.

In order to bring the engineers of the public works service into closer touch with those employed by private firms, the former should be permitted to accept appointments in private firms, if offered to them; but after the conclusion of a fixed term of years (seven or ten) with a private firm, they should be required to retire from the public works service or to return to government duty. While employed by a private firm a contribution towards pension would be required, so long as the public works department engineer remained eligible for a government pension.

In each government department the senior public works official would be the head of the service in his particular department. All appointments, promotions, and transfers of public works officials would be made by the responsible minister on the recommendation of the head of the public works service in his department, who would always be a permanent government employee, unaffected by a change of government.

A society of the public works service, composed of public works officials in all departments, with an elected president and council, would ensure stability to the service, and would be a connecting link for the furtherance of the interests of the members in general.

The creation of a scientific public works service in Canada, organized on the above lines, would provide a strong body of men, possessed of experience in technical matters, sufficiently permanent in government employ to ensure continuity of policy, and capable of placing at the disposal of Canada's representatives in parliament technical advice on economics, as well as engineering, questions, which would go far towards the expenditure of public funds to the best advantage of the Dominion

CONTENTS OF THIS ISSUE.

A NATIONAL ENGINEERING SERVICE.

Any engineer who has stopped to consider the question of civil engineering as handled with regard to Government service in Canada, must be struck with the general lack of efficiency and the overlapping of departments in the Canadian Government service.

Mr. T. Chase Casgrain, chairman of the International Joint Commission, a few months ago offered two prizes for the best essays on the "Formation of a National Engineering Service." In this issue will be found the two essays which secured first and second prize. These articles will repay careful reading, for they show very clearly some of the difficulties of the present conditions at Ottawa.

As conditions now exist, a number of departments of the Government service carry on work in which the engineering profession are vitally interested, and for which members of that profession are responsible, both in design and execution. A lack of efficiency is conspicuous throughout a great deal of this work. Several departments are carrying on work of the same character which, logically, should be under one head. As a result, there is a duplication of staff and equipment. Petty jealousies arise between the different departments, and there is little incentive to consistent and loyal work on the part of the individual members.

Evolu, in his article on "A National Board of Engineering Control," suggests the appointment of a board of control directly responsible to Parliament. All work of the same nature would logically come under one department and under one man. Increased efficiency would, no doubt, result, and the present lack of cohesion among the various departments, due to the overlapping, lack of responsibility and lack of system, would be obviated. The combining under one management of the work common to several branches would result in the work being done far more cheaply and economically than under the present system.

Probably one of the greatest improvements which would come as a result of the appointment of such a board of control would be the removal of all appointments from the sphere of politics. Appointments would be based strictly upon experience and ability.

There is no logical reason why the work of the government should not be carried on as economically and efficiently as that of a private organization. Until some such method is used, however, as is outlined in these articles, the present state of affairs will continue. It is to be hoped that this move on the part of Mr. Casgrain will be instrumental in drawing the attention of the public to the present state of affairs.

A PROSPECTIVE COURSE OF CERAMICS IN UNIVERSITY OF TORONTO.

The Canadian Clayworkers' Association, meeting in Toronto Tuesday, Wednesday and Thursday of last week, have revived with renewed vigor a movement to establish in the Faculty of Applied Science and Engineering, University of Toronto, a course in Ceramics.

This movement on the part of the executive is the result of a deeply-felt need experienced by the manufacturers of clay products for technical knowledge of the properties of the raw materials, and for more scientific methods in the process of manufacture.

No sooner had it been decided to take steps in this direction than a United States brick machine company

came forward with an offer to furnish any Canadian university disposed to inaugurate such a course with a fairly complete laboratory equipment consisting of a brick machine, grinding-pans, automatic cutter dies, and other necessities.

The president and the Board of Governors of the University of Toronto have expressed their sympathy with the desire of the Canadian Clayworkers' Association for the founding of a course in Ceramics. President Falconer, as the representative of the Board, stated that it was entirely a question of funds, and he impressed upon the deputation which waited upon him the necessity of bringing the matter before the Provincial Government in order that funds might be provided for such a course.

It is vitally important to the clayworkers' industries of the Province of Ontario, and, in fact, of the Dominion of Canada, that a department of Ceramics should be founded in the immediate future. The Provincial Government must not withhold the requisite aid for technical instruction in one of the most important industries of the Province.

TORONTO'S WATER SUPPLY.

Our criticisms of the report of the Board of Water Commissioners are not based on the question of the possibility of water not being able to run down hill or, as put by Mr. Randolph, on the question of the suspension of the law of gravitation, but on the question of hydraulic design, and economical construction, maintenance and operation.

Since our last issue appeared, one of the Commissioners, Mr. T. Aird Murray, has written to the Board of Control to state that his opinions regarding the feasibility and desirability of the Scarboro scheme had changed since he signed the report. He stated that he had serious doubts from the first, and he now withdraws from responsibility for the report. If Mr. Murray devoted so little time and attention when the report was being compiled that he did not fully appreciate what he was recommending, and if his attitude is typical of the other members of the Commission, certainly very little reliance can be attached to the report. His belated objections to their recommendations are based on facts of which, he says, he was cognizant during the compilation of the report; therefore, his conclusions as now presented to the Board of Control are diametrically opposite to those for which he received his fee.

It is only fair to *The Canadian Engineer* to state that the criticisms of the Scarboro water scheme which appeared some two weeks before Mr. Murray's letter to the Board of Control are not those on which Mr. Murray bases his objections to the report.

Our objections to the location may be summarized in very few words: The quality of the water is no better than that of Centre Island, and must be continuously filtered. There will be a greater first cost of construction; greater continuous cost of operation; greater cost of maintenance; and the lack of flexibility of the gravity scheme as compared with direct pumping.

For the benefit of the daily press in Toronto, which appear to feel that the question at issue is whether the water will flow down hill from Scarboro or not, we would like to call attention to an article which appeared in the January 9th issue of *The Canadian Engineer*, describing the Los Angeles Aqueduct. The length of this aqueduct, which supplies water for the city of Los Angeles, a municipality of 400,000 population, is 234 miles, and the fall is 1,500 feet. There are many other gravity systems in successful operation, but this particular Scarboro scheme is criticized in connection with the local conditions.

Our objections to the report are based on the fact that we do not believe that the Board of Water Commissioners have presented a practical plan.

Commissioner Harris has stated that the by-law to provide the requisite funds for the construction of a duplicate water supply was intentionally worded in such a way as to leave the choice of location and the details of design open. We have every confidence that Commissioner Harris, before he proceeds with the construction, will thoroughly investigate the whole situation and base his decision on the principles of engineering economics and design. To make his decision, he does not need the arguments of certain of the commissioners in favor of the Scarboro location (arguments which should have been presented with their report) or the repudiation of the recommendations in the report (a repudiation which should have been presented as a minority report) by the Commissioner who has changed his mind.

EDITORIAL COMMENT.

Do not forget the Annual Meeting of the Canadian Society of Civil Engineers in Montreal next week.

* * * *

The description of the plant of the Mississippi River Power Company in this issue will, we are sure, be of interest to all our readers.

OZONE TREATMENT OF WATER.

In some of the larger European cities the water supplies are sterilized by ozone treatment used as the sole means of purification or in conjunction with filters. The largest installations in which ozone is employed are the following:—

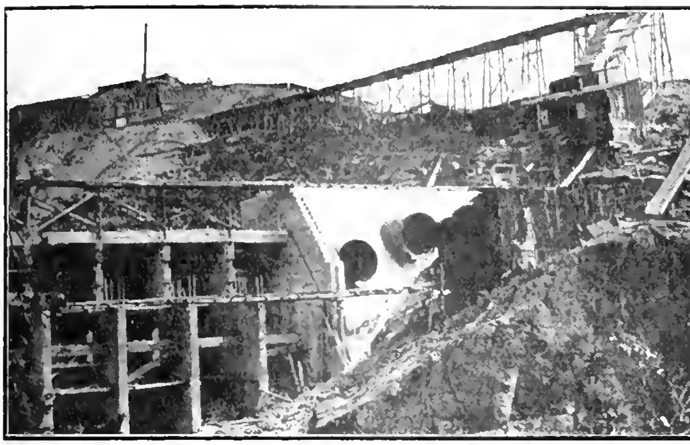
Locality.	Capacity, gallons per day.
St. Maur, Paris	13,000,000
St. Petersburg	11,000,000
Nice	10,000,000
Wiborgen	2,640,000
Florence	1,100,000
Wiesbaden	660,000
Hermannstadt	880,000
Chartres	325,000

There are also two new plants supplying the city of Paris which will have a total capacity of 12,000,000 gallons per day.

In America little progress has been made in the use of ozone owing primarily to its excessive cost. In the European plants the average cost of treatment is $10 per million gallons. The hypochlorite treatment in this country offers opportunity for efficient sterilization without an excessive outlay. Recently, however, a small plant at Great Falls, S.C., with a capacity of 80,000 gallons per day, has been installed, and it is claimed that the cost of treatment does not exceed $5.00 per million gallons. The principal objection to the ozone treatment has been its excessive cost and if this objection can be met it may be expected that the use of ozone will greatly increase.

HYDRO-ELECTRIC DEVELOPMENT ON THE MAGPIE RIVER.

About fifteen miles north of Michipicoten, in the province of Ontario, a dam has been constructed on the Magpie River, just above the falls known as Steep Hill Falls; the object being to develop electric energy for the use of the iron mines belonging to the Algoma Steel Corporation, of Sault Ste. Marie. The distance from the Helen mine is about five miles, and from the Magpie mine, twelve miles. A wood-pole transmission line, designed for an ultimate pressure of 22,000 volts carries the three-phase aluminum conductors from the power station to the mines. The pressure, in the first instance, will be 11,000 volts, and generators wound for this voltage will be connected directly to the line. If it is desired to step-up to the higher pressure at a later date, transformers with a ratio of one to two will be installed. The step-down transformers at the mines are suitable for either 11,000 or 22,000 volts on the primaries, with a secondary pressure of 600 volts.



Down-Stream View of Dam, Showing Position of Steel Penstock.

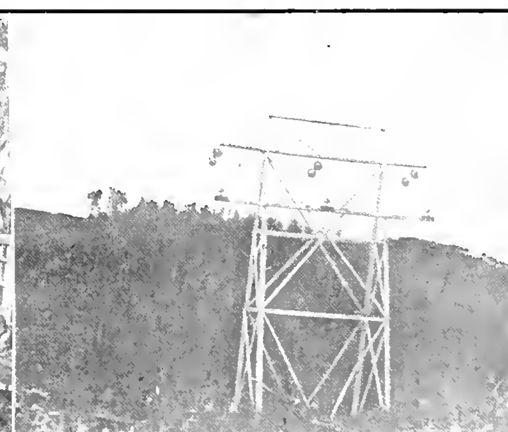
View Looking Down-Stream During Construction.

The dam, which is now completed, is of the Ambursen type, built of reinforced concrete with buttresses spaced twelve feet apart, supporting deck slabs tapering in thickness from 30 inches at the bottom near the cut-off wall, to 17 inches at the top. The height of the spillway above river bed is 45 feet and the total length of spillway is 145 feet; the overall length of the dam being 230 feet. There are 2,800 cubic yards of concrete in the dam, the mixture being 1 part cement, 2 parts sand, and 4 parts crushed rock in the cut-off walls, decks and spillway; while a 1:3:6 mixture is used in the buttresses and the solid work at both ends of the dam. About 65,000 lbs. of reinforcing steel, mostly in the form of ⅞ in. square bars, are imbedded in the concrete of the dam.

The dam is so constructed as to allow of the height being raised another 12 feet at a future date. With the spillway at its present elevation, the reservoir created on the upstream side of the dam is of negligible capacity, and is practically useless for storage purposes, the power available for a continuous supply of energy being determined by the quantity of water available at times of minimum flow.

Much of the concrete work on the dam was put in during the winter months in the early part of 1912, and as the winter temperatures in this district north of Lake Superior are very low, great care had to be exercised to prevent the too rapid cooling of newly placed concrete. During the months of January and February the thermometer very frequently stands at 40 degrees below zero, and temperatures between 50 and 60 degrees below zero were actually recorded. The water, sand and rock were steam heated, and after the concrete was placed, it was covered with canvas and every possible means employed to maintain it above freezing point until it had set. Under such conditions the forms have to be left in position considerably longer than when the concrete is placed under ordinary conditions. It is, however, a notable fact that the concrete put in during the cold weather was generally satisfactory.

Eight-foot Steel Penstock from Power House Site.



Steel Tower Supporting 1,000-ft. Span Over Ravine.

The total head available for driving the turbines is in the neighborhood of 60 feet. The power house, now nearing completion, is situated at the foot of the falls. It is being equipped with two turbines of the horizontal type, supplied

by Messrs. Hamilton and Company, Peterborough. These will develop 1,000 h.p. each and will be direct coupled to three-phase generators supplied by the Crocker-Wheeler Company, of Ampere, N.J., and designed to develop 900 k.v.a. at 11,000 volts, when running at 400 revolutions per minute. The continuous current for the generator fields is provided by a separately driven exciter, direct coupled to a water turbine supplied by the Rodney Hunt Company. The switchboard is supplied by Ferranti, Limited, of Manchester, England, and it provides for the hand operation of oil type switches on generators and feeders, through a simple system of levers.

The elevation of turbine shaft above low-water level in the pool at the foot of the falls, is 21 feet; but in seasons of flood, the water in the lower pool may rise as much as 8 feet. The water is brought to the turbines through a steel penstock 240 feet long, taken down the side of the river bank through a channel cut in the rock; the difference of elevation between top and bottom ends being 43 feet. Provision has been made for two penstocks, but one only is necessary for the operation of the 2,000 h.p. plant at present being installed.

The intake is closed by racks consisting of bars ¼ in. thick, spaced 1 9/16 in. apart, the total area of rack being 230 square feet.

The penstock, where it is built into the dam, is 8 feet in diameter, made up of ¼ in. steel plates which are increased to ⅜ in. at the bottom near power house. Just outside the power house, the pipe divides into two 6 ft. branches leading to the turbines. A surge tank is also provided at this point. It measures 12 ft. diameter, and has a total height of 80 feet, which brings the top of the tank 26 ft. above the level of the present spillway. The surge tank is built up of riveted steel plates 7/16 in. thick at the bottom, reduced to ¼ in thick at the top.

Two separate three-phase circuits leave the generating station. These are carried together on one set of poles for a distance of about 1¼ miles, where they branch off; one line going south to the Helen mine, and the other going north to the Magpie mine.

Three-phase current is used almost entirely at the Helen mine, not only for the main hoisting engine, but also for the various motors driving crusher, air compressor, conveyers, pumps, etc., both on the surface and below ground. At the Magpie mine, where the most up-to-date machinery is being installed, including a large travelling bridge for the handling of the ore, together with gas generators and complete calcining and roasting plant, a portion of the three-phase current, after being converted to 600 volts pressure, is used for driving a motor generator to provide continuous current for the motors on the ore bridge and other purposes.

The address of Dr. Allen J. McLaughlin, assistant surgeon of the United States Public Health Service, Washington, D.C., last month before the annual meeting of the Association of Life Insurance Presidents, on "The Effect of Safe Water Supplies on the Typhoid Fever Rate," was illustrated by a series of ten charts. Dr. McLaughlin presented an interesting comparative table showing the contrast between the typhoid mortality of fifteen of the largest American cities and fifteen of the largest cities of Europe. The lowest typhoid death rate abroad was 1.3 per 100,000 of population in Edinburgh, and the highest 5.6, in Paris. The lowest death rate from typhoid in American cities was 8.8 per 100,000 of population in Cincinnati, and the highest, 58.7, in Minneapolis. The Philadelphia mortality is 17.5 per 100,000, and that of Pittsburgh, 27.8.

STREET CLEANING IN PORT ARTHUR.

By W. S. Bowden, Street Commissioner.

The proper cleaning of paved streets has become a necessity. Vast sums of money are being spent every year by almost every town and city in Canada in the construction of high-class pavements designed to improve their principal streets, and business centres. And no municipality that has undertaken to improve and beautify their city this way, for the convenience and benefit of their citizens and the public generally, can possibly afford to overlook the great importance of this work. In fact it is frequently the case that a town or city gets its reputation from the condition of their streets; for beauty and cleanliness are qualities which catch the eye of every visitor, call forth admiration of every tourist, and not infrequently make a lasting impression upon the minds of business men.

The cleaning of paved streets is necessary for the following reasons: The preservation of the public health; the physical comfort and convenience of the people, and due regard for decent cleanliness and good appearance. Sanitary authorities have for some time held that dirty streets are a prolific cause of disease, and therefore a menace to the public health.

And in the light of recent investigations the conclusions reached by the most eminent scientist in regard to the germ theory of the spread of disease, that nearly all infections or contageous diseases are caused directly or indirectly by specific organisms or their germs, which, being incorporated into or attached to some solid or fluid matter, are carried thereby into the body and to the blood, where they propogate and multiply, causing destruction and death. These conclusions have a very important bearing upon the theory and practice of street cleaning.

When the question of adopting a system of pavements for a municipality is first brought up for consideration it often happens that so much time and energy is devoted to preliminary investigations before a decision is made, that any arrangements for cleaning are neglected until after much construction work has been done. They are then often forced to make a hurried selection of equipment which may later prove to be a failure But, the expenditure having been made, they hesitate to throw it aside. This is one of the reasons why many places are not using the system best suited to do the work effectively. From the sanitary point of view, street dirt may be divided into two physical classes or forms: First, the comparatively fresh, coarse and recently deposited material that reaches the street; and second, the finely comminuted matter, which, when dry, is called street dust.

The views here outlined indicate the importance which is, or should be, attached to the selection of the equipment best suited to secure a frequent and speedy removal of the coarse material before it becomes pulverized and dry, and also to provide some satisfactory method of removing the fine dust that cannot be prevented. In order to do this work effectively one of the best methods that has so far been developed is the use of the hand cleaning patrol system, whereby the men with their carts and brooms are able to pass over their beat several times a day, and promptly, and frequently remove the coarse material, and by this method, if the work is done properly, from ninety to ninety-five per cent. of all the refuse matter and rubbish that finds its way to the street will be removed.

We now come to consider the removal of the fine dust which cannot be prevented, and this is most important. Assuming that this street dust is infected with disease germs,

and that if allowed to remain upon the street it will, by the action of the sun and wind and the pulverizing action of travel, be reduced to a condition of powder so fine and light that it will readily float in the air and be carried by the wind and breezes to a considerable distance, and while thus suspended it may be breathed into the lungs, or deposited upon the bodies of those in the vicinity. It is therefore most dangerous to public health.

For this part of the work the practice of flushing the streets with water under pressure using the street flushing machine is very successful. This is especially true where the proper system of catch basins have been provided to prevent the dirt being carried into the sewers. This is the system and method of doing the work that are in successful operation in the city of Port Arthur.

In the early summer of 1910 the city began the construction of high-class pavements, and by the end of June, 1912, there was laid and open for traffic 81,869 square yards. These pavements consist of five different kinds, viz., sheet asphalt, asphalt block, bitulithic, asphaltic concrete, granatoid or concrete. They are laid on eleven streets and total 3.165 miles. On one of these, which is about a mile in length and paved with asphalt block, there is operated a double track street railway. In cleaning these pavements we find that one man with a Menzie street cleaning cart, using an 18-inch broom, covers an average of 11,695 square yards per day. He wears the ordinary street suit and cap, and has two cans in connection with his cart, when one becomes filled he leaves it at the curb and proceeds to fill the other until the wagon comes to collect it. One man with team and dump wagon collects an average of 8 cubic yards per day, which has to be carted an average distance of one mile.

The sanitary automatic street flushing machine which is used to remove the fine dust, is operated by one man with team. The water for this purpose is taken from stated hydrants.

About thirty minutes are required to fill the tank of the flushing machine and discharge the contents upon the pavements. Each load contains about 480 Imperial gallons and flushes an average area of 2,000 square yards. In the most central part of the city the flushisg is done three times a week, and the remaining portion of the pavements are flushed one and one-half. times each week. No cleaning or flushing is done on holidays or Sundays, and the complete system of catch basins is cleaned five or six times during the summer season. Some extra work is done on Saturday night and on evenings before holidays. In this way the pavements are kept almost spotlessly clean.

The first cost of the equipment which we have in use was as follows:—

One automatic street flushing machine	$1,341.00
One dump wagon	180.00
Seven Menzie street cleaning carts (each with one extra can)	115 50
Seven 18-inch street brooms	7.30
Two street suits for each of seven men	49.00
Total	$1,692.80

The average daily cost for labor to do the work of hand cleaning with brooms and carts, flushing, removing the refuse and cleaning the system of catch basins in connection with the 81,869 square yards of pavement referred to, amounts to $26.00. This shows that under the local conditions as I have stated, and with the equipment referred to, the cost of cleaning one square yard of pavement is .003176 cents per day. Assuming that the streets are free from snow and require to be cleaned in the usual way for 240 days, the cost for the summer season would amount to 7.62 cents per square yard.

It might, however, be said that if the traffic was much heavier, as in very large cities, the cost would be considerably higher, but at present, with the limited area of pavements which we now have, there are 40 earth roads leading to them at various points. These roads, during the wet weather, are a source from which large quantities of mud are carried in upon the pavements by the traffic, and when it is considered that this is most difficult kind of dirt to remove, and that as the area of pavements is increased this source of trouble will become proportionately less, I see no reason to assume that the cost should be materially increased, even with heavier traffic.

KING EDWARD VII. HIGHWAY.

By H. S. Van Scoyoc,*

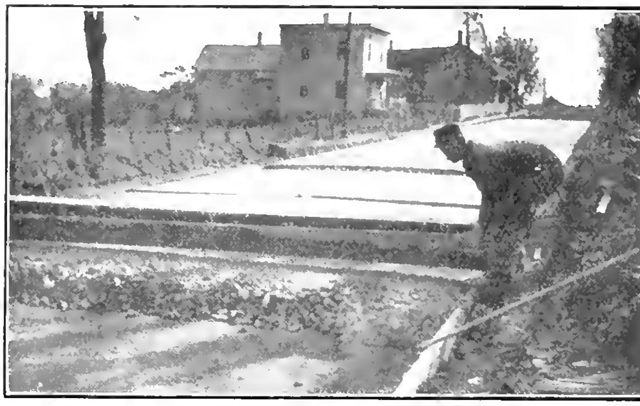
Unquestionable proof of the interest which is being taken in permanent road construction throughout the Dominion is shown by the fact that on the Western coast many miles of the Canadian portion of the Pacific Coast Highway, which will eventually join Mexico with the Yukon, have already been built. In addition, the Western and the Prairie Provinces have completed a number of sections that will form portions of the proposed Across Canada Highway. In Ontario, the completion of the Toronto to Hamilton Road is only a question of time, the portion leading from Toronto through York County having already been built. Quebec has maintained a foremost position in the Good Roads movement, and possibly its most interesting project has been the building of the Canadian portion of the International Highway which will join the city of Quebec on the north with Miami, Florida, on the south. Tenders have recently been requested on that portion of the road which will connect Quebec with Montreal, and it is planned to do as much as is possible of the actual work during the coming season.

That portion of the International Highway which extends from Montreal, Que., to Rouses Point, N.Y., is known as the King Edward VII. Highway, and it had been hoped that this road would be completed during 1912. The very bad season made this impossible, however, and when work was discontinued last fall, approximately one-half of the work remained unfinished. The original plan called for macadam construction, but it was modified to the extent that the portion passing through Napierville was built of concrete. It is the purpose of this article to take up in detail the methods used in the construction of the concrete portion.

The soil in this vicinity is a clay with occasional stretches of sandy loam. Drainage was provided by the construction of open ditches, the bottoms of which were about two feet below the sub-grade. In the village proper, the ditches were filled with large stone, and the stone covered to provide space for sidewalks. In general the grade of the finished roadway follows the surface of the old road so that the amount of either cut or fill was practically negligible. The concrete portion of the road is 16 feet wide, and the excavation was of this width and of such a depth that after thorough rolling with a ten ton roller the sub-grade was parallel to the surface of the finished road, and seven inches below it.

*Inspecting Engineer, Canada Cement Company, Limited. Associate Member American Society of Civil Engineers.

On the sub-grade, prepared in the manner described above, 2 x 7 inch planks were placed on edge 16 feet apart, inside to inside, and held in position by iron pins driven into the sub-grade on either side of the planks. Concrete in the proportion of one part cement, two parts sand and four parts broken stone, mixed in a batch mixer and of a rather wet consistency was then placed to a thickness of seven inches and brought to grade and given the proper shape by means of a strike-board or template. The template was cut to give the road a crown of 2 inches in 16 feet and was made from 2 inch planks. The curved edge was protected by a steel plate and the finished template rested on the side planks as shown in the accompanying photographs. To properly shape the concrete, two men, one at either end, slowly moved the template towards and away from each other, and at the same time, slowly moved it forward. In some cases an up and down motion was used to bed the larger stone in the motar. The template was kept approximately at right angles to the centre line of the road.



Crowning Road with Template, Napierville, Quebec.

The Road Completed.

After the road had been brought to shape no one was allowed to walk on the concrete or disturb it in any manner, and all subsequent work was done from a bridge which was clear of the road and rested upon the side forms. The finishing was done by two cement workers with wooden floats, who worked from the bridge. Great care was used to prevent any depressions in the surface, as it was realized that wear on the surface would be reduced to a minimum if this was accomplished.

Each day's work was covered at night with a tarpaulin and when the concrete was hard enough, the tarpaulins were removed and a covering of two inches of dirt from the sides of the road was placed on the concrete to prevent its drying out too rapidly. It was allowed to remain for two weeks before being removed. The intention had been to sprinkle the dirt each day to keep it damp, but there was so much rain that this was found unnecessary. The rainy weather also kept the sub-grade moist so that it was not sprinkled before the concrete was placed.

Transverse contraction joints were made every twenty-five feet at the time the concrete was placed. The earlier joints were made by means of steel plates 3/8″ thick at the top and 1/4″ at the bottom. The plates were held in position by iron pins driven on either side. When concrete had been placed on both sides of the plates, the pins were withdrawn. After the concrete had set sufficiently the plates were removed and the edges of the joints were rounded to a radius of a quarter of an inch and were tooled down hard and smooth; these joints were afterwards filled with asphaltum.

In the later construction the joint was made in a different manner. A piece of tarred roofing paper was folded around the plate and the whole kept in position as before, but when the concrete had been deposited about three feet beyond the joint, the plate was withdrawn and the concrete tamped against both sides of the tarred paper, closing the space left by the withdrawal of the steel plate. In this way a very narrow joint was made with less trouble and expense, for the filling with asphaltum was avoided, and the steel plate was withdrawn much more readily than when the concrete set up in contact with it. Whenever it was found necessary to discontinue work for any reason, a vertical joint was made. Whenever possible work was stopped at one of the regular contraction joints.

After the concrete had thoroughly hardened, macadam shoulders, four feet in width, were built on either side of the concrete, making the finished roadway twenty-four feet over all. Traffic was not permitted on the road until the concrete had been down for at least three weeks.

DRY DOCK FOR MIDLAND.

A floating drydock and building berth will be constructed by the Midland Drydock Company, Limited, at Midland, Ontario. Among those interested in the enterprise are Mr. James Playfair, Mr. D. L. White, Mr. D. S. Pratt and other residents of Midland. The town has granted a bonus of $25,000 to the company, as it is anticipated that the undertaking will cause the expenditure of large sums of money in the town, give employment to a considerable amount of labor and tend to assist and encourage the marine trade in the port of Midland. The town will issue debentures for the purpose. It has made an agreement with the drydock company and with the Canadian Dredging Company, Limited, by which the plant will be erected for the construction and repair of steel and wooden vessels.

The dock will be built in separate units, the first unit having a length of 150 feet by a beam measurement of 72 feet, and having a lifting capacity of 1,200 tons. The first unit is to be constructed and ready for operation before September 1, 1913, and the second unit by May 1st, 1915. The company will operate their machinery by electric power, purchasing the power from the town, which has agreed to place a fixed assessment on the company's property. Mr. H. Calderwood has prepared the plans for the drydock and building berth.

Midland is in Simcoe County, on Mundy's Bay, an arm of the Georgian Bay, and on the Grand Trunk Railway, 32 miles north-west of Orillia, and 120 miles north of Port Hope. The population of the town is about 4,600.

GREATEST PIER REACTIONS DUE TO LIVE LOADS.

By S. J. Glaser.

In figuring the bearing on foundations of bridge piers, it is necessary, among other things, to find the maximum reaction due to live loads acting on the two adjacent spans.

The accompanying table gives the values of the maximum reactions for any combination of two adjacent spans, varying from 50 to 130 feet in length at five-foot intervals. These spans are most usual for plate girder bridges. The values above the heavy zig-zag line running through the table are for class I., and below for class heavy loading, Dominion Government specifications.

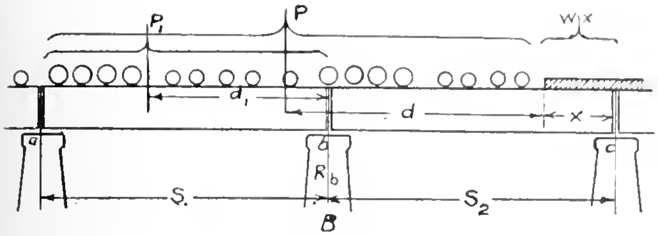


Fig. 1.

To obtain the value of the maximum reaction for any two spans, the larger span should be looked for in the first or last vertical column, depending respectively on whether class I. or class heavy loading is used.

A series of curves can be platted from the values found in the table and the greatest pier reactions for intermediate spans can be obtained. It will also be found that the lower part of the curves are straight lines, and when these lines are produced values sufficiently correct for spans less than 50 feet can be mechanically obtained. Such span lengths are frequently used for steel viaduct bridges.

The values in the table may be enterpolated for intermediate spans in a horizontal direction for the variations are proportional.

The method of obtaining the greatest pier reactions due to live load is as follows: The load on any pier is the sum of the reactions at the end of the adjoining spans. In Fig. 1 the reaction of pier B, due to live load, is equal to the sum of the right reaction of span ab and left reaction of span bc.

The criterion of loading giving the greatest value of this sum is similar and is derived in the same way as that for maximum floor beam loading.

Letting P, (Fig. 1) be the load on the span ab, d, the distance of its centre of gravity to the right end of the span, and letting P be the sum of the concentrated loads of the typical consolidation locomotives on both spans ab and bc, and d the distance of its centre of gravity to the head of the train, whose weight is w pounds per linear unit. The total live load on the span is $P + wx = W$. Let Rb be the combined reactions of the two adjoining spans, of lengths S_1 and S_2. An expression for Rb can be obtained. Placing the dirivative of this expression equal to zero, also substituting for $P + wx = W$ we get

$$\frac{W}{P_1} = \frac{S_1 + S_2}{S_1} \qquad (1)$$

or the loads should be proportional to the lengths of the spans is the criterion to make the value of Rb a maximum.

When $S_1 = S_2$ the criterion becomes $W = 2 P_1$ (2)

Care must be used in applying these criterions. Since the concentrated loads are not uniform the loading to give a maximum should be so apportioned that a heavy driver is at b and as large a load brought on the two adjoining spans as possible.

In figuring the reactions from a moment diagram it may be arranged more conveniently as follows: Let Mc equal the moment of the loads in both spans about c and Mb equal the moment of the loads in span S_1 about b, then

$$Rb = \frac{M_1 S_1 - Mb (S_1 + S_2)}{S_1 \times S_2} \qquad (3)$$

This becomes $Rb = \dfrac{Mc - 2 Mb}{S}$ (4)

for two equal spans of length S.

For two unequal spans with train running in either direction there will be two maximum reactions. It can easily be shown from (3) that the greater maximum value of Rb will be obtained when S_2 is the smaller span and train running in direction shown in Fig. 1.

Table Showing Maximum Pier Reactions Due to Live Load for One Rail for Class I. and Class Heavy Loading, Dominion Government Specifications, Values Given in Kips.

Class Heavy	Maximum Pier Reactions — Class Heavy — Dominion Government Specifications																	Class I

CANADA'S STEEL INDUSTRY

The production of steel ingots and castings in 1911 was 882,396 tons, as compared with 822,284 tons in 1910 and 754,719 tons in 1909. In 1911 the production of open-hearth ingots was reported as 651,676 tons; Bessemer ingots, 209,817 tons; direct open-hearth castings, 20,163 tons, and other steels, 740 tons. The total increase in production over 1910 was 60,112, or a little over 7 per cent. The production during the five years, 1907-1911, follows:—

	1907. Tons.	1908. Tons.	1909. Tons.	1910. Tons.	1911. Tons.
Ingots — Open-hearth (basic)	459,240	443,442	535,988	580,932	651,676
Bessemer (acid) ...	225,989	135,557	203,715	222,668	209,817
Castings—Open-hearth	20,602	9,051	14,013	18,085	20,163
Other steels	1,151	713	1,003	599	740
Total ...	706,982	588,763	754,719	822,284	882,396

Statistics showing the quantities of the principal materials used in steel furnaces were obtained for the first time for the year 1910, and it may be of interest to refer to these here. The total quantity of pig iron used in steel furnaces during 1911 was 700,679 tons, of which 640,636 tons were produced by firms reporting, and 60,043 tons purchased. The quantity of ferro-alloys used was 21,359 tons purchased. Scrap, etc., was used to the extent of 278,797 tons, being 198,482 tons produced by the firms reporting, and 80,315 tons purchased. Ores used included 829 tons of manganese ore and 42,892 tons of iron ore, while 130,270 tons of limestone or dolomite flux were used and 8,067 tons of fluorspar. In Ontario a little over 662 million cubic feet of natural gas were used, while in Nova Scotia coke oven gas was used at Sydney, of which a record of quantity is not obtained.

In 1910 the total quantity of pig iron used in steel furnaces was 690,913 tons, of which 601,219 tons were produced by firms reporting, and 89,694 tons purchased. The quantity of ferro-alloys used was 8,143 tons purchased. Scrap, etc., was used to the extent of 211,453 tons, being 140,913 tons produced by the firms reporting and 70,540 tons purchased. Ores used included 1,317 tons of manganese ore and 30,332 tons of iron ore, while 144,110 tons of limestone or dolomite flux were used and 7,461 tons of fluorspar. In Ontario a little over 600 million cubic feet of natural gas were used.

Statistics of the production of steel ingots and castings since 1900 are given in the following table:—

Calendar year.	Short tons.	Calendar year.	Short tons.
1900	26,406	1906	639,396
1901	29,214	1907	706,982
1902	203,881	1908	588,763
1903	203,296	1909	754,719
1904	166,381	1910	822,284
1905	451,863	1911	882,396

Mr. J. McLeish, chief of the division of mineral resources and statistics, shows that while complete statistics of the production of rolled products and of manufactured steel were not available, returns from seven of the largest producers showed a production of blooms, billets, slabs, etc., of 737,261 tons, of which 719,514 tons were used by the producer for further manufacture, and 17,747 tons sold to other rolling mills.

The production of rails was 309,760 tons; of rods, 85,811 tons; of bars, 109,623 tons, and of other rolled products, 65,076 tons. The production of steel rails in 1910 was returned as 300,762 tons, and in 1909, 377,642 tons.

The production of finished rolled iron and steel in Canada from 1909 to 1911, as ascertained and published by the American Iron and Steel Association, was as follows, in long tons:—

	1909.	1910.	1911.
Rails	344,830	366,465	360,547
Structural shapes and wire rods	74,136	80,993	76,617
Plates and sheets	36,241	26,642	14,833
Nail plate, merchant bars, and all other finished rolled forms	207,534	265,711	323,427
Total	622,741	739,811	775,424

Since 1896 a total of $16,785,827 has been paid by the government of Canada in bounties for the production of iron and steel.

The total value of iron and steel goods, including agricultural implements, automobiles and bicycles, exported from Canada during 1911 was $9,907,281, as compared with a value of exports in 1910 of $7,895,489, and in 1909 a value of $7,172,413. Of the total exports in 1911, stoves, gas buoys, castings, machinery, and hardware contributed a total valuation of $1,242,006; pig iron, $271,968; scrap iron and steel, $54,618; steel and manufactures of steel, $769,692; agricultural implements, $6,281,929, and automobiles and bicycles, $1,287,068. Particularly large increases are noted in the exports of agricultural implements and of automobiles and bicycles.

The total value of the imports during the fiscal year ending March, 1911, was $85,319,541, as compared with the valuation of imports in 1910 of $59,952,197, and $40,393,431 during the fiscal year 1909. These imports include all classes of iron and steel goods manufactured, as well as those of a crude form. In many cases the imports of manufactured goods are given only in dollars, so that the total tonnage of imports cannot be estimated. In the case of most of the cruder materials, however, the quantities are given, and a compilation of these shows a minimum importation of iron and steel during the fiscal year ending March, 1911, of 1,284,401 tons, as compared with 915,425 tons in 1910 and 565,734 tons in 1909.

The record shows an importation in 1911 of ingots, blooms, billets, puddled bars, etc., of 48,395 tons; scrap iron and scrap steel, 53,824 tons; plates and sheets, 205,690 tons; bars, rods, hoops, bands, etc., 183,865 tons; structural iron and steel, 345,350 tons; rails and connections, 36,690 tons; pipe and fittings, 28,831 tons; nails and spikes, 3,099 tons; wire, 64,850 tons; forgings, castings, and manufactures, 24,523 tons.

The total value of the 1,284,401 tons imported was $33,766,865, or an average value per ton of $26.29. Other iron and steel goods of which the weights are not recorded were imported to the value of $51,552,679, making up the total value of $85,319,541.

A very large proportion of these imports is derived from the United States, and it may be of interest here to quote from the records published in the "Commerce and Navigation of the United States," showing the exports of iron and steel goods from that country to Canada.

According to this authority there was exported to Canada from the United States during the twelve months ending June 30th, 1911, 821,526 tons of iron and steel goods, valued at $25,544,421, together with other iron and steel goods of which the weight is not given, valued at $38,738,575, or a total value of $64,282,996.

During the twelve months ending June 30th, 1910, the corresponding exports to Canada were 574,807 tons, valued at $19,673,740, together with other iron and steel goods to the value of $28,153,628, or a total value of $47,827,368. Iron ores are not included in either case.

The imports of some iron and steel products of which the weights are available follow:—

Material.	Twelve months ending March.	
	1910.	1911.
	Tons.	Tons.
Pig iron	159,506	270,102
Ferro-products and chrome steel	15,153	19,182
Ingots, blooms, billets, puddled bars, etc.	36,819	48,395
Scrap iron and scrap steel	28,797	53,824
Plates and sheets	200,575	205,690
Bars, rods, hoops, bands, etc.	117,159	183,865
Structural iron and steel	195,748	345,350
Rails and connections	55,183	36,690
Pipes and fittings	16,705	28,831
Nails and spikes	3,476	3,099
Wire	68,211	64,850
Forgings, castings and manufactures	18,003	24,523
Total	915,425	1,284,401

ENGINEERING AND THE BEAUTIFUL.*

It is an idle platitude to state that the present is an age of specialization, for no man can say as Lord Bacon did: "I will take all knowledge to be my province." Even the most versatile engineer can attempt to master but one branch of his profession, although collectively the engineers' achievements have changed the whole aspect of modern civilization. If we cast our minds back to-night to, say, the new year 1813, what a fascinating kaleidoscope it makes, especially to us on the Pacific slope, when we try to realize what has been accomplished in that country of progress, and then contrast the material progress that had been accomplished up to that time from the days when the architects Ictinus and Callicrates collaborated with Phidias, to produce the beautiful Parthenon, one only of many beautiful structures which the Greeks so magnificently created more than two thousand years ago.

The engineer of the past century has been a powerful and beneficial revolutionist, and his successful revolutions have instituted many reforms that have accomplished more for the well-being of the human race than most of the boasted achievements of contemporary wars and political agitations.

But, with all our progress, proud though ye may be, is it not well to remember that because the work of the engineer forms a vital and integral part of the life of any community, we should all pay some regard to the creation of beauty and the influence of engineering upon the minds of the people.

Ruskin's well-known aphorism on architecture might have some meaning for us as engineers; he defined it, you may remember, as "the art which so disposes and adorns the edifices raised by man, for whatsoever uses, that the sight of them may contribute to his mental health, power and pleasure."

Engineers are usually regarded as estimable utilitarians who, by their works, enable continents to be crossed in comfortable cars, who control rivers, build harbors and docks, develop water powers by converting the rain and snow of the upper mountains into electrical energy, do much toward conquering time and space and invent wonderful machines for the general advancement of the people, but who are not primarily concerned with beauty or the creation of beautiful objects.

In olden days engineering and architecture were practised by the same individuals. The old Roman engineers, designers of the Pont-du-gard and the Claudian aqueduct, produced great engineering works that are among the finest architectural remains of that great race. In the rennaissance period were not the great artists Michael Angelo, Leonardo-da-Vinci and Palladio great both in architecture and engineering? Modern engineering, though, with all its mighty achievements, is still in the early pioneer stage, while the traditions of architecture are hoary with the experience of ages.

Engineering structures in steel have been accused of being purely utilitarian, and even William Morris denounced the famous and, as many of us think, beautiful Forth Bridge as "that supreme specimen of all ugliness." But Morris did not understand as the designers did, that their "object had been to arrange the leading lines of the structure so as to convey an idea of strength and stability," and that object they had considered the highest art. On the other hand, a famous artist—Alfred Waterhouse—writing to Sir John Fowler after the bridge was completed said:

"The simple directness of purpose with which it does its work is splendid, and invests your vast monument with a kind of beauty of its own, differing though it certainly does from all other beautiful things I have ever seen."

We cannot yet expect that a well-designed steel structure will be properly appreciated as stone structures have been. Let us remember that the Parthenon was built during Pericles time, when Greek art and literature reached its proudest zenith, but that great period was preceded by centuries of strenuous effort and experience; while steel structures belong but to yesterday, and many new and more perfect types remain to be evolved in the future. It is therefore unfair to apply the same standards of criticism to a modern steel structure as would be applied to one of wood, brick or stone.

The evolutionary process that is apparent in the design of modern steel structures, to use Herbert Spencer's line of progress in organic evolution is from "simplicity to complexity of structure, and from obscure complexity to a defined simplicity of function," and this "simplicity of function" should be the prevailing note in all well-designed structures to-day. Michael Angelo maintained that an architect should have a knowledge of anatomy; cannot we also boldly assert that to those who examine iron and steel structures from an aesthetic point of view, that a knowledge of their anatomy and of the functions of their various parts is essential?

What I really want to urge is that it is essential to-day that there should be greater co-operation between engineers and architects. Engineers have no right to load their structures with architectural decoration that they do not understand. "I love a sufficient man," said Emerson, "he meets my needs," but we cannot to-day, in the infinite variety of duties an engineer is called upon to perform, produce the "one sufficient man" for a great engineering structure. It takes the engineer the greater part of a busy life to master even one branch of the profession, and it takes the whole of an architect's life to understand his art. I am, therefore, advocating the co-operation of engineers and architects in the design of engineering works; these works are primarily for the use of the community, and in many cases, such as in the building of great masonry dams which may last for many centuries, we have no right to inflict ugliness upon the present and coming generations, especially as a beautiful design generally costs no more to construct than an ugly one, and not infrequently costs less.

One almost hesitates to suggest, in these days when the young engineering student's college curriculum is so crowd-

* An address delivered at the year end dinner of the Pacific North-West Engineering Society, Seattle, January 4th, 1913, by G. R. G. Conway, M.Inst.C.E., M.Am.Soc.C.E., M.Can.Soc.C.E.

ed, that a part of his training should be to acquire some knowledge of classic architecture. To appreciate the proportions of an old Greek temple is part of a liberal education, and in after life it might prevent the engineer from placing meaningless ornament upon his designs, and lead him in all humility to seek advice from the members of his brother profession.

That versatile and eminent English engineer, the late Sir Benjamin Baker, used to tell a story of how, when he was very young he thought he could do without architects, and how he had carried out what he thought was some very pretty work. There had been scrolls and columns and arches in iron work, and John Ruskin said when he had seen it that he wished that he had been born a blind fish in a Kentucky cave!

To-day, I think, we can point to many fine works that have been constructed on the American continent and in Europe, where engineering works have a magnificent and beautiful appearance. There is great scope in the building of masonry and concrete dams, and this has been well carried out in the Croton Dam for the water supply of New York, and in the dams for the supply of water to the cities of Liverpool and Birmingham. We see the co-operation of engineers, sculptors and architects in such beautiful bridges as the Pont Alexandre, in Paris, and in the great terminal railway stations of the Pennsylvania Railroad, the New York Central, the terminal at Washington, and the Orleans station at Paris; in power houses, Niagara and elsewhere, and in the general progress of town planning; and I might also further point out, the possibility of beautiful designs in reinforced concrete structures is being thoroughly appreciated.

In many cases, an engineer, be he the servant of a government, municipal or private corporation, must of necessity attain results by economy in design. In our new and developing towns on the Pacific Coast, it is not possible to do what is being done in older established communities. None of us believe that cedar poles with dozens of power wires strung on them along a public street are beautiful objects—unless seen in an etching by Whistler—but the public must always remember they belong to a transitional epoch when money is needed for necessary development, and distant shareholders have a right to the modest dividends they obtain from electric railway and power undertakings. The future, though, with the great growth of business, will make it necessary for all interests to place such wires underground, and then we have what is right from an engineering point of view, assisting in promoting the beauty of our towns.

Why should not even the humblest railway station be a beautiful object? We no longer believe in Ruskin's fierce denunciation of architectural railway stations, and in these days of constant travel, the comfort and beauty of a railway terminal is a delight to travelling man. Why cannot we have beautiful designs for the buildings and chimneys of a steam power plant, for a water tower, for all our bridges, for service reservoirs and valve houses? We should, though, in every case let these structures express by their design their meaning, stating plainly without pretension what they represent. We do not want a railway terminal to look like a temple for the worship of Minerva, or a steam plant chimney to resemble Cleopatra's needle.

Engineering touches every phase of our life, and it is clearly our duty to do all we can, not only to assist the material prosperity of our country, our state or province, but to contribute to all those things that elevate man outside of the strenuous every-day struggle for existence into a sphere that will enable him to appreciate the higher arts, and in that work the engineer can do his share in proving that the useful can also be the beautiful.

CANADIAN POTTERY

The pottery made from Canadian clays has been, hitherto, chiefly of the common grades, such as flower pots, jardinieres, crocks, jars, churns, etc. A number of potters make a higher grade product of stoneware, but the majority of these use imported clays. Sanitary ware is made at St. Johns, Que., and other points; but the raw material including clays and feldspar, is nearly all imported.

The total value of the production of pottery and clay sanitary ware in 1911, according to returns received, was $439,264, of which it is estimated that a value of $336,771 is attributable to imported clays. The value of the production reported in 1910 was $250,924, and in 1909, $285,285.

The total imports in 1911 were valued at $2,516,536, as compared with a value of $2,283,116 in 1910. These imports are subdivided into eight classes, and in 1911 include: brown or colored earthenware, etc., $52,100; C.C. or cream colored ware, decorated, printed or sponged, etc., $184,291; demijohns, churns, or crocks, $4,933; tableware of china, porcelain, white granite, etc., $1,718,582; china and porcelain ware, N.O.P., $62,025; tiles or blocks of earthenware or stone prepared for mosaic flooring, $123,203; earthenware tiles, N.O.P., $154,351; manufactures of earthenware, N.O.P., $217,051.

Great Britain is the principal source of the imports of this class of products, but quite large supplies are also obtained from the United States, Germany, France, Austria-Hungary, Japan, Belgium, and other countries.

Although there has as yet been no actual commercial production of china-clay or kaolin in Canada, the development of kaolin deposits in the township of Amherst, Ottawa county, and the construction of a washing or refining plant at St. Remi d'Amherst, are worthy of note.

The present operators are the Canadian China Clay Company, with a capital of $250,000. Mr. John C. Broderick, St. Remi d'Amherst, is mine manager, and Mr. Jas. G. Ross, B.Sc., consulting engineer.

The plant for refining the clay is situated two miles from St. Remi d'Amherst and seven miles from Huberdeau station, the terminus of the Canadian Northern Quebec Railway, 94 miles north-west of Montreal.

Development work was begun by the present operators in June, 1911, and the washing plant completed in April of 1912.

The clay is mined by digging, no drilling or blasting being necessary, trammed 600 feet to the plant, washed free from grit and allowed to settle. After the filter presses have extracted the surplus moisture, it is dried in the open air in stacks.

Dry kilns are being built for drying in the winter and wet seasons. After drying it will be pulverized and bagged for shipment. It is expected that an immediate market will be found in the demand of the Canadian paper mills.

The imports of china-clay, ground and unground, into Canada during the twelve months ending December 31st, 1911, were valued at $125,768, as against a value of $142,125 in 1910, and $100,066 in 1909, thus indicating to some extent at least the present actual demand for this product. The imports of earthenware and chinaware, however, valued at $2,516,436 in 1911, and composed chiefly of tableware of china, porcelain, etc., show the possibilities in the development of industries utilizing china-clays, suggests Mr. J. McLeish, chief of the division of mineral resources and statistics, in a recent report.

Kaolin or china-clay is also in considerable demand in the United States, the imports into that country in 1910 being valued at $1,593,472.

THE FILTRATION PLANT OF THE MONTREAL WATER AND POWER COMPANY AT MONTREAL, QUEBEC.

The Montreal Water and Power Company furnishes water to the outlying wards of the city of Montreal and to the cities of Westmount and Maisonneuve, and the town of Outremont, comprising in all, a population of about 250,000.

The water supplied consists of a mixture of St. Lawrence and Ottawa River water and is subject to marked seasonal changes in character. Normally, it is quite clear and free from turbidity or color. The alkalinity averages about 95 parts per million and the permanent hardness for incrustants about 20 parts per million. For a short period in the spring and autumn it becomes turbid and considerably colored. The bacterial content is never high, in fact it is abnormally low for water from a river of this character. A sterilizing plant has been in operation for over two years, and the water supplied has been satisfactory from a bacteriological standpoint to the Provincial Board of Health.

However, owing to an ever-increasing demand for filtered and colorless water, the company decided to install the present plant.

The filtration plant, which is of the so-called rapid mechanical gravity type, is situated near the main pumping station on the banks of the St. Lawrence River, at the southwestern city limit. It comprises low lift pumps, settling and coagulating basins, filter beds, clear water basin, wash water pumps, blowers, a storage tank for air and wash water, chemical mixing tanks and complete apparatus for handling sulphate of alumina and hypochlorite, a completely equipped chemical and bacteriological laboratory and a large chemical storage room.

All pumps, blowers, agitators and other machinery in the plant are operated by electricity and are all provided in duplicate.

The capacity of the plant is 25 millions of Imperial gallons per day, but provision has been made throughout for the extension when required to a capacity of 42 millions per day.

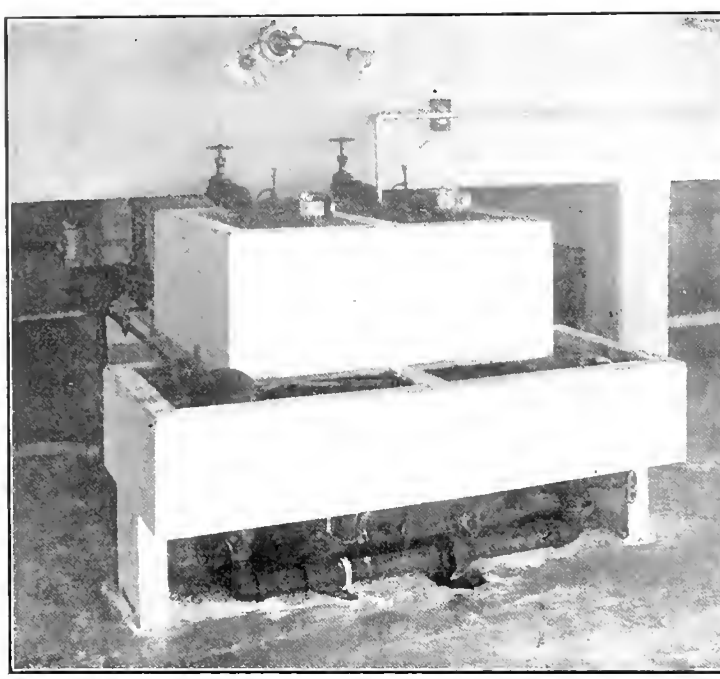
The river water flows by gravity into a suction well thirty feet in diameter and is pumped from this into the coagulating basin, from which it flows by gravity to the filters, through the filters to the clear water basin, and thence to the high lift pumps, which deliver it to the distribution system. This is shown in the diagram on the following page.

The raw water pumps are electrically driven turbine or centrifugal pumps operating against a total head, including suction and friction, of thirty feet, and discharge into a 60-inch steel main connecting to a concrete flume leading to the sedimentation and coagulating basins. At the inlet end of the basin is a float chamber, where the flow of water is automatically regulated by floats which operate throttle valves on each of the pumps. This is accomplished by means of hydraulic valves, the floats merely opening or closing small pressure valves which control the hydraulic valves.

The Building of the Filtration Plant, Montreal Water and Power Company.

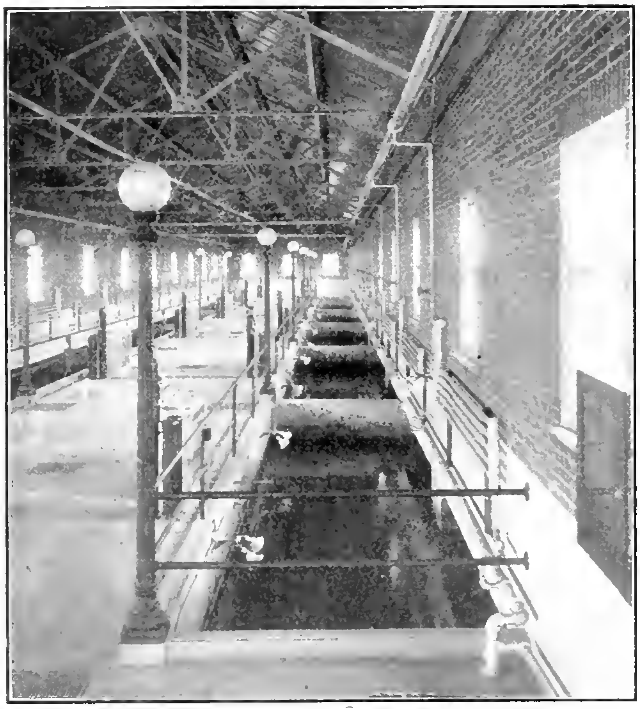
Settling Basins.—These are in duplicate, each holding about 500,000 Imperial gallons. They each measure 110 feet by 48 feet 6 inches in plan and are divided into two halves by longitudinal baffle walls which cause the coagulated water to pass the length of each basin twice before reaching the skimming weir at the outlet end. The basins are covered by a concrete roof of the beam and slab type, carrying about three feet of earth for protection from frost.

The Filters.—Coagulated and settled water is conveyed into the filter house by a concrete flume with connections to each of the 15 units. The top of this flume forms the floor of the operating gallery, and below it is the pipe gallery. Each filter unit has an area of 696 square feet, and is divided into two equal parts by a central gutter of concrete to which are connected eight lateral gutters of cast iron, four on each side. The filtering material consists of 9 inches of gravel graded in size from ⅛ inch to ¾ inch, upon which rests 27 inches of sand having an effective size between 0.4 mm. and 0.65 mm. and a uniformity coefficient ranging from 1.5 to 1.8. The rate of filtration at which the plant is operating and for which it was designed is 1.67 gallons per minute per square foot of filtering area. The strainer system is the New York Continental Jewell Company's standard type, consisting of an elliptical cast iron header with a section equal in area to an 8-inch pipe and manifolds of 1¾-inch lateral pipe spaced on six-inch centres. These laterals are drilled and tapped on their top



View Showing Orifice Boxes.

sides at intervals of six inches to receive the strainers. The elliptical header pipes are also drilled and tapped for a double row of strainers. This arrangement provides four strainers for each square foot of filtering area. The strainer heads are mounted on ⅝ inch tubes extending into the lateral pipe to form a water seal and effect a proper distribution of air while washing. Each strainer contains thirty-three one-sixteenth-inch holes. The system, when assembled in place, is embedded in concrete so as to leave only the upper portions of the headers and strainer caps exposed.



View of Filter Gallery of the Filtration Plant.

The wash water main is 30 inches in diameter with 16-inch branch connections to each filter. The water is supplied under pressure from the storage tank, passing up through the bottom of each header of the strainer system, out through the laterals and up into the filtering material. The main air line is 12 inches in diameter with 8-inch connections to each filter.

The piping is carried above the wash water gutters and is connected at two points in each header by a 4-inch vertical pipe. The filtered effluent passes into the clear water basin through rate controllers of the Venturi type and 14-inch down-draft tubes, one for each unit. The valves for controlling all the connections to and from the filter units are hydraulically operated, double gatevalves and are controlled from an operating table, one of which is provided for each unit. The pistons of the valves are operated by water under pressure from the company's distribution system.

Telescopic Storage Tank.—The distinctive feature of this plant is the large telescopic storage tank for the supply of wash water and air under pressure for washing the filter beds. This tank is built in two sections; the upper one telescoping into the lower one after the manner of a gas holder.

For washing one filter unit, water must be delivered at the rate of 5,000 gallons per minute for about three minutes, and pumping capacity to this extent would be necessary if no storage were provided. This would require a motor-driven pump operating at 125 h.p. for short periods, and would permit of the washing of only one unit at a time. With the storage capacity provided in the tank a pump of small capacity operated continuously by a 15 h.p. motor is sufficient.

Further, two filter units may be washed simultaneously without affecting the power consumption. As the power for operating the plant is purchased at a flat rate based on the peak load, the great economy of this arrangement is abvious. The conditions governing the supply of air for agitating the beds are precisely the same, a 5 h.p. motor and blower being sufficient as against 60 h.p. required without the intervention of storage. There is the further advantage that the air and water are supplied under more nearly uniform conditions than would be possible by direct supply from pumps or blowers. In order to compensate for varying levels of water in the tank, an automatic pressure regulator is provided at the outlet. The air is maintained at a constant pressure by the loading of the top of the inverted tank with a slab of concrete about three feet in thickness.

The small pumps and blowers supplying the tank are automatically controlled by floats and require practically no attention from the operators.

Chemicals.—The chemical storage room and the appliances for mixing and preparing the sulphate of alumina and hypochlorite solutions are situated on the floor above the machinery room and the prepared solutions delivered by gravity to their points of application. The alum is dissolved in rectangular tanks with perforated bottoms open to the storage tanks below. The solution thus prepared is conducted through lead pipes to the suctions of the low lift pumps, an arrangement which ensures a thorough mixing of the alum with the raw water.

The hypochlorite is fed to the mixing tanks through grinders which deliver the material in a finely divided state, ensuring a thorough mix.

Both alum and hypochlorite are provided with motor driven agitators to maintain a uniform density of the solution.

The flow of these solutions is regulated by means of orifice boxes, in which a constant level is maintained and from which the solution is fed through graduated orifices of hard rubber.

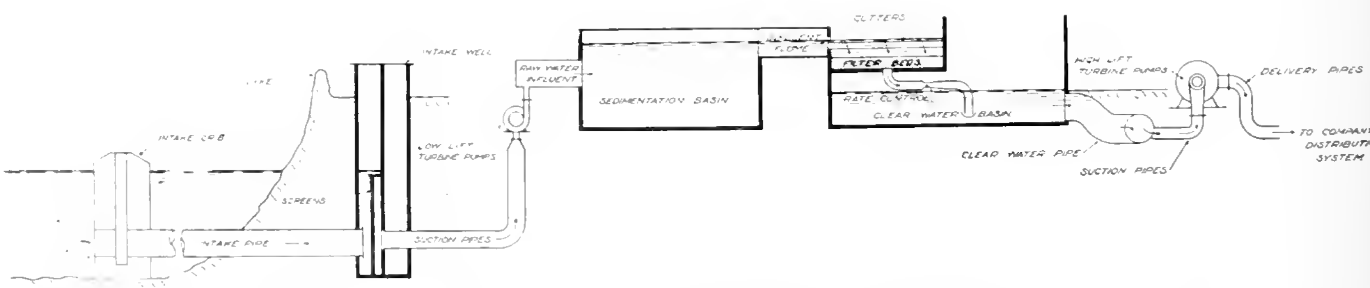


Diagram Showing Course of Water Through Filtration Plant, Montreal Water and Power Company.

The plant has now been in successful operation for about six months and is delivering clear, colorless and practically sterile water.

The plant was designed and constructed for the Montreal Water and Power Company, under the supervision of Mr. F.

H. Pitcher, general manager and chief engineer, and Mr. Wm. H. Sutherland, assistant engineer of the company.

The contractors were Messrs. Laurin and Leitch, of Montreal, and the entire mechanical equipment, detailed plans, etc., were furnished by the New York Continental Jewell Filtration Company, as sub-contractors.

The mechanical operation of the plant is in charge of Mr. W. G. Dryden, superintendent, and the sanitary engineer is Mr. J. O. Meadows, formerly sanitary engineer of the Provincial Board of Health, Quebec.

STEAM BOILER EXPLOSIONS.*

By William H. Boehm.

Every year there occur in the United States between 1,300 and 1,400 serious boiler accidents, of which 300 to 400 are violent explosions. These accidents kill between 400 and 500 persons, injure 700 to 800 more, and destroy more than a half million dollars worth of property. These disasters have but scant respect for boiler types for they occur with water-tube boilers, although with them violent explosions occur less frequently than with fire-tube boilers. They also occur with low-pressure boilers.

It is of the utmost importance that boilers be carefully designed, that the stresses to which they are subjected be accurately computed, that suitable material be specified, that the material be critically examined for flaws or defects, that specimens of the material be tested to determine its strength, that no abuse of the material be allowed in the process of constructing the boiler, and that the completed boiler be subjected to a thorough inspection and a hydrostatic test before being put into service.

The stress in the girth seams of a boiler may be obtained by the formula

$$S = \frac{r\,p}{2\,t}$$

in which

S = Stress per square inch to which the material is subjected;
r = Radius of the boiler;
p = Steam pressure carried;
t = Thickness of the shell.

The formula means that if we multiply the shell radius by the steam pressure, and divide the product by twice the shell thickness, the result will be the stress in pounds per square inch to which the material in the girth seams is subjected.

The stress in a side seam of a boiler may be obtained by the formula

$$S = \frac{r\,p}{t}$$

which means that if we multiply the shell radius by the steam pressure and then divide the product by the shell thickness, the result will be the stress in pounds per square inch to which the material in a side seam is subjected.

An inspection of these formulas show that the stress in a side seam is just twice as great as the stress in a girth seam. It is for this reason that the side seams are usually double riveted when the girth seams are only single riveted.

The pressure required to rupture the shell of a cylindrical boiler is given by the formula

$$P = \frac{s\,t}{r}\,e$$

in which

P = Bursting pressure in pounds per square inch;
s = Tensile strength of the material in the boiler;
r = Radius of the shell;
e = Efficiency of the riveted side seam.

Stated in words the formula means that if we multiply together the tensile strength of the material, the thickness of the shell, and the efficiency of the riveted side seams, and then divide the product so obtained by the radius of the shell the result will be the steam pressure at which explosion will occur.

If it so happens that the efficiency of the girth seam is too low by reason of improper design, then the girth seam may fail instead of the side seam, in which case the bursting pressure is given by the formula

$$P = \frac{2\,t\,s}{r}\,e'$$

which means that if we multiply together twice the thickness of the shell, the tensile strength of the material, and the efficiency (e') of the girth seam, the result will be the steam pressure at which explosion will occur. The girth seam is not likely to fail before the side seam, because to do so the efficiency of the girth seam would have to be less than half that of the side seam a weakness that should not exist in a boiler of proper design and construction.

The formulas expressed herein give the pressure at which the boiler will explode and not the pressure at which it may be safely operated. It is usual in boiler practice to fix the allowable working pressure for a new boiler at one-fifth the computed bursting pressure and to decrease the pressure allowance as the age of the boiler increases.

This is equivalent to saying that the factor of safety applied to a new boiler is usually not less than five. The term "factor of safety," is often misunderstood and a better name would be "factor of ignorance," as it is as much a factor of ignorance as it is a factor of safety.

Take, for example, the case of a new boiler operated with the safety valve set at 100 lb. If the computed bursting pressure be 500 lb., then the assumed factor of safety is five. The assumption, however, is based upon the tensile strength stamped in the plate by the maker and this strength is only true of that particular part of the plate from which the test specimen was cut and not necessarily of any other part.

As a matter of fact it is current practice to cut the test specimen from the outer edge of the plate and the strength there is almost invariably greater than the strength at the centre of the plate. The reason is that after liquid steel is poured into a mold its solidification in forming an ingot proceeds in much the same manner as does the solidification of water in forming a block of ice. That is to say, the impurities and gases are driven toward the centre.

Boiler plates made by the rolling of such an ingot will, therefore, have more impurities and less strength at the centre of the plate than at the outer edges, and this variation in strength is very considerable. Then, too, the stress at which the elastic limit of the material is reached is little more than half the stress at which rupture occurs.

Besides our ignorance of the dependable strength in all parts of the plate, there is also our ignorance of the character of the workmanship in the boiler. We cannot be certain that all rivet holes come fair, or that incipient cracks

* Abstract of a lecture delivered at Cornell University before the state branch of the American Society of Mechanical Engineers.

have not been set up by an abuse of the material during the process of construction. It is seen, therefore, that factors of safety are really made up of two parts—one part a true factor of safety, the other a pure factor of ignorance.

Boiler explosions may be attributed to improper installation, or incompetent or careless operation.

Improper construction may consist: of unsuitable or inferior material; poor workmanship; abuse of material, as when unmatched rivet holes are drift-pinned to place, or uncylindrical shells are sledged to form; of employing the more dangerous lap joint for the side seams instead of the more safe and more sensible butt joint, etc.

The lap joint is dangerous because this form of construction promotes the formation of incipient cracks in the upper surface of the lower lap where they may be impossible of detection. These cracks extend from rivet hole to rivet hole and gradually deepen with the continued raising and lowering of the steam pressure until the metal, no longer capable of resistance, gives way and causes a violent explosion.

The lap joint is given the preference over the butt joint solely, because, it appears at first thought to be cheaper. But there is no excuse for its existence, and its employment in the construction of new boilers should be prohibited by law in all states, as it now is in some.

Improper installation may consist of so supporting the boiler and its piping as to allow temperature changes to set up dangerous stresses in the material, of improperly attaching the usual appurtenances such as safety valves, steam and water gauges, check, blowoff, stop valves, etc.

Incompetent or careless operation may consist in allowing the steam gauge to get out of order, in allowing the water-gauge connections to become so clogged as to indicate ample water when there is none in the boiler, in allowing the safety valve to become so stuck to its seat as to fail to blow at the pressure for which it was set, in allowing grease to enter or scale to accumulate in the boiler, in allowing large quantities of cold water to be impinged against hot plates, in allowing the water to be driven from the heated surfaces by forced firing, in allowing a large valve to be opened too suddenly, in allowing two boilers to be cut in on the same steam main when their pressures are unequal, and in allowing minor repairs to be neglected until they endanger the whole structure.

It is significant that many violent boiler explosions occur either just prior to the starting of the engines in the morning or while they are idle at the noon hour, or shortly after they have been shut down for the day. One reason is that when steam is not being drawn from the boiler it accumulates rapidly; and if the safety valve fails to relieve the pressure, explosion soon follows.

The rapidity with which the bursting pressure is reached may be shown as follows:

Let

T = Time in minutes required to reach the bursting pressure;

W = Weight of water in the boiler;

t = Temperature of the steam at bursting pressure;

t' = Temperature of the steam at normal working pressure;

U = Number of heat units per minute supplied by the furnace and absorbed by the water.

The heat balance is then represented by the equation:

$$UT = W\,(t - t')$$

$$T = \frac{W}{U}\,(t - t')$$

which means that if we multiply the difference between the temperature of the steam at bursting pressure and at normal pressure by the weight of the water in the boiler, and then divide the product by the number of heat units supplied per minute by the furnace, the result will be the number of minutes that will elapse from the time the openings are all closed until explosion follows.

Take, for example, a 100-h.p. boiler containing at normal level 5,000 lb. of water and suppose it uses 50,000 heat units per minute when evaporating 50 lb. of water per minute. Then if the normal gauge pressure be 85 lb., the corresponding temperature of the steam is 327 deg., and if the bursting gauge pressure be 485 lb., the corresponding temperature of the steam is 467 deg.; and the time required to reach the bursting pressure with all steam openings closed and the safety valve stuck is:

$$T = \frac{5{,}000}{50{,}000}\,(467 - 327) = 14 \text{ min.}$$

That is, with a stuck safety valve, only 14 minutes would elapse from the time the engines were shut down until the explosion followed.

The temperature of the water in a boiler is approximately the same as the temperature of the steam with which it is in contact. If the fire be drawn when the openings are closed, ebullition ceases. If a valve be opened, ebullition starts again, even though there still be no fire under the boiler.

It is plain, therefore, that with the openings closed it is the pressure on the surface of the water that prevents further generation of steam. It is also plain that if a small rupture below the water line a violent explosion may not ensue. But it ought to be evident that if a large outlet above the water line be suddenly opened, as, for example, when a steam pipe fails, then the sudden liberation of the pressure on the surface of the high-temperature water will allow it to flash suddenly into steam and cause a violent explosion and water-hammer that will disrupt the strongest possible construction.

Grease does not dissolve or decompose in water, nor does it remain on the surface. Heat in the water and its violent ebullition causes the grease to form in sticky drops which adhere to and varnish the metal surfaces of the boiler. This varnish by preventing the water from coming into intimate contact with the metal, prevents the water from absorbing the heat, and this causes a blistering or burning of the plate that often results in a serious rupture, or a violent explosion.

If scale is allowed to accumulate to any considerable thickness in a boiler, a bag or rupture of the shell is inevitable, unless the scale happens to be of a spongy formation, which is not often the case. Just why this is so, is shown by the following simple experiment.

Take an ordinary granite iron or tinned iron stewpan and firmly glue to its underside a postage stamp. Pour water into the pan and place it on a gas stove so that the postage stamp will be in direct contact with the flame. Leave the pan on the stove until the water has boiled violently and then examine the stamp. The stamp will not even be charred, much less burned, notwithstanding that it was on the underside of the pan and in direct contact with the hottest part of the flame.

Now put into the pan a mixture of water and Portland cement half an inch thick. This, when set, will be the equivalent of half an inch of scale. Repeat the experiment made before and it will be found that the stamp will burn up very quickly.

The reason that the postage stamp is not charred by the flame when no scale is present is that the water, being in immediate contact with the thin bottom of the vessel, absorbs the heat as fast as it is put into the vessel by the flame. The result is that, no matter how hot the flame may be, the bottom of the vessel remains at practically the same tem-

perature as the boiling water with which it is in contact. In an open vessel the temperature of boiling water is 212 deg. and this is not sufficiently high to char paper. When scale is present, the water cannot absorb the heat as fast as it is put into the vessel by the flame, and as a result the temperature becomes greater than 212 deg. and burns the postage stamp.

It is the same with steam boilers. If the water comes in direct contact with the thin plates, the heat is absorbed, the temperature of the plates remains practically the same as the water, and no harm is done. If there be a considerable thickness of impervious scale in the boiler, the water cannot absorb the heat as fast as it is put into the plates by the furnace, and so the plates become overheated, get red, become plastic, and finally give way to the force of steam pressure, causing a bag, or a rupture, or a violent explosion of the boiler.

Scale endangers the safety of boilers in other ways. It clogs the feed pipes, preventing the feed water from freely entering the boiler. It clogs the connections to the water gauge, causing it to indicate ample water when it is at a low level in the boiler. Pieces get under valves and prevent their closure.

Scale in boilers is a serious matter, and in order to prevent its accumulation, it is good practice to eliminate the scale-forming matter from the feed water before allowing it to enter the boiler. This can be accomplished either mechanically by means of separators, or chemically by treating the water in vats especially arranged for the purpose. If preferred, compound may be fed with the water into the boiler, but in such case the water should be analyzed, and the proper compound prescribed by a chemist making a specialty of such matters. Kerosene fed into the boiler has proved beneficial in many instances.

It is an almost universal custom for boiler owners to have their boilers insured and inspected. The insurance serves as a guarantee that the inspections will be intelligently and carefully made and the inspections lessen the chance of accident.

When boiler insurance is carried, an inspector visits the plant at regular intervals and critically examines the boilers, both internally and externally. During the past 10 years the company represented by Mr. Boehm made 1,101,140 examinations and reported 140,989 defects, many of which consisted of dangerous fractures in or near the riveted seams, and that one boiler out of every eight examined, contained defects serious enough to warrant their being reported.

CLEANING THE WATER MAINS.

It is of interest to note that during the past five years the water department of Cincinnati had been been almost constantly employed in removing deposits from the water mains of that city. Previous to 1907 the muddy Ohio River water, having a turbidity varying from 7 parts per million to over 300 parts per million, was pumped directly into the distribution system. In 1907 the purification plant was installed and placed in operation. The deposits in the mains so decreased their capacity as to make it necessary to remove them, and although the work has been in progress for five years a large part of the system still remains to be cleaned. The enormity of the expense of cleaning will be recognized from the cost figures which vary from 10 cents to 26 cents per foot of pipe cleaned. The carrying capacity of the distribution system is greatly increased after the deposits are removed and an increased pressure results at all points on the distribution system.

DRIVING THE LARAMIE-POUDRE TUNNEL.

General methods and records of progress in driving the Laramie-Poudre Tunnel were described in our issue of April 10, 1912. The bonus system used in paying the men and descriptions of the method of loading the holes is of special interest and are further described in a paper by David W. Brunton, published in a recent Bulletin of the American Institute of Mining Engineers. We abstract from this paper as follows:

European tunneling methods were copied as closely as the American wage scale and differences of conditions would permit. A workman once assigned to a position in the tunnel remained there, not being allowed to change even from one side to the other. He was not allowed to drop his tools at shift-change, but was obliged to hand them to his successor, and, in case of his successor's non-arrival, was expected to work another shift, care being taken, of course, that either a substitute was found, or meals were sent in to the man working a double turn.

To give each man a personal interest in the work a bonus system was maintained. At first the bonus paid to each underground workman was 25 cents per day for each 25 ft. in excess of 400 ft. for the month.

After a few months this schedule was discontinued, as it was found to be both cumbersome and excessively high, considering the rate of progress made possible by the superior equipment; and the following bonus rate was adopted:

When the rate of driving for any calendar month exceeded 400 ft. and was less than 500 ft., each underground employee was paid $10 extra; between 500 and 600 ft., the bonus was $15; and between 600 and 700 ft., $20.

This bonus should have been paid to the men in currency, so as to distinguish it from the earnings under the wage schedule, but, as this was impracticable, money earned under the bonus was paid with a separate check, thus giving the men a better opportunity to realize what speed meant to them as well as to the contractor.

The list of employees and their rate of wages is as follows:

1 Superintendent		$ 10.00	per day
3 Foremen	each	5.00	per day
9 Drillers	each	4.50	per day
6 Helpers	each	4.00	per day
18 Muckers	each	3.50	per day
6 Drivers	each	4.50	per day
3 Dumpers	each	3.50	per day
1 Track and pipeman		3.50	per day
1 Master mechanic		6.00	per day
1 Stable boss and janitor		3.00	per day
2 Power engineers	each	110.00	per mo.
1 Car greaser		3.00	per day
1 Man at odd jobs		3.00	per day
1 Timberman		4.00	per day
1 Timberman's helper		3.50	per day
2 Blacksmiths	each	5.00	per day
2 Blacksmith's helpers	each	3.50	per day
1 Book and timekeeper		110.00	per mo.

In the operations of setting up the machines, drilling, firing and mucking, the utmost regularity and system were observed; and, while the time consumed in these different operations varied somewhat from day to day, there was a remarkable degree of uniformity in the amount of work performed by the different shifts.

Picking down the roof and squaring up places on the sides for the drill-bar rarely occupied more than 10 minutes. The adjustable end of the cross-bar was always placed on

the right-hand side of the tunnel, the lifter on this corner having been exploded last for the purpose of clearing away the muck and leaving plenty of room for the men to operate jack-bars. The drillers and the foreman attended to this work while the helpers were busy bringing forward the hose, air-pipe, water-pipe and steel. Even with the tremendously heavy charges fired, most of the broken rock lay within 30 ft. of the face and rarely exceeded 5 ft. in depth at any point, making it easy to bring the bar and drills over the muck pile.

The fuses were always ignited and the charges fired in rotation.

The usual practice of tamping the holes over the explosive was soon discontinued, as it was found that with such heavy charges the powder formed its own tamping, with the further advantage that when the holes were loaded to the collar the rock was more thoroughly pulverized and consequently much easier shoveled into the cars than when lighter charges were used.

Holes will occasionally miss fire, even when loaded with the greatest care; and when no tamping is employed they can be afterwards fired by simply pushing a primer down tightly upon the unexploded charge, without taking the risk of performing that most dangerous of all operations, picking the tamping out of a "missed" hole.

At first, each pair of fuses was lighted about ten seconds before the next—which, on 40-second fuse, gave 3-in. steps on the receding line of fire. This interval, however, being repeated on 10 pairs of holes, occupied considerable time, and the smoke became so intolerable that some method of expediting the rate of fuse-lighting had to be adopted. The one which proved most satisfactory was exceedingly simple. The foreman cut 22 ins. from the ends of the fuse protruding from the short cut holes; 20 ins. off the fuse from the upper cut holes; 18 ins. off the fuse in the lower cut holes, and so on. This automatically provided a difference of 2 ins. in the distance the fire had to travel, and, even when the fuse-ends were lighted as rapidly as possible, at least another inch was represented by the time between the lightings, so that the two shot-firers could secure the necessary interval between the explosions, and yet get away from the face before the smoke from the burning fuse became too dense.

The following tabular recapitulation of the drilling-operations shows that the men could not only complete a round in an 8-hour shift, but had sufficient extra time to provide for shooting missed holes or taking care of any of the minor difficulties which often arise in tunnel work.

Time Occupied in Various Operations.

Exhausting smoke from face	10 to 12 min.
Picking down roof and sides	5 to 10 min.
Jacking cross bar in place	6 to 8 min.
Attaching drills, making hose and water connections	5 to 15 min.
Drilling from top set-up	3 hr. to 4 hr. 15 min.
Dropping horizontal bar to lower position	15 to 20 min.
Drilling on lower set-up	1 hr. to 1 hr. 15 min.
Removing drills, cross bar, hose, etc.	15 to 20 min.
Blowing out holes, loading and firing	20 to 25 min.
Ignition to explosion of last hole	8 to 8 min.
Total time required to complete cycle of operations	5 hr. 24 min. to 7 hr. 28 min.

During March, April and May, 1911, the record months for driving, the following data were gathered, showing the amounts of work done:

	March.	April.	May.
Ft. of tunnel driven	653	583	635
Number of holes drilled	1,965	1,759	1,985
Linear ft. of holes	14,330	12,510	15,263
Ave. lin. ft. of holes daily	154	139	164
Sticks of powder used	14,808	16,171	18,311
Cars (16 cu. ft.) of muck sent out	4,983	4,765	5,156

Considering the hardness of the rock, the speed attained in drilling, as shown by the figures above, was exceptionally good; but even these averages fall considerably below what was possible with the equipment used. For instance, a number of the best drill-runners were able to average over 60 ft. of holes per shift, one of them making a monthly shift average of 61.68 ft.; another of 61.75 ft.; and a third of 61.86 ft.

While this work shows a great advance over current American practice, it still falls behind the records obtained in the best examples of European tunnel driving. A direct comparison, however, is not quite fair to the United States, since the Alpine tunnels are very much longer than anything yet attempted in this country. At first sight, it would seem that additional length would tend to retard instead of accelerate the rate of progress; but this is not the case. It has been clearly shown that the increased length of transportation and difficulty of ventilation are much more than offset by the improved conditions and the perfection of organization effected by time and experience. As a rule, the greater the magnitude of the undertaking the more thorough the preparation; and the time and labor expended in studying conditions and designing plants for the different Alpine tunnels have been more than justified by the results obtained. European tunnel engineers have also the advantage of being able to select their employees from an almost unlimited supply of highly-skilled workmen from the Tyrol, Switzerland and Piedmont, which gives them an incomparably better selection than can be drawn from our heterogeneous labor supply.

ILLINOIS WATER SUPPLY ASSOCIATION.

The fifth annual meeting of the association will be held at the University of Illinois, Champaign-Urbana, Illinois, March 11 and 12, 1913.

Titles of papers to be presented at the meeting should be sent to the secretary before February 20, 1913. A number of good papers have been promised, but we have room on the programme for more. Prepare a short paper, 1,000 to 1,500 words, on some topic that has been interesting you and that may help someone else. Send to the secretary items that are troubling you. The programme committee can arrange to have a discussion on the subject.

Associates intending to exhibit, please notify Mr. G. C. Habermeyer, Engineering Hall, University of Illinois. The usual arrangements have been made for the exhibits. If the exhibits are sent in care of Mr. Habermeyer they will be delivered at the University.

In the hydraulic laboratory there will be an exhibit of apparatus illustrating the principles of washing filters. In the water survey laboratory there will be an exhibit of water softening by permutit and water sterilization by ultraviolet light.

The University band will give an informal concert for the association. A subscription dinner will be held Tuesday evening, March 11. In order that suitable arrangements may be made, sign and return the enclosed card to the secretary at once. Programmes showing railway lines and hotel accommodations will be mailed February 24 to members and to others who return the card. Edward Bartow, secretary.

COAST TO COAST.

Steveston, B.C.—The cost of engineering ventures, road and sidewalk extension, during 1912 was $70,000, and is divided up into the wards as follows: Ward I., $7,595.23; Ward II., $7,605; Ward III., $10,705; Ward IV., $11,062.50; Ward V., $23,193.65.

Fort William, Ont.—The first two car loads of structural steel to be used in the construction of the plant of the Canada Car and Foundry Company, arrived in this city recently, consigned to the Dominion Bridge Company. There will be 3,000 tons of metal in the buildings of the Car Company's plant here.

Prince Albert, Sask.—The new council of this city decided to erect a market building, appoint a parks board to take charge of the Prince Albert annual exhibition, to push forward as quickly as possible the erection of an isolation hospital, and to take immediate steps towards the erection of an incinerator.

Regina, Sask.—A material reduction in the cost of power to the citizens of Regina has been recommended owing to the large surplus of $70,000 having been obtained by the power plant last year. It is the intention of the officials to charge a rate that will only be sufficient to pay the cost of producing power and provide a slight surplus each year.

Halifax, N.S.—The plans providing terminal facilities that will make Halifax the best equipped port on the continent, while it will enjoy the advantage of being the nearest of all the ports to Europe, were discussed by Senator Wm. Dennis, who is on his way to Ottawa. It is understood that the development and equipment that is to provide for Halifax's present needs and its wants in the immediate future will involve an expenditure of at least $20,000,000.

Moose Jaw, Sask.—Evincing the progressive tendencies of Western Canadian municipalities, Leonard W. Rundlett, former St. Paul city engineer, now city commissioner of Moose Jaw, cites the fact that this city is installing a high pressure system of fire protection. The method is used in but few cities of the United States. Winnipeg, Toronto and Moose Jaw are the only Canadian cities with high pressure systems. As a starter for the work $600,000 has been appropriated.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.

The annual meeting of the American Institute of Consulting Engineers was held January 14, 1913, at the Engineers' Club, New York City.

Mr. Henry Holgate, of Montreal, Canada; Mr. Daniel E. Moran, of New York City, and Mr. Charles Sooysmith, of New York City, were elected members of council to serve three years, and Mr. F. A. Molitor, of New York City, was elected a member of council to serve one year.

After the routine business of the meeting was transacted, Prof. George F. Swain, of Harvard, addressed the meeting on the question of "Education," which was very ably discussed by Mr. Rudolph Hering, General T. A. Bingham, Prof. Gardner S. Williams, of Ann Arbor, Michigan, and Mr. Frank J. Sprague. Mr. Eugene W. Stern is the secretary.

Mr. Noulan Cauchon, A.M.Can.Soc.C.E., addressed the members of the Ottawa Branch of the Canadian Society of Civil Engineers and their friends on Thursday, December 16th. He chose as his subject "Town Planning and Beautification," illustrating his various statements with lantern projections depicting work of this nature in Europe.

TORONTO UNIVERSITY ENGINEERING SOCIETY MEETING.

On Tuesday, January 21st, Mr. Frederick W. Taylor addressed the Engineering Society of the Faculty of Applied Science and Engineering of the University of Toronto on "Scientific Management." The meeting was held in Convocation Hall, about 700 being present.

"Any scheme that makes for increased efficiency cannot be stopped. History shows this time and again," was the keynote of Mr. Taylor's address. Mr. Taylor illustrated this by referring to the many futile strikes that have taken place on the introduction of means to increase efficiency. The attitude of the workman in "soldiering" was a result of a mistaken attitude of financial men in not paying sufficiently for increased output. "The workman is no fool. He soon learns how little he can do for the money," he said. It was the overcoming of this attitude in employer and employee that was the main problem in introducing scientific management.

PERSONAL.

J. McD. PATTON, superintendent of waterworks, of Regina, Sask., has tendered his resignation to the city commissioners.

CLIFFORD RICHARDSON, M.Am.Soc.C.E., consulting engineer, New York City, on January 17th delivered a lecture on "The Economics of Highway Construction," before the graduate students in Highway Engineering at Columbia University.

C. L. FELLOWES has resigned his position of deputy city engineer of Toronto, which he has held since 1898. Mr. Fellowes, in all probability, will remain with the Works Department and will take charge of the plans for the new mains and services in the Waterworks Department.

F. A. CREIGHTON, of Prince Albert, Sask., who recently resigned his position in that place as city engineer, has been offered the position of manager of construction of La Colle Falls civic electric development project. He will also be retained as consulting engineer in any engineering problem that may arise.

GEORGE POWELL, B.A.Sc., has succeeded Mr. C. L. Fellowes as deputy engineer of the city of Toronto. The former post held by Mr. Powell of principal assistant engineer is abolished. Mr. Powell is a graduate of the School of Practical Science in Civil Engineering. During 1903-4 he was employed with the Canadian Niagara Power Company at Niagara Falls, Ont., on the work incidental to the installation of their new plant. In the fall of 1904 he came to Toronto to act as engineer for a firm of contractors. Mr. Powell entered the service of the city in 1906, and has been with them continuously to date.

ANTHONY D. MacTIER, who was appointed as general manager of the Eastern lines of the Canadian Pacific, with headquarters at Montreal, Que., recently, was born on December 27, 1867, at Blairgowrie House, Scotland, and was educated at Sedbergh school, Yorkshire, England. He began railway work in May, 1887, in the general baggage agent's office of the Canadian Pacific, and was later in the general superintendent's department. He was then in the department of the superintendent of sleeping, dining and parlor car stores, and later in the car service department. In April, 1896, he was appointed general baggage agent, and in November, 1890, became general fuel agent. He was appointed assistant to the vice-president of the Canadian Pacific in June, 1907, and now becomes general manager of the Eastern lines of the same road.

ANNUAL MEETING OF ONTARIO GOOD ROADS ASSOCIATION.

The annual meeting of the Ontario Good Roads Association has been announced for February 26th, 27th and 28th, and the programme now in course of preparation will be issued shortly. Road construction and maintenance, concrete and steel bridges, and the building of town streets, will be discussed. Honorable J. O. Reaume, Minister of Public Works, will deliver an address. L. W. Page, Director of the United States Office of Public Roads at Washington, will attend and address the convention on "Road Maintenance." The city engineer of Toronto, Mr. G. G. Powell, will contribute a paper on "Town and City Streets." Other addresses will be delivered by the mayor of Toronto, the president of the Toronto Board of Trade, and Mr. W. A. McLean, chief engineer of highways for Ontario, who will discuss county road organization and construction.

COMING MEETINGS.

ILLINOIS WATER SUPPLY ASSOCIATION.—The Fifth Annual Meeting of the Association will be held at the University of Illinois, Campaign-Urbana, Ill., March 11th and 12th, 1913. Secretary, Edward Bartow.

AMERICAN WOOD PRESERVERS' ASSOCIATION.—Ninth Annual Convention will be held at Chicago Jan. 21-23, 1913. Secy-Treasurer, F. J. Angier, Mount Royal Station, B. & O. R. R., Baltimore, Md.

ENGINEERS' CLUB OF TORONTO.—Meeting of the Members will be held on Friday evening, January 24th, at 8 p.m., in the Lecture Room, 96 King Street West, Toronto. Secretary, R. B. Wolsey.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual Meeting will be held on Jan. 28th, 29th, and 30th, 1913, at the Society's new headquarters, 176 Mansfield St., Montreal. Secretary, C. H. McLeod.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright Secretary, Mr. Hugh B. Fergusson, 911 Rogers Building, Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre: Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr, G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—P e ident, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

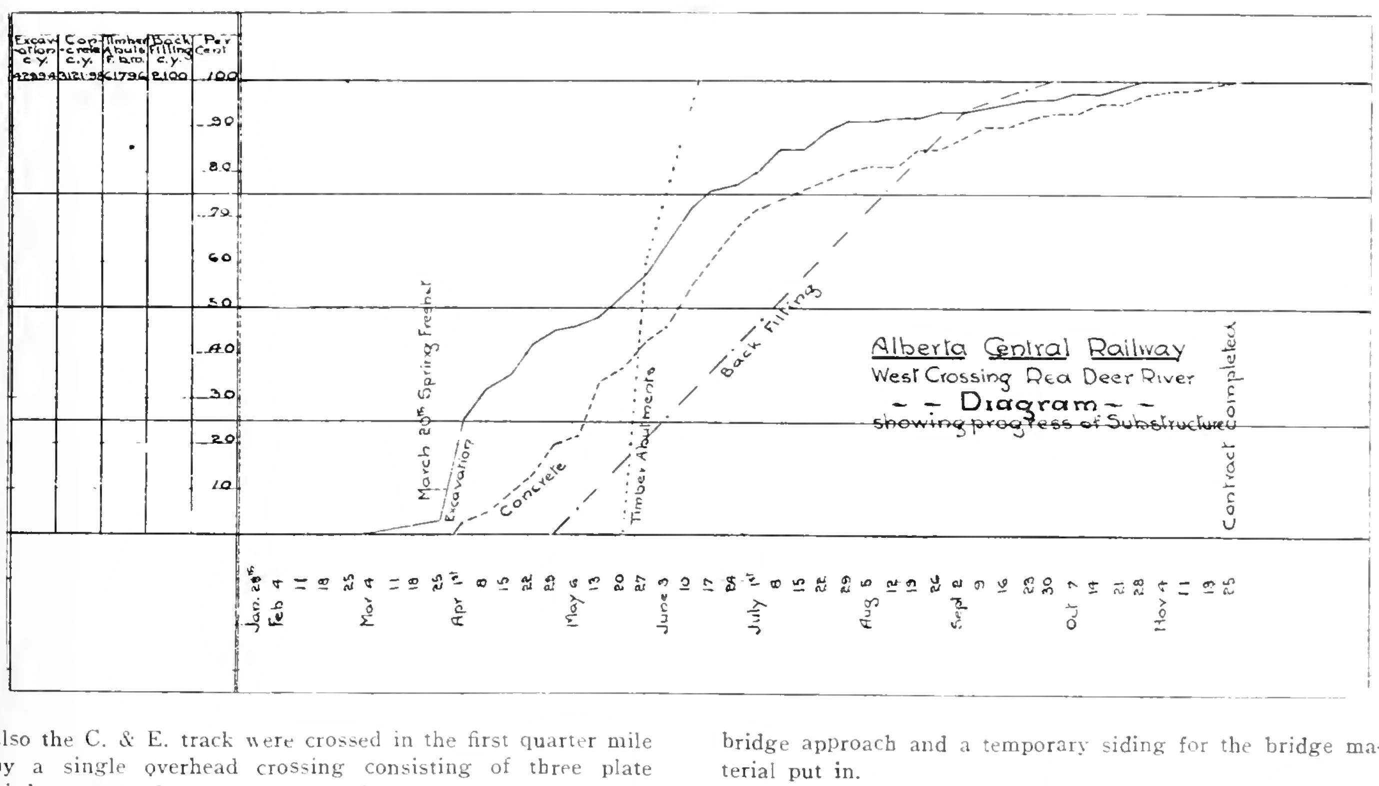
An Engineering Weekly

THE RED DEER RIVER BRIDGE—ALBERTA CENTRAL RAILWAY

By HUGH A. LUMSDEN, B.Sc.

The Alberta Central Railway obtained its charter from the Dominion Government in 1909. The line was projected both east and west from Red Deer, a growing town of about 2,500 population, midway between Calgary and Edmonton on the C. & E. branch of the Canadian Pacific Railway. Mr. J. Grant MacGregor was appointed chief engineer and location surveys were made during the winter of 1909-10.

Construction was commenced by the company in the summer of 1910, the first spike being driven by Sir Wilfrid Laurier in August of that year. The Waskasoo Creek and



also the C. & E. track were crossed in the first quarter mile by a single overhead crossing consisting of three plate girder spans, the centre one resting on concrete pedestals 25 feet above the C. & E. track, and the ends resting on wooden abutments. No other engineering difficulties were met with until mile 5.5, where the banks of the Red Deer River were encountered, and it is with the crossing of this valley that this article is chiefly concerned.

Many preliminary surveys for the bridge were made, and after months of careful study of the ground, the present and best possible location for the bridge was decided upon.

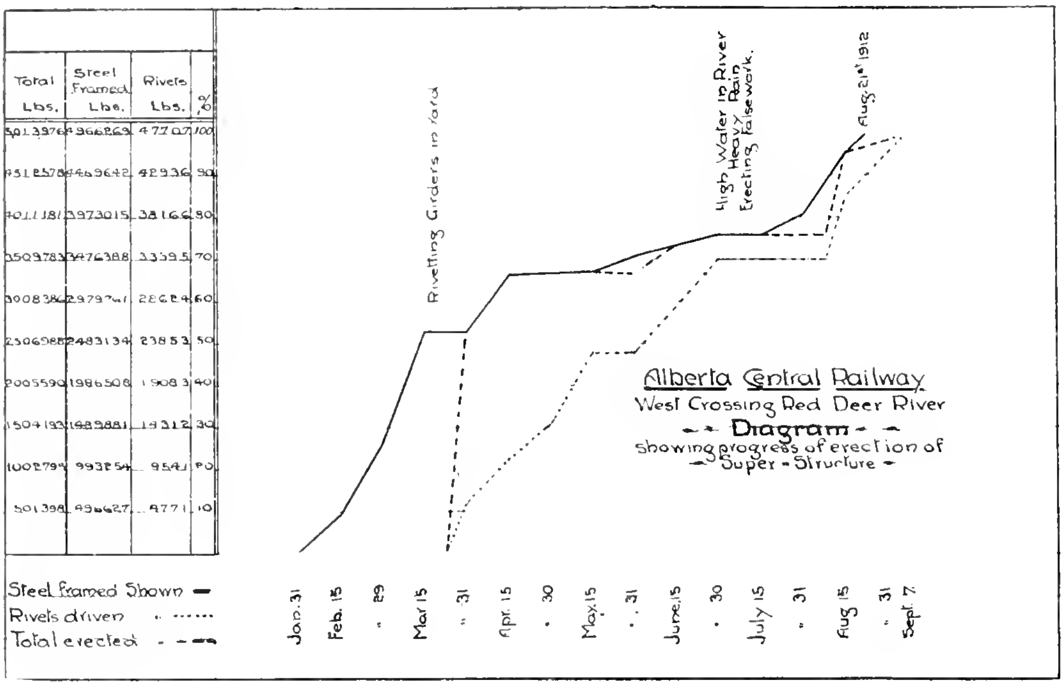
The Red Deer River itself is only about 300 feet wide, and averages about 5 feet deep with a mean discharge of about 2,200 cubic feet per second, but both the height and discharge vary very greatly with the season of the year. The valley through which it flows, is fairly wide, and in very few places only are the banks less than half a mile apart. The ground is a clayey loam with a layer of rock underlying the river bed. The east bank slopes gradually and reaches the flat 90 feet below in about 1,200 feet, falling slightly thereafter to the river's edge; the west bank is steeper, rising from the river bed 135 feet in a distance of 1,000 feet.

In the fall of 1911 track was laid from Red Deer to the bridge approach and a temporary siding for the bridge material put in.

The bridge is approached from the east on a 2 degree curve ending about 700 feet back of the abutment. The alignment is a tangent throughout and the gradient a 0.4 per cent. rising westward. The total length of the bridge is 2,172 feet 6 inches from end to end of the abutments. Three hundred feet west of the bridge a long 5 degree curve commences and the line swings northwards.

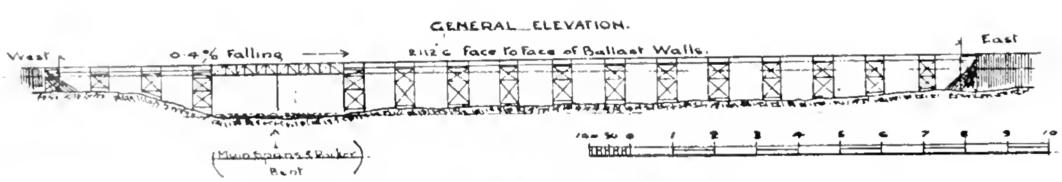
The wooden abutments at either end of the bridge were built by the Alberta Central, the pile driving being commenced about the end of March, 1911, and the abutments completed early in June.

The embankment at the end of the east abutment is about fifty-five feet high and that at the west about forty feet; the approaches were graded by sub-contractors under D. F. McArthur and Company. Some trouble was later experienced, due the sinking and shoving forward of these abutments caused by the shrinking and pressure of the embankments, but it is the intention in due time to replace the present structures by those of concrete.



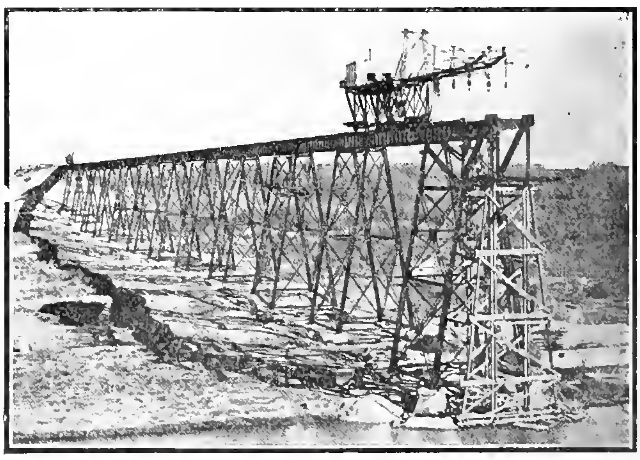
The original design for this bridge was prepared by the chief engineer in 1909 and submitted in 1910 to Mr. P. B. Motley, consulting bridge engineer for the Alberta Central and Canadian Pacific Railways, who made certain changes and modifications and introduced a rocker bent. The design thus decided upon, with the exception of the main truss spans, the rocker bent and the deck floor, was very similar to that of the Lethbridge viaduct, built by the Canadian Pacific Railway in 1907-08. It consists of fifteen deck plate girder spans each 74 feet 10 inches long and fifteen similar girder spans each 45 feet long, carried on 30 rigidly braced steel towers, the distance centre to centre being 45 feet, and of adjacent towers 75 feet. The river itself was spanned by two rivetted deck truss spans of the Warren type, each 150 feet long, supported by towers at one end of each and at the centre by a single pair of legs about 80 feet long forming a rocker bent. This rocker bent is perhaps the most unusual feature of the whole bridge, and is a form of construction which has not been very widely used in bridge building in Canada hitherto; in such a case as this, however, replacing, as it does, a very high and expensive concrete pier it makes a very serviceable and neat member.

The contract for the substructure of the bridge, consisting of 56 pedestals, 4 piers, two on either side of the river and a large centre pier in the middle of the river, and containing in all about 3,122 cubic yards of concrete, was awarded Messrs. Jackson and Goldie, of Winnipeg. Excavation was commenced by them on March 1st, 1911, and the last pier completed on November 21st.



General Elevation of Bridge.

The contract for the superstructure was awarded the Canadian Bridge Company, of Walkerville, Ont., who commenced erection on the last day of January, 1912, having previously erected their traveller and assembled much of their material on a siding just east of the bridge site. Erection proceeded very rapidly and towards the end of April tower 24 (numbered from east to west) was reached, and the erection of falsework for the first main span across the river commenced. Here the first and only accident occurred, a man being instantly killed by falling about 40 feet while erecting falsework. Considerable delay was now experienced, due the excessively heavy rain which fell the greater part of July and not only prevented work, but raised the river to such an extent that even the erection of falsework had to be discontinued for nearly three weeks. A few bents which were being used as a temporary platform were carried down the river and recovered near Red Deer. In the meantime rivetting up of back work was proceeded with by "four guns," steam being obtained from an engine in a shed close to the river bank, where also the bridge camp was situated. The falsework, consisting of six bents resting on piling, is well illustrated in one of the accompanying photographs.



Progress of Erection, Middle of May, 1912, Looking East.

The rocker bent and second main span were completed by the middle of August, and on August 21st, 1912, the last girder was lowered into place, and after two weeks more spent in rivetting and paint-

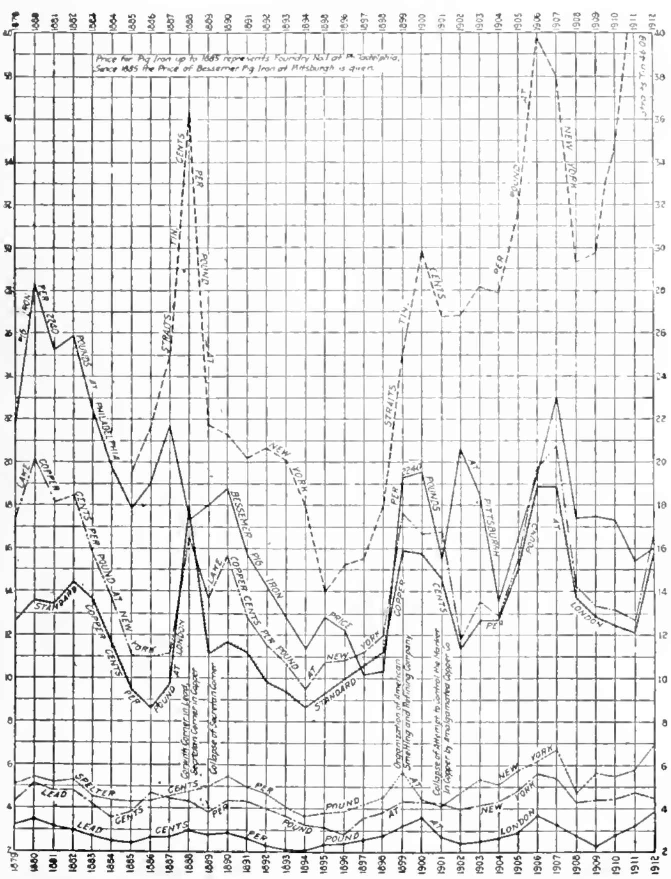
ing the bridge was completed. The total weight of steel placed in the bridge was 3,013,976 pounds.

The work was under the direct supervision of Mr. MacGregor, assisted by a resident engineer at the bridge. Mr. R. Turner was C.P.R. bridge inspector on the work and Mr. T. Frankish superintendent of construction for the Canadian Bridge Company.

View Showing Lateral Bracing of Main Truss Spans.

View of the Completed Pier No. 26.

Accompanying are several photographs of the work taken during erection; also diagrams showing the progress of erection both of the substructure and superstructure.



Course of Metal Prices Since 1879—Annual Averages as Compiled by the Engineering and Mining Journal.

CANADIAN RAILWAYS AND ROLLING STOCK IN 1912.

The year 1912 was a period of great activity in railroad car construction as well as rail extension and a resumè of the car and locomotive orders issued by the directorate of the various Canadian roads during the past twelve months makes an interesting item.

The following are the orders of the Canadian Pacific Railway:—

Box cars	24,141
Flat cars	1,370
Stone cars	400
Ballast cars	616
Stock cars	865
Refrigerator cars	522
Horse cars	38
Dump cars	20
Tank cars	20
Automobile cars	100
General service cars	411
	28,403

The passenger car orders are composed of:—

Sleeping cars	106
Dining cars	25
Tourist cars	57
Baggage and express cars	76
First-class cars	117
Compartment sleeping cars	3
Buffet parlor cars	8
Colonist cars	2
Second-class cars	12
Mail and express cars	13
Baggage and smoker	1
Horse express cars	2
Fruit express cars	1
Baggage cars	50
	473

The locomotive orders of this company for the period mentioned consist of 493 machines of the superheater type in sizes ranging from 19 x 24 to 23½ x 32 inches.

The Canadian Northern have placed some large orders for rolling stock during the past year, their freight car orders being composed of the following:—

Box cars	3,600
Automobile cars	100
Flat cars	1,050
Caboose cars	50
Tank cars	10
Refrigerator cars	100
Stock cars	150
Construction cars	324
	5,384

Passenger cars ordered by this company indicate increased business, and comprise the following:—

First-class cars	30
Café-parlor	2
Baggage	15
Baggage and mail	9
Dining cars	2
Sleeping cars	16
Second-class	25
Self propelled	1
	100

The locomotive orders are for 104 superheater machines varying from 24 x 32 to 19 x 26. When the car orders of the Canadian Northern Railway are considered it is necessary to enumerate the orders of the Canadian Northern Ontario and the Canadian Northern Quebec Railways, both of which are connected with the Canadian Northern Railway. The freight car orders of the Canadian Northern consist of:—

Box cars	200
Coal cars	50
Construction cars	76
	326

Passenger car orders:—

First-class cars	12
Second-class cars	3
Café-parlor cars	2
Baggage cars	4
Dining cars	2
	23

Locomotives ordered number ten of the superheater type 22 x 26 inches. The freight car orders of the Canadian Northern Quebec Railroad are made up thus:—

Box cars	300
Flat cars	50
Coal cars	50
Caboose cars	20
	420

Passenger car orders:—

First-class	3
Second-class	12
Excursion cars	6
Café-parlor cars	2
Baggage cars	2
Baggage and mail cars	2
Self-propelled	1
	28

The management of this railway also ordered 8 locomotives of the superheater type; 6 were 22 x 26 and 2 were 19 x 26.

The freight car orders of the Grand Trunk indicate that that railway is rapidly forging to the front and consist of:—

Box cars	2,000
Refrigerator cars	500
Automobile cars	500
Flat cars	300
Tank cars	50
	3,350

The passenger car orders of this line are made up as follows:—

Sleeping cars	15
Second-class	10
Colonist	15
Tourist	5
Dining	6
Café-parlor	6
First-class	10
	67

The locomotive orders of the Grand Trunk Railway are for 100 machines in sizes ranging from 20 x 26 to 27 x 30 inches; 85 of these machines are of the superheater type. In addition to the locomotive orders of the Grand Trunk Railway it appears that 40 machines were ordered for use on the lines of the Grand Trunk Pacific; these machines are 23 x 30 and 33 x 30 inches.

The Intercolonial Railway officials have placed some large orders for rolling stock during the past year; their freight car orders tabulating as follows:—

Box cars	1,643
Construction cars	200
Flat cars	200
Refrigerator cars	30
Tank cars	1
Stock cars	20
Caboose cars	10
	2,104

The passenger car orders of these lines include:—

Sleeping cars	4
Dining cars	2
First-class cars	7
Baggage cars	3
	16

The locomotive orders of the Intercolonial number 28 machines in sizes varying from 20 x 26 to 24 x 32. Twenty of these machines are of the superheater type.

The Prince Edward Island Railway must be considered as next in order to the Intercolonial; the freight car orders of this line being for 15 construction cars and 1 tank car. There is no record of passenger car or locomotive orders for this line during 1912.

A small line that has done considerable ordering is known as the Paris and Mount Pleasant Railway. This line have placed orders for 12 box cars, 3 first-class passenger cars, and 1 combination car, in addition to one locomotive of the superheater pattern 18 x 24 inches.

The freight car orders of the Toronto, Hamilton and Buffalo Railway are for:—

Freight cars	1,250
Flat cars	10
Construction cars	254
	1,514

There is no record of any passenger car orders for this line for the past year, but 4 locomotives were ordered of the superheater type; two being 23 x 28 and two 21 x 28 inches.

The Temiskiming and Northern Ontario Railway ordered four box cars.

The Quebec Central ordered 100 rack cars and 6 locomotives.

The Algoma Central and Hudson Bay Railroad ordered 70 general service cars, 4 first-class passenger cars and 5 locomotives of the superheater type, each 22 x 28 inches.

The Algoma Eastern orders tabulate as follows:—

Box cars	25
Flat cars	24
Construction cars	70
	119

Passenger cars:—

First-class cars	2
Second-class cars	1
Passenger and baggage	2
	5

Locomotives ordered by this line were two in number, both of the superheater type.

The Sydney and Louisburg Railway ordered 75 hopper cars and 2 locomotives.

Although the steam roads have placed heavy orders, they are not the only large purchasers of rolling stock, as the following orders for electric cars will show.

The Berlin Street Railway Company purchases 1 open car.

The Berlin and Waterloo Street Railway purchases 2 semi-convertible cars.

The British Columbia Electric Railway purchased:—

Closed cars	109
Freight cars	115
Semi-convertible	35
Snow sweepers	2
Electric locomotives	5
Dump cars	6
Baggage and express cars	4
	276

The management of the Calgary Street Railway have placed the following orders:—

Closed cars	30
Trailer, passenger	1
Snow sweeper	1
Sprinkler	1
Sight-seeing car	1
	34

The Edmonton Street Railway Company or the Edmonton Radial Railway, ordered:—

Semi-convertible cars	50
Work car	1
Dump car	1
	52

The Guelph Radial Railway Company ordered 2 snow sweepers.

The Halifax Electric Tramway Company ordered 4 closed cars and 1 snow sweeper.

The International Electric Railway Company (Niagara District) ordered:—

Closed cars	326
Snow sweepers	4
	330

The Lethbridge Municipal Tramway Company ordered 10 closed cars.

The London and Lake Shore Railway and Transportation Company ordered 4 closed cars and 1 baggage car.

The Montreal and Southern Counties Railway Company ordered 6 closed cars and 2 combination cars.

The Montreal Tramway Company ordered:—

Closed cars	75
Snow plow	1
Snow sweepers	2
Crane car	1
	79

The Oshawa Electric Railway Company ordered:—

Convertible cars	2
Express car	1
Snow sweeper	1
Electric locomotive	1
	5

The Ottawa Electric Railway Company ordered 10 closed cars.

The Quebec Railway, Light and Power Company ordered 2 snow sweepers.

The St. Thomas Street Railway Company ordered 2 closed cars.

The City of Toronto Municipal Lines ordered 8 closed cars and 2 snow sweepers.

The York Radial Railway Company ordered 4 semi-convertible cars.

The Saskatoon Municipal Street Railway ordered 12 closed cars.

The Regina Municipal Street Railway Company ordered 30 closed cars.

The Nipissing Central Railway ordered 2 closed cars.

The Sandwich, Windsor and Amherstburg Railway ordered 2 closed cars.

The total number of cars and locomotives ordered during the year 1912 is 44,303.

The increase of electric railway mileage in Canada during the same period is shown below:—

Berlin & Northern Railway Co.—Through Bridgeport	0.25
Calgary Municipal Railway	18.50
Edmonton Radial Railway	2.50
Guelph Radial Railway Co.	0.60
Halifax Electric Tramway Co., Limited	0.75
Lethbridge Municipal Tramway	11.00
Levis County Railway.—Between St. Romaud and Gorman's Bridge	1.50
London Street Railway Co.	1.00
Moncton Tramways Electric & Gas Co., Limited	2.25
Montreal & Southern Counties Railway Co.—Between St. Lamberts and Greenfield Park	3.00
Montreal Tramways Co.—Montreal	2.07
Nipissing Central Railway.—Between Cobalt, Haileybury and New Liskeard	5.70
Oshawa Railway Co.—Oshawa	2.00
Regina Municipal Railway	3.50
St. Thomas Street Railway	0.50
Sandwich, Windsor & Amherstburg Railway.—In Windsor and Sandwich West	1.25
Saskatoon Municipal Street Railway	22.00

MONTREAL AND SHAWINIGAN POWER RIGHTS.

An announcement of much interest to shareholders of the Montreal Light, Heat and Power and the Shawinigan Water and Power Companies is likely to be made soon in connection with the rights which are likely to accrue to them through the offering of the new issues of the Cedar Rapids Manufacturing and Power Company. A special meeting of the directors of the two companies first mentioned has been held to canvass the situation and the final details of the issue have been decided. Circulars will shortly be sent to the shareholders of the two concerns advising them of the offering of $8,000,000 of new bonds of the Cedar Rapids Company and the terms upon which the offering will be made. The price may be 90 per cent. of par, a bonus of 25 per cent. of common stock to accompany the bonds. The shareholders of the two companies will likely have the privilege of subscribing in the ratio of 30 per cent. of their holdings of Power or Shawinigan.

It is about a year since the interests in control of the two concerns came to the conclusion that they required the Cedar Rapids power for their future operations and reached an understanding with Mr. D. Lorne McGibbon for the purchase of a controlling interest. The Montreal Light, Heat and Power Company is the distributing agent in Montreal for the power it develops in its own plants as well as that developed by Shawinigan. It will also distribute for Cedar Rapids.

A RETAIL COAL HANDLING PLANT ON THE PACIFIC COAST.

From time to time articles have appeared in the technical press dealing with the getting of coal. It is proposed here to discuss its handling after leaving the mine and before it reaches the consumer.

The coal here considered is mined at South Wellington, Vancouver Island. It is a semi-bituminous coal and very friable. An analysis of a sample of screenings from this coal follows:—

	%
Moisture	2.0
Volatile combustible matter	35.10
Fixed carbon	43.6
Ash	18.5
Sulphur	0.8
	100.0

The coal is mined by means of coal cutting machines whilst the use of powder is being discontinued.

After arrival at the surface the coal is screened and picked, the screenings going to an independent screening and washing plant. The lump coal only as thus screened is dealt with in this article. The lump coal is delivered into railway cars straight from the screens, whence it travels seven or eight miles to the coast, where it is discharged from a trestle through chutes on to a belt conveyer, which carries it direct to a scow, passing over a weighing machine on the way.

Owing to the range of the tide (which is about 12 ft.); at low tide the depth from end of conveyer to deck of scow is about 20 ft. These two drops break up the coal considerably as the trestle is set high enough to take the screenings through the washing plant. The scows are towed about 55 miles to Vancouver, the re-handling plant being located on False Creek, right in the heart of the city.

The requirements of the trade demand that lump coal be free from slack and delivered in 100 lb. sacks.

The method originally employed was to wheel by barrow from scow to pile in shed. It was then screened, sacked and weighed as required.

Now the scow is brought up and made fast at end of wharf as shown in plan, the adjustable slip is lowered on to side boards of scow and the peak of the coal (coal is heaped on the scow from 10 to 12 ft. deep) taken off. The slip is then lowered to deck of scow end boards removed, and the

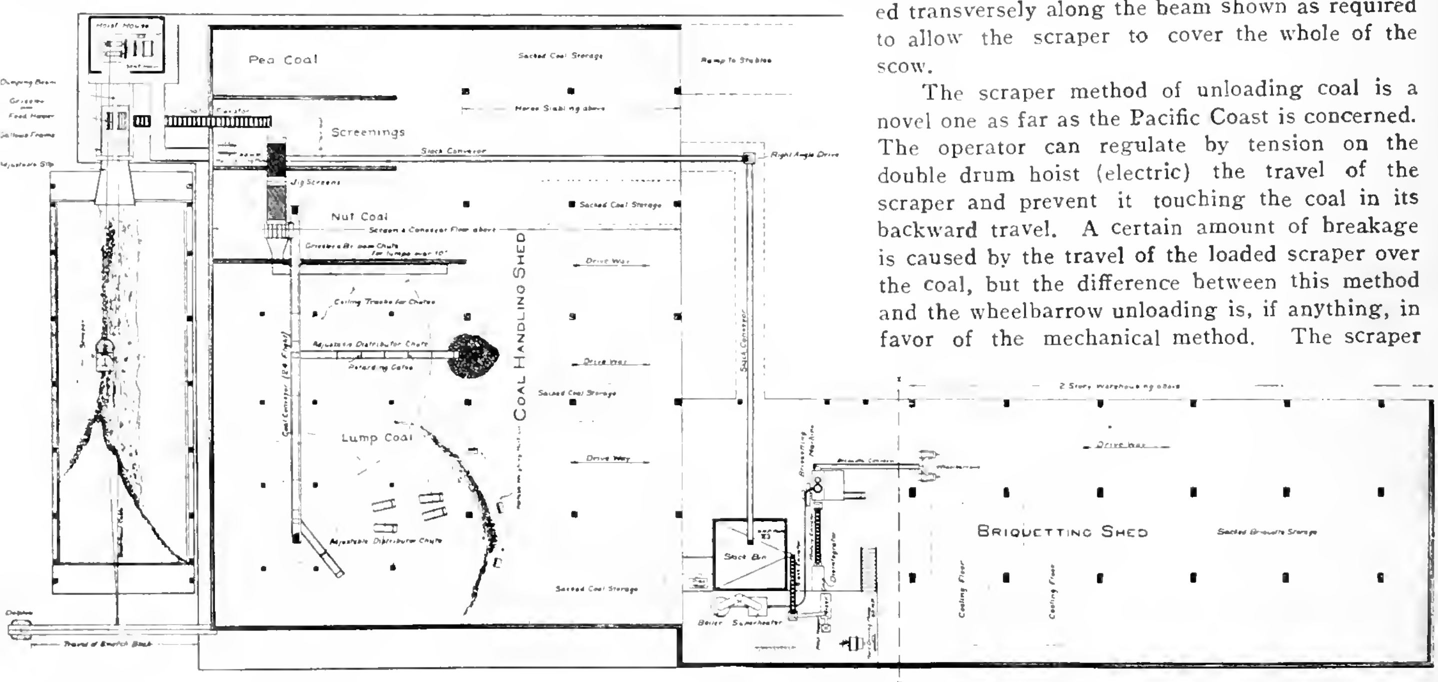
Slip for Unloading Coal on False Creek.

Vertical Heater Over Briquetting Plant.

remainder of the coal scraped off except a little in each corner near the slip. The scow is then turned end for end to permit of the remainder being removed. The operation can easily be followed from the plan, the snatch block being moved transversely along the beam shown as required to allow the scraper to cover the whole of the scow.

The scraper method of unloading coal is a novel one as far as the Pacific Coast is concerned. The operator can regulate by tension on the double drum hoist (electric) the travel of the scraper and prevent it touching the coal in its backward travel. A certain amount of breakage is caused by the travel of the loaded scraper over the coal, but the difference between this method and the wheelbarrow unloading is, if anything, in favor of the mechanical method. The scraper used is that patented by W. C. Weeks, and although designed for gravel handling, with minor alterations in the form of teeth, gives excellent resnlts with the coal. It is so arranged as to dump at the rear end by running the hauling cable over a snatch block located over the grizzly.

The unloading of coal by this method has proved very economical, whilst the first cost is considerably below the



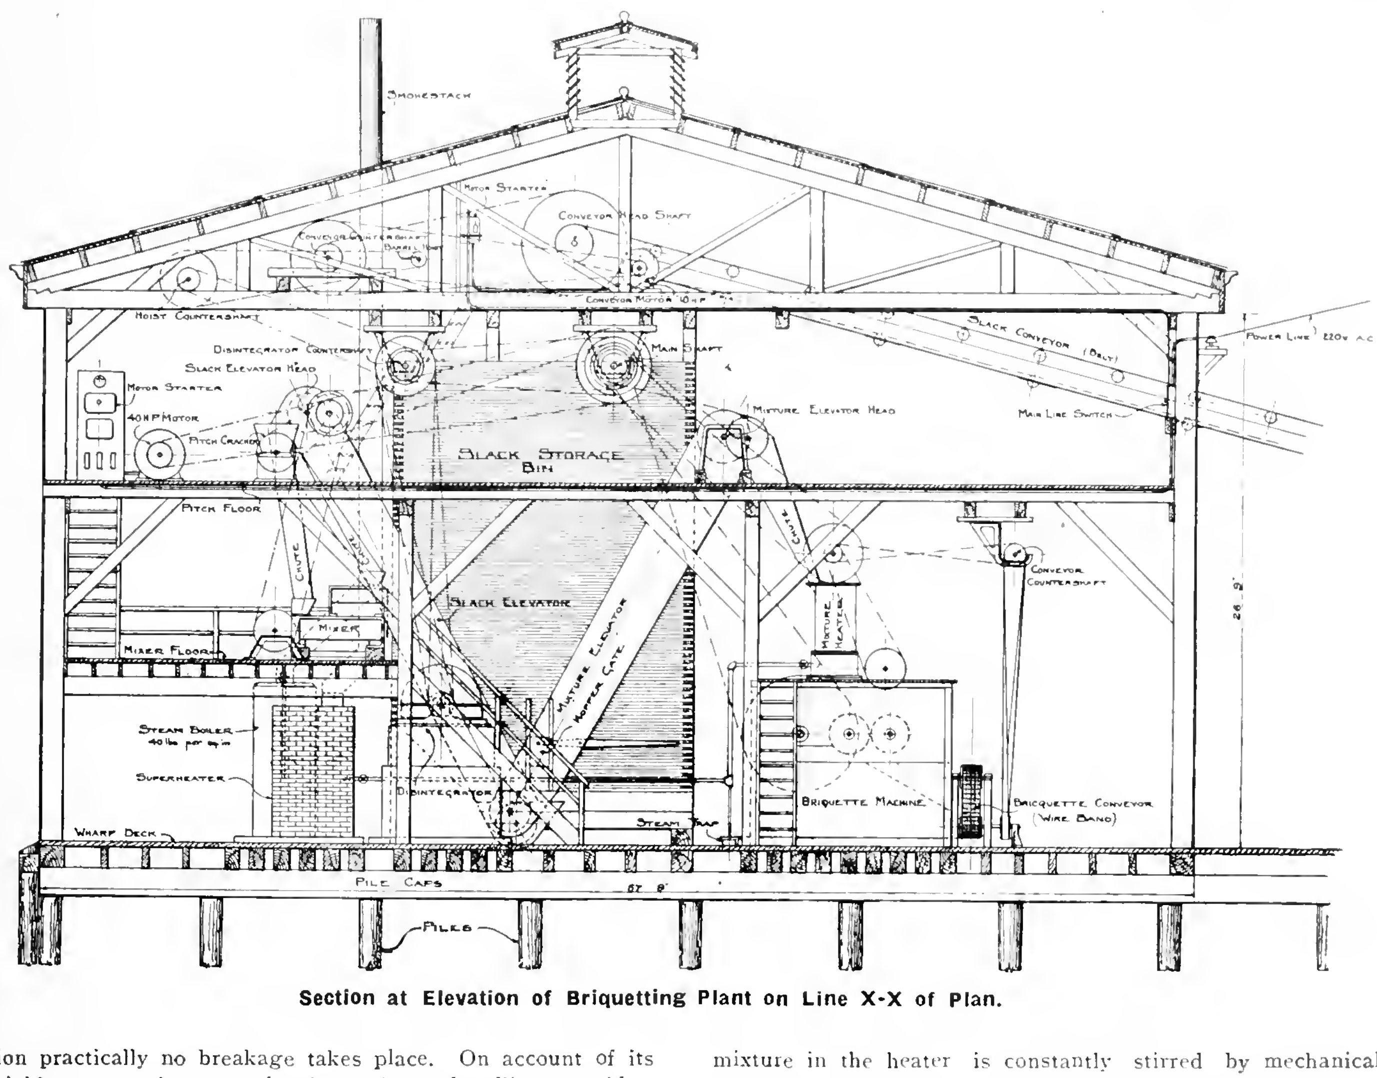
Diagrammatic Plan of Coal Handling Plant With Auxiliary Briquetting Plant on False Creek, Vancouver, B.C.

usual method adopted, viz., travelling derrick and clam shell bucket. A force of 12 men was formerly required to unload a 400 ton scow in 22½ hours. This is now accomplished by the scraper, with the assistance of two men, in 10 hours. From the receiving hopper the coal passes through a grizzly where everything over 18 ins. is retained until sledded down to that size. It is then conveyed by means of a bucket elevator to the jig screens which separate out the slack and nut into their respective chutes, whilst the lump passes forward on a flight conveyer to the adjustable distributor chutes. These chutes are hung from circular trackage from the ceiling so that they can be adjusted horizontally and and vertically. The coal is piled towards the front as shown in plan and as the pile increases the different sections of the chute are cast loose until such time as the coal piles back to the last section. These chutes are provided with retarding gates faced with rubber cushions to prevent breakage. When chutes are set at correct angle and retarding gates in operascreening, also now only half the number are employed sacking, the coal being taken direct from the pile on floor.

The slack chute discharges on to a 12-in. belt conveyer which takes it to a slack storage bin of 50 tons capacity in the briquetting shed. Here it is fed through a hopper as required to a bucket elevator.

The briquetting plant was manufactured by Yeadon and Sons, of Leeds, England, and is arranged as shown in plan and elevation.

The slack is conveyed by the bucket elevator to the mixer, whilst on the floor above the mixer is stored the pitch, and here is located the pitch cracker, so that the cracked pitch also falls into the mixer where it is fed on to the slack by an adjustable screw feed, regulated to give the correct percentage. From the mixer the product falls into the disintegrator. The mixture is then elevated into a vertical heater which is jacketed, and into which jacket steam, superheated to 360° F. at 40 lbs. pressure, is introduced. The



Section at Elevation of Briquetting Plant on Line X-X of Plan.

tion practically no breakage takes place. On account of its friable nature, however, in the entire re-handling considerable slack is formed subsequent to the first screening at the pit mouth, and this slack was formerly disposed of at greatly reduced value.

The percentage of slack on the scow runs (according to the stage of the tide at time scow is loaded) from 12 to 25% from tests made by careful hand screening, whilst after passing through the unloading and mechanical screening plant it is about the same, showing that the unloading and screening is not productive of furtner breakage.

The total number of men employed unloading and screening is three. Formerly the men sacking did the

mixture in the heater is constantly stirred by mechanical means so as to obtain a uniformly heated product and is then fed to the rolls of the press which turn out a briquette of an ovoid form weighing about 5½ ozs. each. These drop on to a wire band conveyer long enough to remove them clear of the plant, where they are received into wheelbarrows and spread over the cooling floors. Here they remain for 24 hours before being sacked. A small vertical boiler with separate bricked in superheater is used for supplying steam. The pitch used in the manufacture is coal tar pitch and amounts to 6% of the finished product for this particular coal. All the machinery is electrically driven by 220 volt three-phase induction motors.

A total of four men are required to run the briquetting plant. The briquettes find a ready sale at lump coal prices, whilst the demand is in excess of the output. They are giving every satisfaction both for furnace and range use.

The capacity of the plant is 45 tons per 10-hour run.

Head of Distributing Spout Showing Coal Feeding Into Same.

The coaling and briquetting plant here described is owned by the McDowell-Mowat Coal Co., Ltd., of Vancouver. Mr. Kerr, of the Canadian P. G. Mitchell Co., Montreal, superintended its construction. Mr. S. A. Lake, of Wilson and Lake, 422 Pacific Building, Vancouver, was the consulting engineer in charge of design and construction.

BRICKS FOR BUILDING AND FIREPROOFING

The total production of clay building brick, including the common and pressed varieties, and ornamental, paving firebrick, and fireproofing brick, is shown in the following statistics.

In 1911 the total sales were 732,901,056, valued at $6,515,472, made up of 645,550,517 common, valued at $5,420,890, or an average value per thousand of $8.37; and 87,350,539 pressed brick, valued at $1,094,582, or an average value per thousand of $12.53. In addition to the common and pressed brick there was a production of ornamental brick of 605,643, valued at $11,281, and a production of fireproofing brick and architectural terra-cotta valued at $409,585.

In 1910 the production was 627,715,319 common brick, valued at $5,105,354, or an average value per thousand of $8.13; and 67,895,034 pressed brick, valued at $807,294, or an average value per thousand of $11.89; the total of the two classes being 695,610,353, valued at $5,912,648. The production of ornamental brick in 1910 was 703,345, valued at $16,092; and of fireproofing and architectural terra-cotta, $176,979.

The increase in production of fireproofing has been particularly marked, and is due to the establishment of new plants, including the National Fire Proofing Company of Canada at Hamilton, Ont., and the Alberta Clay Products Company, Limited, of Medicine Hat, Alta.

The demand for brick has been very strong, particularly throughout the west, where numbers of plants are being increased in capacity and many new plants either contemplated or in course of construction.

The exports have never been large, averaging for a number of years past about $6,000 in value per annum, but falling in 1910 and 1911 to $2,762 and $3,977, respectively, according to the latest report of Mr. J. McLeish, B.A., chief of the division of mineral resources and statistics. The annual imports for a number of years previous to 1903 averaged only about $20,000 in value. During the past eight years, however, the imports have rapidly increased from $100,000 to nearly $500,000 per annum. During the calendar year 1911 the imports were 51,102,000 brick, valued at $475,865; of which 6,404,000, valued at $72,675, or an average of $11.35 per thousand, were imported from Great Britain; and 44,698,000, valued at $403,190, or an average of $9.02 per thousand, from the United States. The imports during the calendar year 1910 were 29,049,000 brick, valued at $274,482; of which 1,993,000, valued at $26,447, or an average of $13.27 per thousand, were imported from Great Britain; and 27,056,000, valued at $248,035, or an average of $9.45 per thousand, from the United States.

The total production of paving brick and paving blocks in Canada in 1911 was reported as 5,220,400, valued at $79,444, as compared with a production of 4,215,000, valued at $78,980 in 1910.

This paving brick is made at West Toronto, Ont., from shale obtained from the banks of the Humber River. The annual production has for a number of years varied from 3,000,000 to over 5,000,000 per season, and the output finds a market chiefly in Toronto. The average price per thousand has varied from $8 to $20.

The imports of paving brick have during the past three years exceeded the domestic production. During the calendar year 1911 the imports were 11,450 thousand, valued at $164,292, or $14.34 per thousand, and included 4,988 thousand, valued at $78,201, or $15.68 per thousand, from the United States, and 6,462 thousand, valued at $86,091, or $13.32 per thousand, from Great Britain. The imports during the calendar year 1910 were 10,503 thousand, valued at $124,994.

The manufacture of sand-lime or silica brick, although of comparatively recent origin in Canada, has developed with considerable rapidity during the past five years, for which statistics have been collected.

Returns received from sixteen producing firms showed total sales in 1911 of 51,535,243 brick, valued at $442,427, or an average of $8.58 per thousand, as compared with a production of 44,593,541 brick, valued at $371,857, or an average of $8.34 per thousand, by thirteen firms in 1910.

The total sales by nine firms in 1909 were 27,052,864 brick, valued at $201,650, or an average of $7.45 per thousand.

The number of men employed in 1911 was 337, and wages paid, $166,902.

RAILWAYS IN SASKATCHEWAN.

At the end of the season the Canadian Pacific Railway had 414.80 miles of main line and 1,659.45 miles of branch lines, or a total of 2,074.25 miles in Saskatchewan; the Canadian Northern Railway had 400.67 miles of main line and 1,653.93 miles of branch lines, or a total of 1,854.60 miles; and the Grand Trunk Pacific Railway had 415 miles of main line and 267.67 miles of branch lines, or a total of 682.67.

This gives a grand total for the province of 4,611.52 miles, made up of 1,230.47 miles of main lines and 3,381.05 miles of branch lines.

Throughout the whole season there was a shortage of labor, and much time was lost on account of the unsettled weather. When harvest time arrived the high wages offered by the farmers rendered it impossible to keep the construction gangs at full strength. The steel rail mills were slow in making deliveries, on account of the heavy demand for this material. These and other causes all contributed to delay construction, with the result that the number of miles of railway added during 1912 was much less than in other recent years.

AMERICAN WOOD PRESERVERS' ASSOCIATION.

Abstracts of papers delivered before the ninth annual meeting held in Chicago, January 21-22-23, 1913.

NATURAL AND ARTIFICIAL SEASONING OF DOUGLAS FIR FOR TREATMENT.

By Mr. F. D. Beal.

The above subject is one on which a large amount of knowledge is yet to be obtained.

Although we have been treating Douglas fir for about twenty-four years, we cannot say that we have yet developed a method of seasoning that could be considered wholly successful under all conditions.

In the first place, the wood being naturally hard and refractory in the seasoned state, sufficient penetration by pressure treatment alone could not be obtained to insure the full protection of the wood for a sufficient length of time to make the treatment a paying proposition. Therefore, it was decided very early in the history of the Pacific Coast treating, that some means of artificial seasoning would have to be resorted to in order to prepare the wood for the reception of the preservative used.

Our first move was to take up the steaming and vacuum process with which you are all more or less familiar; that is, of turning saturated steam directly on the timber and raising the temperature to a point to insure the thorough heating of the interior wood and vaporizing all sap moisture, etc., and the writer used to think they were vaporizing the wood itself by the looks of all the pitch, resin, etc., that used to come out through the drains.

This was carried on until the maximum vaporizing point was reached. A vacuum pump was then applied, heat being maintained in the cylinder by the circulation of superheated steam through steam heater pipes in the bottoms of the cylinders. This vacuum and superheated steam was carried on until the balance of the moisture, etc., was fully extracted from the cylinder. In this manner the wood would take the preservative under pressure very readily, but the strength of the material was so impaired as to practically condemn it for use in structures.

Various other schemes were then tried out with very little success until in 1894 Mr. John D. Isaacs conceived the idea of trying out a modification of the "Boulton Method" of seasoning by immersion of the unseasoned timber in creosote oil, using the oil as a medium for conveying the heat to the timber, raising the temperature of the oil above the boiling point of water—thus vaporizing the moisture in the wood, allowing it to pass off through vent pipes into condensers through which cold water was circulated, but eliminating the use of any vacuum pump.

In this manner, the timber was dried or seasoned with a lower degree of heat and left in good condition for the reception of the preservative under pressure.

This method of seasoning has been carried on continuously on the Pacific Coast now for over twenty years, and although there is some decrease in strength, the material is in much better shape and lasts longer than that air-seasoned or treated by steam.

At the present time experiments are being carried on at St. Helens, Oregon, at the St. Helens Creosoting Company's plant, on the seasoning of ten thousand Douglas fir ties. These experiments are being carried out under the direction of Mr. George E. Rex, of the Santa Fe Railway. The ties were selected and five thousand of them weighed. The ties that were weighed were tagged and numbered, record being taken of the same. They were then placed in the water during the months of May and June, 1912 They were cribbed in cribs of about sixty ties to the crib, but instead of being cross piled in the cribs they were all laid one way, separately, with one-inch strips nailed to the ties, the reason for this being that it was desired to place the ties in running fresh water with the ties lengthwise up and down the stream, thus allowing the water to pass through the entire length of the ties.

These ties were left in the water until about September 15th, when they were taken out and the five thousand reweighed to ascertain the amount of water absorbed. They were then piled in open piles to air season. When it is found that the ties are sufficiently dry they will be treated by pressure process alone, without any artificial seasoning.

The object of these experiments is to try and find some process of seasoning without the application of heat in order to retain the natural strength of the wood as much as possible, the theory being that, as with Douglas fir when sawed into lumber and immediately piled in the open air, the wood checks and splits excessively; also, when thoroughly air dried the wood becomes so hard that it is impossible to get any penetration with the preservative. Therefore, the idea of putting the ties in the water was to allow them to water season and wash out all of the saps and natural wood moisture; to then pile them in open piles, allowing the moisture that was absorbed during the immersion to evaporate. In this manner the wood would not check or split.

At the date of this writing, November 20th, 1912, the theory of eliminating the checking and splitting is working out admirably. The ties as yet show no evidence of splitting or checking in any manner.

One pile of the ties was selected to be weighed every fifteen days to determine the rate of seasoning.

It was at first intended that the ties should be treated in the creosoting cylinder about November 1st, but on account of the excessively heavy and continuous rain for the past month the seasoning has been retarded and it has now been decided to allow the treatment to go over until about February 1st, 1913.

At the time of the treatment of these ties there will be present engineers and representatives from a great many of the railway companies throughout the United States, and we herewith extend an invitation to all members of the association to be present at St. Helens, Oregon, at this time, as we expect to develop something new for the seasoning of Douglas fir.

LAYING WOOD BLOCK PAVEMENT.

By H. S. Loud.

A contract for wood block pavement usually includes regulating the entire portion of the street to be paved, removing the old pavement, regrading the street, readjusting other types of pavement at intersections, setting new curb, dressing and resetting old curb, resetting catch basins, manhole frames and sewer heads, putting in new concrete foundation and laying the wood blocks.

Before ordering the paving contractor to commence work the city should see that all sewer work, water and gas pipes, underground conduit, street railway tracks, etc., have been put in good repair.

The city should insist that all backfill over such trenches as are opened be thoroughly and properly tamped.

The first operation is to set the curb.

Then the old pavement is removed and the street graded from curb so that the subgrade shall be exactly parallel to the finished grade and as much below same as the added depth of the wood block, the cushion and the concrete foundation. Soft or spongy places should be dug out and refilled with proper material. Unless the subgrade is quite solid it should be compacted by tamping or rolling with a heavy roller.

Upon this subgrade must be placed a concrete base, finished with a commercially smooth surface, and from four to six inches in depth, depending on the traffic and the condition of the subgrade. The concrete should be constructed in accordance with the materials and methods described in the specifications reported by the committee on cement adopted January, 1912, by the Association for Standardizing Paving Specifications.

In general the question of concrete has been worked out in each locality according to the materials available, and all that is needed is a good substantial base that is deep enough to carry the traffic.

Great care should be taken to secure a smooth surface on the concrete and to keep it exactly parallel with the finished grade.

Three longitudinal rows of grade stakes should be put in. One row down the centre of the street and one row midway between the centre and each curb. The stakes in each row should be about fifteen feet apart. With a good concrete gang this should be sufficient, but with an inexperienced gang the stakes in each row should be closer. On a wide street intermediate rows should be added. For very particular work masons' lines may be stretched along the longitudinal stakes.

After the foundation has set thoroughly, a layer of sand, or of sand and cement (1 cement to 4 sand) is spread over it and struck to a true surface exactly parallel to the top of the finished pavement and as many inches below same as the depth of the blocks to be used. This cushion or bed is simply a means of securing a perfectly uniform surface for the blocks to rest upon, and if the concrete has been properly laid should not average over ½ inch in thickness for mortar cushion and one inch for sand cushion. Whichever material is used should be laid dry and free from pebbles. If it is not perfectly dry it should be combed out with a rake, smoothed to an approximate surface, rammed or rolled and then struck with a drawing board.

There are two ways of striking the even surface required. One of the most common, but not the best, is to use flexible strips of wood or iron about three-eighths of an inch thick and four inches wide. These strips are set parallel to each other and about eight or ten feet apart, running from curb to curb. They should be imbedded in sand throughout their length, so that their top surface shall be parallel to the grade of the finished pavement and as many inches below same as the depth of the blocks to be used. The space between the two strips having been filled with a bed material, a true and even top is struck by using an iron-shod straight-edge on the strips as a guide, and as soon as the bed has been struck the strip which would interfere with laying the block shall be removed and its place carefully filled in with cushion.

The other and better method is to draw the bed in a direction parallel to the curb. Instead of flexible strips pieces of wood are used about twelve feet long and as wide and thick as the blocks are deep. These guide pieces are set parallel to the curb and to each other and are bedded on cushion material throughout their length so that their top surface shall coincide with the top surface of the finished pavement. One such guide is placed next to each curb and one is set one foot off the centre of the street. The space between the guides having been filled with cushion material, a true and even top surface is struck by using an iron-shod templet which is one foot longer than one-half the street width. This surfaces one-half the bed. The middle guide is shifted one foot off centre in the opposite direction and the other half of the bed struck. The guides are then removed and the bed is ready for use without the necessity of any hand fluting. The templet has notched ends as it is drawn over guides which are level with the top of the finished pavement, while its drawing edge is below that level by the depth of the block. Shoes should be fastened to each end of the templet to prevent its tipping while being drawn.

The second method is much superior to the first. It is more accurate, quicker and cheaper.

The question as to whether a sand or mortar cushion should be used is a matter of opinion, as both have given excellent results. In general sand gives a true cushioning effect, and the blocks do not have to be rolled as soon after paving as when a mortar cushion is used. The mortar cushion is better on appreciable grades especially in car track work. If mortar cushion be used the pavement should be sprinkled sufficiently during the rolling of the block to supply water to set the concrete.

English and French practice does away with a soft cushion. The concrete base is floated over to a depth of one inch with a one to three mixture of cement and sand laid to the proper crown. This is allowed to set thoroughly.

After the bed is prepared provision for expansion joints is made by placing boards along each curb. These boards should be about six inches wide and thicker on one edge than the other, so that they may be easily withdrawn after the blocks are paved. They should leave an inch and one-half space to be filled with bituminous material.

Alongside the above board three rows of block should be paved parallel to the curb. On the rest of the street the block should be laid at right angles to the curb. Blocks should be laid neither too tight nor too loose—about so that before the joints are filled any block can be easily pulled out of the pavement by jabbing a knife blade into it.

The blocks should be paved with the grain vertical and all joints broken by a lap of at least three inches.

With streets of light traffic it is desirable and necessary to have transverse expansion joints. These should be about three-quarters of an inch wide and placed from 25 to 50 feet apart.

After the blocks are paved the surface should be rolled with a roller weighing from 2½ to 5 tons and then inspected, and any lack of uniformity or unevenness corrected by taking up and relaying the defective portion.

The joints should then be filled with clean sharp sand, perfectly dry and free from pebbles. The sand should be thoroughly broomed until the joints are completely filled. The surface should then be covered with one-half inch of sand and traffic admitted to the street. It will take about ten days under traffic for the joints to take up all the sand they require.

In England where they use a smooth hard concrete surface they lay two courses of hand-dipped (in pitch) block parallel to the curb. A space of from one to two inches is left between the curb and the wood block to allow for expansion; this space is filled with clean puddled clay or approved bituminous filler. After laying the blocks a mixture of boiling pitch and creosote oil is poured over the whole surface and well forced into the joints and the surplus scraped off with wooden or rubber squeegees. A top dressing of crushed stone, passing a ⅜-inch screen, is then spread over the pavement.

In some places the top of the concrete is flushed with a bituminous material just before paving.

It is desirable that wood block be paved into the street as soon after treatment as possible. For this reason it is well to have the concrete laid before the blocks are received and thus be able to deliver them directly to the pavers.

In case this is impossible, the blocks should be tight-piled along the line of the work and they should be protected from the sun by wet straw, tarred paper or similar means and sprinkled with water from time to time to keep them from drying out too much. In piling block alongside of the street it is desirable to make the piles as high as convenient, for they will occupy less sidewalk area and interfere less with pedestrian and delivery traffic.

In paving, care should be taken to keep the courses straight and at right angles to the curb. Special attention should be given to paving around manhole heads, street car tracks and other iron work. Blocks should be paved against a vertical surface; to get this it is necessary with rails and may be necessary with other iron work to plaster the abutting face with a rich mixture of sand and cement. It is absolutely necessary adjacent to all such iron work that the cushion be specially tamped and thickened so that the block when paved shall be from 3/16 to ¼ inch above the wearing surface of the iron. Traffic will bed these blocks down to the level of the iron in a short time.

Block paved as already outlined is all right for streets having a grade not over three per cent. Streets with greater grades should be paved with a ⅜-inch groove between each row of block. The best way of doing this is to separate each row with a creosoted strip ⅜ inch thick. The width of these strips should be one inch less in depth than the block, so as to leave a groove one inch deep. These grooves are sometimes filled with pebbles and pitch. Wood block should not be used on grades exceeding six per cent. except in special cases.

With wood block pavement the crown should be as light as possible; just sufficient to shed water freely.

Car-Track Work.—It has already been pointed out that in paving against street car rails the blocks should be set against a perpendicular surface and also paved about ¼-inch high. Between the car tracks it is possible to use this construction with a Trilby rail. With the old form of girder rail this may be done, too, but the surface of the block within the car tracks will be on a level with the wagon wheel tread of the rail.

A great many street railways use T head rail. Blocks may be paved against such rails by plastering the surface and paving low enough to allow the flange of the wheel to pass freely. This means that the pavement within the tracks will be about one inch below the abutting pavement. Or the rail may be plastered and the blocks paved from rail to rail at the same level as the surrounding pavement; the blocks that set up against the rail in this case must have one corner chanpfered off to permit the passage of the wheel flange. Instead of plastering the side of the rail, creosoted strips are often used. Specially formed blocks are also used.

Many bridges are paved with wood blocks Some of them have concrete roadways on which the blocks are paved substantially as outlined previously. Many have plank floors and some iron floors. Planks should be creosoted, surfaced to an even thickness and laid smooth. Blocks may be laid directly on the creosoted plank, but it is often desirable to cover the plank first with one or two layers of tarred paper. The joints between the blocks should be filled with bituminous filler. This filler is recommended for all bridge, shop and stable floors.

Whenever there is a plank foundation laid on a grade or with traffic all one way, it is desirable to fasten angle irons across the roadway every twenty feet or so to prevent the block from creeping.

In regard to the blocks themselves: they are made either three, three and one-half or four inches deep; their width varies from three to four inches, but all blocks in one improvement should be of the same width. Three-inch block should be limited in width between three and three and one-half inches. Deeper block should be four inches wide. The average weight per yard of wood block is 140 pounds for three inches deep; 165 pounds for three and one-half inches deep and 187 pounds for four inches deep.

As to treatment: twenty pounds per cubic foot of wood has been the standard in this country, but for heavily travelled streets 16 pounds is sufficient.

Long-leaf yellow pine and Southern black gum have been the standard woods for streets of heavy traffic. In the West they have also used Norway pine and tamarack, and in the East and South North Carolina pine is coming into great favor for residential streets, for those of moderate traffic and for streets with heavy grades. North Carolina pine more nearly resembles the creosoted wood used in Paris and London than does the long-leaf; it wears uniformly and permits crushed trap rock to be rolled into its surface, making it less slippery than long-leaf. It is ideal for state highways, where if used it should be laid with bituminous filled joints. It is also extensively used for factory floors.

In regard to the labor necessary to lay wood block pavement, leaving out the preliminary work of excavation, foundation, etc., I would say that an ordinary paving gang consists of a foreman, about four pavers, a bed-maker and his helper and some twelve laborers. The yardage that such a gang will lay in a day depends largely on local conditions, but they should pave in the neighborhood of five hundred yards per day on continuous work. The above men do not include those engaged in carting and piling the blocks on the sidewalk or the rolling.

THE TREATMENT AND CARE OF FLOORS.

By Geo. W. Saums.

In the very much larger demand for the preservation of cross ties, poles, and what might be termed wood for heavy duty, the application of preservative methods to wooden flooring has been neglected and has apparently received little or no attention at the hands of those who have been giving special and particular attention to the larger subject.

Everybody needs floors, and therefore as a matter of fact the care and preservation of floors is in reality also a large subject and worthy, it has always seemed to me, of more attention.

Wood used for flooring has no different characteristics from wood used for any other purpose, and is subject to precisely the same rotting conditions as when used for heavier work, and mainly, perhaps, because each individual floor in itself does not represent a very large outlay of money for maintenance, the fact that the aggregate of all floors does run into a large cost has been neglected, and unfortunately neglected to the extent that under present conditions concrete and other composition floors are rapidly being substituted for wood, especially where any heavy wear is likely, even though these compositions can never be as entirely satisfactory as a good wood floor, if that floor could only be preserved in good condition for a reasonable length of time.

Obviously, in addition to rot, it is necessary in floors to consider splintering and buckling, and it does not require a combination of any two or more of these difficulties to make it necessary to relay a floor. Upon the appearance of any one of them it means that sooner or later a new floor must be laid.

On account of these well-known troubles and the known properties of wood, in so far as their various properties are known, the use of wood for flooring has become more or less standardized—that is, maple for indoor floors where the wear is great and as long life as possible, with a good appearance, is required, irrespective of first cost. Oak, ash and chestnut in residences and ordinary offices, where there is no heavy traffic and pine for heavy traffic or where it may be necessary to offer more than usual resistance to dampness or other weather conditions. It would be impossible to cover the different variations in in the kind of wood used for floors according to individual whim or special conditions, for there are as many exceptions as there are rules on the subject, each of the the above kinds of wood, however, seeming to have more or less of a peculiar applicability to the work required, and proving in its cost of maintenance or replacement, expensive or otherwise, according to the knowledge of conditions possessed by those responsible for laying each floor.

Maple is naturally first in favor and most frequently used. It is, however, also most expensive, and in some respects the most unsatisfactory floor. The average quality of maple being used for flooring to-day is not as good wood as the maple that was used twenty years ago, and there are now maple floors that have been down for twenty years which are in better condition than floors that have been down only a few years. Irrespective of quality, however, maple is desirable for indoor floors chiefly on account of its good appearance, long wearing and non-splintering qualities, due to the close fibre of the wood, this close fibre at the same time seeming to be the reason for most of the trouble with maple floors, as on that account it holds moisture longer, and, unless it has been treated in some proper fashion, will in from two to five years buckle, many times even to such an extent that tongue and groove separate, nail heads pull through, and the floor becomes unsightly and unsafe for traffic. Maple also seems to be peculiarly subject to rot where it is in contact with artificial heat supplied from radiators or steam pipes. It is on account of this extreme sensibility to dampness that maple is seldom used for outside flooring.

Ash, oak and chestnut will all quickly splinter, if subjected to any heavy wear.

Pine, second only to maple in the extent of its use for floors, is perhaps the cheapest and least expensive to maintain, and can be used where traffic is heavy, and as it rarely becomes buckled, offering better resistance to weather conditions, can, aside from the matter of appearance, be used for floors where none of the other woods would do so well.

Pine, however, will splinter, and after commencing the splintering advances rapidly, making the cleaning of the floor almost impossible, and very quickly rendering it unsafe for traffic.

In floors, all of these woods are just as subject to rot as they are when used for other purpose, and there does not appear to be any peculiarity in the way rot starts in a floor, the conditions and results being much the same in flooring as in any other wood, and the most expensive-economy practiced is to lay a new floor over an old one that is dry or rotted, the rot from the old floor simply penetrating the new floor with a greater degree of rapidity, and seemingly also after an old floor is covered with a new one without the old floor being taken up, the rot penetrates the rafters and beams more quickly.

The desirability of treatment for floors to prevent splintering, rotting and buckling has, of course, been recognized, and different ways have from time to time been tried, and in my experience most of these different ways have been not only unsuccessful, but many of them positively injurious, one very prevalent way being the application of boiled linseed or cottonseed oil when the floors are laid. This idea is all right as far as it goes, but I have never found that it was permanent. It does not seem to penetrate the fibre, but, remaining on the surface, hardens, and then the traffic soon causes it to scale off in a light yellow powder, leaving the floor no better able to resist rot and splintering than before application. A combination of linseed or cottonseed oil with turpentine and wax is in the same class, the turpentine only penetrating the wood, but that soon evaporates, and the traffic then causes this to scale off in the form of a dark brown powder. Paraffine wax oil seems to be more or less injurious, as this apparently destroys the life of the floor, causing a rot of a peculiar character, noticeable by small pieces of wood breaking off under wear.

Creosote and similar real preservative materials are not practical for the great majority of indoor floors for obvious reasons, and it would seem, if this field is to be covered, that it can only be through the medium of a material that is an actual preservative, that will cause the floor to which it is applied to resist dampness and splintering, and that can be applied to the floor either after it is laid or at least applied to the flooring of the building or the place where it is to be laid.

Statistics are not obtainable as to the amount of wood flooring annually consumed, but the quantity is so great that any practical way, at a cost that would be commercially practicable, to add to the usefulness and the life of wood flooring is well worth careful attention, and the concrete and composition flooring has not proven so universally satisfactory under any and all conditions, but that wood flooring will be well able to hold its own in competition with these other materials, if the ordinary trouble of a wood floor could be materially modified or overcome.

TIMBER FOR CREOSOTED BLOCK PAVING.

By Harry C. Davis.*

The success of a wood block pavement depends upon four fundamental principals. These are:

First. The quality of wood from which it is manufactured.

Second. The character of the oil used for preserving the wood from decay.

Third. The method and manner in which the blocks are treated.

Fourth. The excellence of the construction of the pavement.

While it is probably true that all of the first three of these principals are of equal importance, and the fourth of major importance, this paper has to deal only with the first, or the quality of the wood selected for the pavement. No matter how proper may be the selection of the wood, the oil or the manner of treatment, the pavement will be a failure unless the construction work is properly done.

Failures of street pavements of all kinds are frequently attributed to causes which have nothing to do with that failure. For instance, the writer is familiar with a certain street in the city of Chicago where black gum was used and the timber condemned and stricken from the specifications because of defects appearing, which were attributed, probably without the slightest reason, to the wood itself.

It is also equally true that faults sometimes exist in one of these fundamental principals which are not directly charged to it. Take, for instance, "weeping" or "bleeding." This has universally been attributed to the nature of the oil used in impregnating the blocks, and but few engineers have attempted to charge it to any other cause.

*Manager Paving Department, Chicago Creosoting Co., Chicago, Ill.

About three years ago the writer heard Mr. Andrew Rinker, city engineer of Minneapolis, state that there had been no trouble from "bleeding" in the six or seven hundred thousand yards of creosoted blocks they laid in that city. Since that time there has been a change made in the timber specifications, while the oil is practically the same as was used prior to that time. Now there are complaints of "bleeding" in Minneapolis. As usual, this defect has been attributed entirely to the oil, and so far as the writer knows no one has even suggested that the wood is in any way responsible for the condition.

In selecting a wood for paving purposes, three things should be taken into consideration. These are:

First. The adaptability of the wood to the purpose designed.

Second. The availability of the wood selected.

Third. The commercial conditions surrounding the wood selected.

By "adaptability" is meant both the probable service that will be given by the blocks manufactured therefrom, as well as the natural characteristics of the wood with respect to the manufacture of the blocks.

The writer of this paper does not intend to enter into any extended discussions of the natural characteristics of the various woods available for paving purposes. It is thought sufficient only to touch lightly upon this phase of the subject, in the hope that some of the members who are practical treating engineers will more extensively bring out these points.

A pavement, be it wood block, brick, stone, asphalt or tar, is laid for two purposes—namely, to facilitate traffic and to increase sanitation. The only feature worthy of consideration from the standpoint of this paper is that relating to traffic, and more particularly with reference to the effect of traffic upon the pavement. As this is true, it is necessary to select a wood which is sufficiently strong in texture to withstand the effects of the traffic and give a long life to the pavement.

Engineers, as a rule, are prone to be entirely too strict in their requirements. For instance, engineers of this country have been making long-leaf yellow pine the standard of perfection in a paving block. This wood has been used in probably seventy-five (75) per cent. of the creosoted block pavements laid prior to 1911, when they decided that a short-leaf pine might be used if of close growth. The change was a wise one, inasmuch as short-leaf pine, while not so strong a wood as the long-leaf, is sufficiently strong for a paving block.

There is a great deal of difference in the characteristics of the two woods. Long-leaf pine, according to Sargent, weighs 43.6 lbs. to the cubic foot, against 38 lbs. per cubic foot for the short-leaf. The specific gravity of the one is .70, against .61 for the other, while the modulus of rupture of short-leaf pine is barely 75 per cent. of the long-leaf.

The foregoing is cited simply to show that it is not necessary in selecting a wood for paving purposes to require one of the greatest possible strength, but simply to call for a timber of sufficient strength to withstand the stress to which it will be subjected under traffic.

Following this principal you will find that there are several commercial woods available for paving purposes, any of which are sufficiently strong for the purpose and elimination must come through the more technical features of wood preservation, such as the adaptability of the wood to treatment, and its power to withstand decay after treatment.

Experience has proved that in the Central West we have at least four woods which, when tested by every possible requirement, are suitable for paving purposes. These woods are Southern yellow pine, tamarack, hemlock and maple. The writer has had no opportunity to study the Norway pine. One street paved in Chicago with black gum is not considered a sufficiently conclusive experiment to warrant one to form a definite opinion.

The writer is thoroughly convinced that each of the four woods mentioned is sufficiently strong to withstand the heaviest of traffic, and from actual experience knows that each is adapted to treatment Observations made at our plant during the past year show that maple is the wood most easily treated, followed closely by tamarack and hemlock, all three greatly outclassing yellow pine in this respect.

Before proceeding to the other phases of the subject, I want to give you a few observations I have made of the results obtained by the use of these woods. For the past ten years the city of Chicago has confined its wood block pavements almost entirely to yellow pine, in fact all the streets laid prior to 1912 were yellow pine with two exceptions. These were about 1,500 yards of Southern black gum and about 8,000 yards of street car right-of-way paved with tamarack. In the past year we have laid a test intersection with maple, and about two miles of tamarack blocks. The yellow pine has given excellent satisfaction on some of the heaviest traffic streets in the country. We have one street in the loop district in Chicago paved six years ago with yellow pine, and certainly no one can say there has been the slightest failure due to any defects in the timber.

About five years ago The Kettle River Company, of Minneapolis, sold to the Chicago Railways Company some tamarack blocks which were used in paving the right-of-way on Dearborn Street, between Van Buren and South Water Street. Although the construction of this pavement is open to considerable criticism, especially the treatment around the tie rods, yet the pavement is in excellent condition to-day, and shows just as good results as have been obtained from yellow pine blocks.

A little more than a year ago our company furnished enough hard maple blocks to lay the intersection of Madison Street with Fifth Avenue, one of the heaviest traveled spots in the city of Chicago. It is estimated that the daily vehicle traffic on Madison Street is eight thousand, while that of Fifth Avenue is over five thousand. Pounded by traffic from four directions, these blocks do not show the slightest sign of wear. In fact, so satisfactory was the result that the Chicago Railways Company purchased its entire supply for 1912, specifying maple.

With reference to hemlock, I will simply call your attention to the results shown by this wood in the test pavement in Minneapolis laid under the supervision of the United States government. In a seven-year test, hemlock shows only a sixteenth of an inch more wear than the strictly long-leaf yellow pine. In compensation for this, I am reliably informed that the relative quality of yellow pine used in this test was better than that of any other wood placed in the pavement.

Certainly these instances would prove that so far as the strength of the four woods mentioned is concerned, that the engineer should have little or no hesitation in making his specification open to all. There is no doubt that hard maple is the strongest of the four, followed next by the yellow pine, and then by tamarack and hemlock. But each is sufficiently strong for paving purposes.

Little can be said on the subject of the availability of the wood to warrant the selection of any wood for paving purposes. It is necessary to assure oneself that the available supply is sufficient to fill the demand, and in considering this phase of the subject it is well to look to the future. The wood that is plenty to-day—when the pavement is planned—may be scarce to-morrow, when the pavement is laid.

One of the most important things to take into consideration is the commercial conditions surrounding the timber selected. A wood block pavement, or in fact any pavement, must be constructed as cheaply as possible commensurate with the quality required. This means that careful consideration must be given to the commercial conditions surrounding the timber

There is perhaps no better illustration of the danger involved in this connection than was evidenced in the city of Chicago in 1912. Every ordinance called for Southern yellow pine or woods equally good for paving purposes. As all know, the yellow pine market early in 1912 joined the aviation craze, and Lincoln Beachy lost every laurel he ever won. The sky was the limit, and, as a result, wood block pavements broke all records for high prices to the consumer and small profits to the manufacturer. Our company was more fortunate because of the supply of tamarack timber, which was not affected by the airship mania, and we sold every foot we had, and could have sold four times as much more had we laid in a larger supply earlier in the year.

While these pavements were soaring and being damned by every property owner who had to go up and plank down his hard-earned cash to pay his assessment, we were vainly struggling with the city to permit us to deliver hard maple, which could be purchased at a considerable lower price than yellow pine, or even tamarack. But the policy of the city was against letting down the bars, and the taxpayer paid the bill.

It is not the intention of the writer of this paper to plead for any particular wood. The writer has no favorites, and is so situated that he can furnish any wood that has yet been used as advantageously as any competitor. I am a pretty good Democrat, at least to the extent of crying free trade. I believe in an open specification. Put the Northern and Southern woods into competition and then give the taxpayers the benefit of that competition. Do not put yourself at the mercy of the Southern floods or Northern thaws. Play both ends against the middle with a stringing bet near the centre, and you will have as near a system that will beat the game as it is possible to find. Any of the four woods mentioned in this paper is good enough for a street pavement. Therefore, get the one that is most available, and that is the one that will be the cheapest.

ADZING AND BORING TIES AND THE COST OF INSTALLING PLANTS OF THIS KIND.

By James A. Lounsbury.

Railway track construction in this country has never, for any long period, been adequate to the demands made upon it. Traffic, wheel loads and speeds have continually outrun all efforts to keep the sub-structure equal to the requirements. Track improvement programs providing for a liberal margin in carrying capacity have been overtaken and passed by the growth of traffic almost before the work was completed, and therefore little relative gain has been made. This has been due to some extent to the fact that such improvements have been made under pressure, and time has not permitted the close investigation and study of the means and methods necessary to produce the highest ultimate economy, but the necessity of doing the best possible with the amount of money available for the work has probably been the chief limiting factor.

The era of extensive railroad building is practically past and future progress will be along the line of intensive development, in which the quality will be higher as the quantity grows less. The continually narrowing margin between income and operating expense is forcing railroad officials to consider details of economy which heretofore have not appealed so strongly to them.

Probably the most important step that has been taken in this direction is the rapidly growing practice of chemically treating ties in order to secure the longest serviceable life for the smallest tie investment. But the chemical treatment cannot show its maximum efficiency with the prevailing methods of handling the ties when putting them in track. The folly of paying twenty to thirty-five cents per tie for chemical treatment and then to so mutilate them by hand adzing and spike driving as to greatly reduce the beneficial effect of the treatment is too obvious to require argument.

Machine Adzing.—Of the 150,000,000 ties used annually in this country, approximately 74 per cent. are hewn and 26 per cent. sawed. Hewed ties are never straight and the face side is never a plane surface. Sawed ties are straight when first made, but go "into wind" during seasoning. This is particularly true of many varieties of hard wood. The consequence is that the rails when laid have an insignificant bearing on the tie, throwing the weight of the supported load on a very restricted area of the rail base and introducing very serious stress factors into the rail problem. Hand adzing is resorted to commonly to correct the defects in the tie surface, but this is at best only a partial remedy, and its effect on the impregnated part of the tie is destructive. The advantage of having a full and perfect bearing for the rails over the whole width of the face of every tie is evident. It reduces rail cutting, decreases the danger of half moon breaks in rail bases, reduces disturbances of the ballast and gives added firmness and stability to the track. Where plates are used it is a practical necessity to give them a full bearing on the ties, as the increased surface makes it more difficult for them to properly seat themselves under traffic. If their bearing on the tie is not parallel with the bottom of the rail they increase the danger of rail breakage, as they form an anvil upon which the impact of rapidly moving loads is received. If the point of support is along one edge of the rail base only the danger to the rail is apparent.

Boring for Spikes.—Many tests made by the United States Bureau of Forestry, by several universities and independently by a number of the railroads have demonstrated conclusively that common square spikes have increased holding power when driven into previously bored holes. These test reports are too voluminous to be reproduced here, but your attention is directed to tests made in August, 1909, at Purdue University, under the auspices of the Bureau of Forestry, by Mr. J. A. Newlin, Engineer of Timber Tests. Also to very exhaustive tests made under the direction of Mr. R. I. Webber at the University of Illinois in 1906. Conclusive tests have been made by the A., T. & S. F. Railroad, but I do not know that they have been made public. These records agree as to the main facts, but the difference in the conditions surrounding the several tests makes exact comparison difficult. It is sufficient to note that the differences are in degree only. They indicate that in the oaks, beech, gum, long leaf and short leaf pine and Douglas fir the increase in resistance to vertical pull varies from 5 per cent. to 15 per cent. in favor of the spikes in bored holes, where the holes are ⅛ inch to 3/16 inch smaller than the spikes.

It is unfortunate that there are almost no reliable data showing the comparative resistance to lateral pressure of spikes driven directly and those driven into previously bored holes. This is of even more importance than the resistance to vertical pull, as upon it depends the maintenance of gauge and the prevention of rail spreading under high speed trains. It is probable that the resistance to flange pressure is increased in much greater proportion than the resistance to vertical pull, because the spike in a bored hole has a backing

of solid wood instead of being surrounded by torn and broken down fibres, as is the case when driven directly.

The use of screw spikes, of course, makes pre-boring absolutely necessary. A number of roads are already committed to this form of rail fastening, and its extended use is only a matter of time. At present probably 75 per cent. of the ties that are bored are for square spikes. The possession of a convenient means for cheaply and rapidly doing the boring will cause the early adoption of the screw spike on many roads which would be slow to take it up under other conditions.

Of chief interest, however, to the members of this association is the great advantage from a treating standpoint of having the adzing and boring of ties done before the treatment takes place. The vital points of a tie are the parts under the rails and contiguous to the rail fastenings, and this is where the impregnation should be most thorough. In air seasoning the ties become case hardened on the outside, and this hard skin is more difficult of penetration than the portion immediately beneath. In adzing previous to treatment this more resistant portion is removed for a distance of 12 inches to 14 inches in length for each rail bearing. This permits the chemical to penetrate more freely transversely to the grain. The holes bored for the spikes give the chemical free entrance to the interior, allowing it to radiate from each hole by end grain penetration, thoroughly saturating these portions even when the tie as a whole is not given a heavy treatment. How much this saturation of the parts of the ties subject to earliest failure will increase their life cannot be measured until sufficient time has elapsed to allow accurate comparative data to be obtained, but there is no doubt that it will greatly increase the efficacy of the treatment and produce results far out of the proportion to the cost of the adzing and boring operation. It is stated by the railroad engineers who have had several years' experience with adzed and bored ties that the saving in time and labor in putting the ties in track is sufficient to pay the cost of the adzing and boring, leaving all the other advantages a net gain.

Adzing and Boring Machines.—The adzing and boring of ties has been standard practice in Europe for upwards of twenty years, and the results have proved its economy. Owing to the abundance of cheap labor in those countries, the development of machines of the highest labor-saving capacity has not been rapid. Their ties are more carefully made, and therefore machines are not required to meet such wide variations as in this country. In England the majority of ties are sawed from dimension stock and vary little in size. A range of 1½ inch difference in thickness is all that is provided for in their machines, while ours must be designed so that ties from 5 inches to 10 inches thick, and from 7 inches to 14 inches wide, may be run promiscuously. Again, their ties being practically of the same width no provision need be made for centering so that the holes will always be properly placed in the face of the ties. With our extreme variations in width, and the fact that no two ties are alike in shape, that crooked and straight ties must follow each other through the machine, makes it necessary that they be centred over the boring bits so that the holes shall be accurately placed in relation to the centre line of the face of each tie. In other words, the machine must take ties as they come, of all sizes and shapes, and automatically adjust itself to variations and irregularities, without human aid and without decrease in its rate of production.

Installation.—Two distinct patterns of adzing and boring machines are built for different methods of mounting. One is designed for installation on a stationary foundation, and the other, a more compact form, for mounting in a car. As more machines are specified for stationary mounting, this type is known as the Standard pattern. It is more open in design and accessible in its working parts than the more compact car type.

The question of which method of mounting is preferable must always depend upon yard and plant conditions, and each case must be decided upon its merits. It is probably true, however, that there are more treating plants in which the stationary mounting will give the higher economy in operation than those in which the movable type will give the better results.

The location of the stationary machine in relation to the retort house, power house, etc., in the case of plants already built, must, of course, be governed by the space that may be available, because it must be made to fit into conditions as they exist. In laying out a new plant the location is subject to control, and can be made where the least switching and handling of ties will be involved.

Wherever possible the machine should be placed between the stacking yard and the cylinders, so that all ties must pass it in their movement between those points. The trackage (narrow gauge) should be arranged so that trams from any part of the yard may be brought to the machine with the minimum amount of switching, and by-pass tracks must also be provided by which timbers not to be machined, such as switch ties, bridge timbers, piling, etc., can pass the tie machine without interfering with its supply. The tram track on the in-feed side of the machine should be about one foot higher than that on the delivery side, and should run out to a spring switch, so that an unloaded tram, given a start, will run by gravity past the spring switch, reverse its direction and return on the discharge side of the machine ready to be loaded for the cylinder. The space required between these supply and delivery trucks should never be less than 32 feet centres when the ties are to be taken from the tram and placed on the machine conveyor by hand. If the dumping hoist and the skid are employed the minimum distance between track centres is 46 feet. These dimensions apply only to the machine without the cut-off saw attachment. If the latter is required, six feet should be added to the track centre distances.

Where drainage will permit, the best form of foundation is to enclose a space 11 feet x 20 feet with a concrete wall, the interior being excavated and a cement floor laid. The side walls should be 7 feet to 8 feet high to give good head room below, as in the basement so formed the 50 H. P. motor for driving the machine is placed, together with the shavings exhaust fan. The top of the foundation should be about three feet above the grade line, making the actual excavation only about five feet deep. Steel I beams and 4 inch plank floor form the support for the machine. The weight of the latter is 20,000 pounds. This form of foundation is not always necessary, but is the most advisable when conditions permit.

Machines designed for mounting in cars perform the same operations in practically the same way, but, as stated before the dimensions are held down in order to bring them within the limit of width of a wide box car, having extra wide doors through which the conveyors extend. The original installation (two machines on the Santa Fe and one on the Northern Pacific) were all of this type.

The car used for this purpose should be of steel underframe construction, forty feet long 9½ to 10 feet wide, and of 40,000 pounds load capacity, and not less than 9 feet high in the clear. The cars are usually made self-propelling from the clear. The cars are usually made self propelling from the same source of power which drives the machine, a clutch being provided by which the machine is disconnected and the car axle drive thrown into gear when the car is to be moved. As the car is commonly designed to move about the tie yard

only, the speed is kept down to about three miles an hour. The principal movement being only from stack to stack, no higher speed could be used to advantage.

The kind of power to be used in these movable plants is often a somewhat troublesome problem. Electric drive is by far the most reliable and satisfactory if it is available. In yards using electric switching locomotives and strung with trolley wires the application of electric power is easy, but where this is not to be had resort must be made to some other source of power, usually a self-contained gasoline engine of about 60 H. P. installed in the car with the machine. This gives satisfactory results, but requires more careful management than would be necessary with an electric motor.

The track arrangement in a yard already laid out is, perhaps, the most important factor in determining the comparative merits of the stationary and car mounting. The usual system, a three-rail track between the tie piles, would make it necessary for the trams to follow directly behind the machine car, a position which is not convenient for loading by the machine conveyor, as a right-angled change of direction must be made by the ties in their progress from the machine to the tram. At the Somerville plant the Santa Fe people have a temporary track 60 to 90 feet long which is placed between the tie pile and the three-rail track, and upon this the machine car is placed. One rail length after the other is moved forward and laid ahead of the car. This leaves the tram track clear, and trams can be brought up to the side of the machine car, allowing the conveyor to discharge the machined ties directly into them. On the feeding side the ties are thrown down from the top of the piles and placed directly on the in-feed conveyor, so that one handling is saved by the movable machine arrangement. This, however, is offset by the time lost in changing the position of the car. As an average it is probable that about one-third more ties can be put through the stationary machine in a day than through the movable plant.

The subject assigned to me by your program committee included the cost of installation of machines for adzing and boring ties, but this is a difficult thing to cover without definite specifications. It is more an engineering problem than a manufacturing one, as the conditions are not the same in any two cases. The cost of the machine itself may vary as much as $1,500.00, depending upon what is wanted in the number of boring spindles, the length of conveyors, and whether or not the machine is to be provided with cut-off saws, branding device, dumping hoist and other special features. The cost of the power plant may also vary between wide limits. A steam engine or boiler, or a gasoline engine, costing much more than an electric motor. The building may be sufficient to protect the machine only, or may be large enough to cover both tracks and give protection to the tie feeders and loaders. One machine in the South is placed upon a foundation of heavy creosoted timbers laid on top of the ground and is covered by an open shed. Another on the Pacific Coast is placed on the end of a dock of piling, eighteen feet above the ground, into which the piles are driven. It is all a question of the governing local conditions, and how much money the purchaser is willing to spend. Some plants have been installed complete for $10,000.00, and the cost of others has run as high as $15,000.00, but in the long run the most thorough work is the cheapest, the saving in operation and maintenance paying large interest on the additional cost.

Does adzing and boring pay? It is believed that the increase in life that may be expected from ties adzed and bored before treatment will not be less than one-third, but to be conservative we will consider that it is only 15 per cent., or say 21 months of added service. In the case of a railroad using 1,000,000 ties a year, costing when treated, delivered and put in track 85 cents each, the total saving in tie renewals will amount to something over $100,000.00 a year. In comparison with the cost of equipment, is this not worth while?

THE PRELIMINARY TREATMENT OF TIMBER TO INSURE A MORE EVEN AND SATISFACTORY IMPREGNATION WITH CREOSOTE.

By David Allerton.

I will premise by stating that my title does not exactly state what I have in mind. I cudgelled my brains, but could not arrive at anything better in the limited time at my command, which is only a few hours. I must also say that what I may suggest does not conflict with any existing method or process. It was brought forcibly to my attention last spring, although it has long been a subject of study with me—that is, to find a method by which the great disparity often noticed, and in fact usually observed, of the great difference in the receptivity of various ties or timbers in a given charge. Mr. Goltra, in his work, has shown graphically the various degrees of absorption in a charge of ties as usually treated; of course, there will always, under any condition, be a considerable variation in a charge of carefully selected and sound ties and the same where structural timbers are treated, but is there not possible some method of preliminary treatment by which, without impairing the strength of the wood, the structure of the ties or timbers can be rendered more homogenous, so that with a given amount of oil the penetration will be more uniform? I assume that wood of the same species or variety, where the difference in penetration is marked, often as we have all observed in different parts of the same piece, that portion or piece which takes the oil readily would not be changed in its quality of absorption, but that the more difficult structure could be rendered more susceptible to impregnation, assuming, for instance, in the case of ties with a given quantity of oil—say the usual amount; 2½ or 3 gallons per tie—much more even penetration.

Of course, heat is a necessity in any mode of procedure, and the proper temperature and regulation will undoubtedly be the most important factor in solving this problem, as it is well known that to get good results from hot oil with cold wood is impossible (bear in mind I am not speaking of soft pine or other soft woods that take treatment under any conditions). But here arises another question. Suppose oil is dropped on the cold wood at a temperature of 190°F. and the heat in the cylinder again raised to 180°, how far into that wood is the temperature 180 degrees. That, of course, depends on the diameter of the pieces. With large dimension timbers it is a very little ways, unless a long time has been consumed, and even then the centre of the wood is very much cooler than the outside. This is one reason why large timbers such as 12 inch by 12 inch, or 12 inch by 14 inch, are very hard to treat. Taking this into consideration, I think the next most important factor will be air in conjunction with the heat in current, or compressed moist or dry, and perhaps attenuated by more or less vacua, as the situation will be found to demand, and in all probability the process will be varied somewhat for different species.

I assume that all will agree that the better seasoned the great majority of wood is the easier and more satisfactorily it can be treated, therefore I also assume that a preliminary treatment can be found, and very likely some of you have discovered the means by which, with the necessary adjuncts to the treating cylinder, or in accessory and less expensive cylinders, by use of which valuable time can be saved and the wood can be prepared to accomplish the best results.

CONTENTS OF THIS ISSUE.

HEIGHT OF OFFICE BUILDINGS.

Canadian cities are rapidly approaching the conditions of congestion of traffic prevalent in cities of the United States. With the increase in land values the height of office buildings has gone up. Already the people are beginning to object, and drastic action must be taken in the near future in the larger of our cities if the sky-scraper is to be kept within reasonable limits.

In a recent article in a contemporary it was stated that the tall office building is the direct and logical result of congestion in large cities and the corresponding high values of building sites, which bring with them large rentals, justifying the greater investment necessary to increase the rental space by upward extension.

Since the fixed charges and maintenance of these buildings are extremely high, and few, if any, of them are constantly filled with tenants, the highest ones are almost invariably undesirable financial investments, and it is understood that exceedingly few of them in New York City return as much as 4 per cent. on the capital invested. Few of them are owned by private individuals, but in the majority of cases they are built by construction companies organized primarily to provide safe security for large sums of money loaned by insurance companies and other great corporations to the constructors of the building.

In New York, and probably in Chicago, it is likely that the maximum percentage of net returns for the capital invested is secured from buildings sixteen to twenty stories in height, of which there are scores, besides a considerable number materially higher, and some twice or three times as high, all of which have been erected within the last twenty-five years, since the production of structural steel and the high development of the passenger elevator, combined with improvement of fireproofing, have made their construction and operation possible and reasonably safe.

Their construction in small cities is seldom or never necessary, or justified by financial considerations, and it is more than doubtful whether the construction of these tallest examples is justifiable under any other consideration than that for a desire for notoriety, or whether they should be encouraged, or even permitted, in great cities, where alone there is much tendency to build them.

The principal objections to them are the enormous increase which their thousands of tenants cause in the congestion of the streets and of the traffic lines, the disfigurement of streets, the obstruction of light and air to the street and adjacent buildings, the great danger of disaster through panic among their tenants and the extreme difficulty or impossibility of adequately fighting fire in their upper stories. There is also a remote possibility of their destruction and fearful fatalities through earthquakes or cyclones.

The following is the text of a resolution presented before the Board of Trade of Toronto at their last meeting:—

> "The Council of the Board of Trade regrets exceedingly the frequent setting aside of the city by-law limiting the height of buildings in Toronto to ten stories, or one hundred and twenty-eight feet, and would strongly urge upon the city authorities the need for strict enforcement of such limitation, because, in the opinion of this Council, the steadily-increasing height of skyscrapers constitutes a serious menace to the public health, especially of those

whose work must be done in the lower stories away from the sunlight; it also adds unnecessarily to the already great congestion in the narrow down-town streets and unduly concentrates land values at or near a few leading corners, this concentration of values, in turn, making necessary still higher structures to meet the increasing ground rents.

"It is further resolved that a committee of the Board of Trade Council be authorized to wait upon the City Council and present this resolution."

As we have noted from time to time in these columns, these structures are not justified. The height of office buildings should not be fixed by the caprice of city councils. A fixed, inflexible rule should be followed, such as is in use in many parts of Europe, that the height shall not be greater than one and one-half times the width of the street on which it was erected.

McGILL GRADUATES' ADDRESSES WANTED.

A list is given below of a number of graduates of McGill University, Montreal, whose addresses are not in the University records. It will be greatly appreciated if information can be given regarding the addresses of any of these men, or any references which may lead up to the obtaining of the same. Communications should be addressed to Professor N. N. Evans, Secretary of Applied Science Graduates, McGill University, Montreal.

Graduates Whose Addresses are not Known.

1859—Crawford, Robert.

1860—Kirby, Charles H.; Walker, Thomas.

1889—Tuplin, Jas. P.

1892—Wainwright, Jas. G. R.

1893—Robert, Alph, M.A.; Simpson, Lincoln.

1894—Lambert, Frank.

1895—Dobson, Gilbert S.; McNaughton, Peter.

1897—Edward, John Ross.

1898.—Ainley, Chas. Newth; Atkinson, Wm. J.; Scott, James H.

1899—Pitcher, Norman C.

1900—Robertson, Philip W. K.

1901—Donaldson, Hugh Walter.

1902—Baird, Alexander; Jackson, Philip T.

1903—James, Bertram; Savage, George M.

1904—Cardew, John Haydon; Devlin, Cecil G.; McPhee, James McDonald; Roffey, Miles Herbert; Wilson, William D.

1905—Johnstone, George A.

1906—Livingston, Douglas C.; McIntosh, Robt. F.

1907—Brown, S. Barton; Gamble, Clark W.; Otty, George N.; Tupper, Fred McD.; Wright, George R.

1908—Cattanach, F. W. C.; Pratt, Austin Craig; Scott, George F.

1909—DeLancey, James A.; Grove, Humphrey S.; Hagne, Owen C. F.; Lundy, Thos. H. D.; Whyte, Herbert B.

1910—Cloran, J. H. D.; Elkins, Robert H. B.; Goodstone, Arthur S.; Reid, Archibald C.; Slavin, Reginald V.; Stuart, Aleg. G.; Sweetman, Samuel.

1911—Alward, Ernest T.; Murphy, William H.; Planche, Clifford C.

1912—Henry, Robt. A. C.; Sanderson, Chas. W.

TESTS OF PLAIN SEDIMENTATION OF SEWAGE.

Plain sedimentation of sewage instead of chemical precipitation has been tried with promising results at one of the large sewage-treatment plants of the London County Council. The following slightly condensed statement is from a recently revised pamphlet edition of the "Main Drainage of London," by Sir Maurice Fitzmaurice, chief engineer of the London County Council:

The main drainage committee conducted experiments at Barking during the months of May, June, July and August, 1911, with the object of finding out how the effluent would be affected if lime and iron were not added to the sewage, and if some alterations were made in the times and methods of cleaning out and removing the sludge from the precipitation channels. The usual interval between the successive cleaning out, or the "channel hours" of any one channel, is 60 hours. Shorter interval, viz., 30 hours, was adopted during these experiments so as to compare with the longer interval usually adopted. The general result of the experiments was that, as regards matters in suspension, almost the same purification was obtained without chemicals by reducing the channel hours to 30, as is at present obtained with the use of chemicals and with 60 channel hours. During the whole period in 1913, while these experiments were being carried on, no complaint was received as regards the condition of the Thames, notwithstanding that the summer of 1911 was exceptionally hot, and the amount of river water coming down was exceptionally small.

The experiments have been continued in the present year (1912) during the months of June, July and August, and the results obtained corroborate generally those obtained in 1911. The Port of London authority takes from time to time samples of the effluent discharged into the river, and during the months the experiments were being carried on they made no complaint as regards the quality of the effluent. In fact, the reports of that authority on the effluent during the experimental periods were of a more satisfactory character than either before or after, when the station was being run in the ordinary way.

The chemicals themselves add considerably to the amount of sludge that has to be dealt with, and it is possible that, owing to chemical combination, the bulk of the sludge may be increased by more than the amount of chemicals used.

If the use of chemicals were altogether discarded a very large saving in working expenses would result. The saving would not, however, amount to as much as the discarded chemicals would have cost, as the expense of increasing the flushing staff so as to reduce the channel hours from 60 to 30 has to be taken into account.

I cannot say exactly what the net saving would be, as the costs of lime and iron vary from year to year, but there is no doubt that, considering both outfall works, it would amount to between £15,000 and £20,000 a year [$73,000 to $97,000].

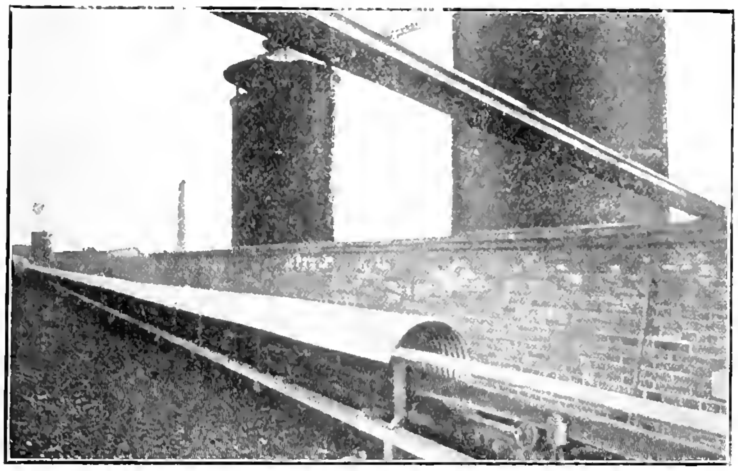
The results of the experiments made in 1911 were given in detail in a report presented to the Main Drainage Committee on November 23, 1911, and the results of the experiments made this year will be presented in a detailed report later on. I am strongly of opinion that one of the outfall works, at all events, should be run completely without chemicals for one year after the termination of the present contracts for chemicals; and from the data thus obtained it may be found advisable ultimately to discard altogether the use of chemicals for precipitation.

FOUNDRY CONVEYER SYSTEM OF MASSEY-HARRIS COMPANY, LIMITED.

The Massey-Harris Company, Limited, of Toronto, Ontario, have just completed the installation of a system of conveyers. These conveyers are installed for handling material in connection with their foundry and will greatly simplify and reduce the labor in this part of their plant.

A gravity discharge conveyer-elevator, 40 feet between centres vertically, and with a horizontal run of about 20 feet, is used, and coke is delivered to this by means of a hopper at the base, and is raised to the upper run from which it discharges to a belt conveyer serving the east cupolas, or into a hopper serving the charging cars of the west cupolas. This gravity discharge outfit is a very excellent type of conveyer-elevator for comparatively small capacities and it is used very extensively in coal pockets and fueling systems. It consists essentially of a series of "V"-shaped buckets carried between steel or malleable chains and attached rigidly to the links. The buckets on the ascending run are carried upright, so that the material is carried in the buckets, and on the horizontal runs the buckets push the material along in a steel or concrete trough. This arrangement allows for a very simple discharge at any point by merely opening a gate in the bottom of the upper trough.

The belt conveyer receiving from the gravity discharge is shown in the illustration. This conveyer is 18 inches wide and 350 feet between centres and runs horizontally along the top of the building for the greater part of its length.



Eighteen-inch, 350-foot Belt Conveyer at the Massey-Harris Company.

The method of housing the conveyer, employed by this firm, is shown only partially completed. This method is an inexpensive and yet very effective means of covering the conveyer and is applicable to any gallery conveyer. The drive of this conveyer is located at the head end and delivery is made into a chute serving the cupola charging cars similar to those receiving from the gravity discharge conveyer.

A conveyer independent of the other two is located in the basement of the foundry and delivers sand, coke, and broken stone from the track hopper into several of the storage bins. This is also an 18-inch belt conveyer, 50 feet between centres, driven at the tail end from a five-horse power motor suspended from the ceiling. This motor also drives the 24-inch, 13-foot, apron feeder, which is located on the other side of the basement wall beneath a 12-foot track hopper. At the head end of the conveyer is located a rotary cleaning brush, which cleans the return belt, removing the fine sand and the coke dust, preventing their accumulation on the return carriers and preventing the different materials carried from becoming mixed one with the other. This cleaning brush is a standard arrangement and is always located at the head end of the conveyer directly back of the head pulley, and is driven from a sprocket on the head shaft. The mechanism is self-contained and dust-proof and may be applied to any size brush and any size of conveyer. A web sprocket is used cast integral with an internal gear which meshes with a pinion on the brush shaft. An adjustable weighted lever arm provides the proper tension for the brush against the belt and automatically takes up the slack as the brush wears down.

This conveying system, consisting of four conveyers, was manufactured by the Stephens-Adamson Mfg. Co., to meet the special requirements of the Massey-Harris Company, Limited. The entire equipment was designed by Mr. Edwin J. Banfield, 120 Adelaide St., West, Toronto, Ontario, who is a special representative of the Stephens-Adamson Mfg. Co. in Ontario.

THE NEW CANADIAN PACIFIC RAILWAY SHOPS AT OGDEN, ALBERTA.

The main locomotive shop building contains the erecting shop, machine shop, blacksmith shop and boiler shop. The erecting shop will be of the transverse lift-over type, and will contain 35 bays of 22 feet each. Its entire area is served by travelling electric cranes carried on two levels. It is of structural steel frame on concrete foundations. The exterior walls up to window sills are of concrete, and the walls which are carried on steel members of hollow tile plastered. It is heated by indirect fan system distributed by concrete and tile ducts.

The department for making repairs to locomotive tenders, steam shovels, lidgerwoods and other maintenance-of-way equipment, is contained in an L-shaped building, 80 x 340 feet, and is equipped with a high-speed 20-ton travelling crane having two 10-ton trolleys. There will be a depressed track carried along the end of the wheel storage tracks outside, to facilitate unloading and loading wheels and axles. The building is of structural steel frame with steel roof and trusses and its general construction will be similar to the main locomotive shop.

The storehouse and office building is 250 x 60 feet, two stories, with offices at one end three stories high. It contains an electric elevator, vaults and platform scales. It will be parallel with the main building, the space between to be spanned by a high-speed travelling crane, which will handle all material to and from the cars and from the storage place that is provided between the storehouse and the erecting shop. The concrete foundation is carried up to bring the floor of the storeroom to car door height, and the walls above are brick and concrete blocks, supported on concrete foundation walls, the woodwork of heavy timber comprising slow burning mill construction. The building is heated by an indirect fan system, and sprinklers are installed for fire protection.

The oil house, 102 x 40 feet, is similar in construction to the storehouse.

The foundry is 204 x 80 feet, of similar construction to the main building, having two bays, one of these of higher cross section to be served its entire length with high speed travelling electric crane. Jib cranes attached to building columns are provided and so arranged that they may be moved from one location to the other if desired, handled by the travelling crane. In the side bay of lower cross section is provided for core making and snap moulding floor. The charging floors and cupola will be located in the centre of the low bay. The heating is indirect fan system distributing

through galvanized iron pipes carried overhead. Steam, air and water service, including fire protection and drinking water are provided. The location of this building alongside yard crane will enable the unloading of scrap and pig-iron to be taken care of by the crane. This close proximity of the foundry to the crane will also reduce to the minimum the handling of the castings from the foundry to storage or to the main shop or loading for shipment.

The pattern shop, 100 x 30 feet, for pattern storage and pattern making will be of similar construction to storehouse.

The coach repair and paint shops are contained in one building, 362 x 146 feet, having 15 tracks at 24 feet centres. It is of slow burning mill construction having concrete block or hollow tile walls on concrete foundation. It is heated with the indirect fan system distributed underground in concrete and tile ducts, and protected from fire by automatic sprinklers.

Transfer table and pits. For serving the coach shop there will be installed a 75 ft. transfer table of 150 tons capacity, equipped with an electric motor. The transfer pit and track foundations are constructed of concrete. This pit will extend far enough at either end of the building to provide entrance and egress at both ends.

The freight car repair shop, 300 x 231 feet, is designed to contain eight repair tracks placed in pairs giving room for an industrial material track between each pair of tracks. A brick wall partitions off a wall 50 feet wide along one side which contains the blacksmith's forges, wood working and machine tools, the heating plant and foreman's office. The locaton of this building alongside of the lumber yard will permit of handling lumber so that it can be passed through into the shop without rehandling. An overhead trolley beam will be erected to permit of handling timbers with a trolley into the shop. Material bins will be located convenient to the building for storing material used on the cars repaired in the shop. The building is constructed with walls supported of concrete foundations having steel posts supporting steel trusses. The roof is of saw toothed construction to permit of good light during the day. The general construction of the building otherwise is the same as that described for the other buildings, including fire sprinklers and indirect fan system for heating.

Yard crane. The entire area, about 80 feet wide between the storehouse and locomotive shop, will be served by a high speed travelling crane of 10-ton capacity. The runway for this crane will extend for more than 1,200 feet, passing down alongside of the foundry and covering the space occupied by the scrap dock. One of the storehouse tracks extends through under this crane, giving ample space for the storage of heavy material alongside of the storehouse, foundry, and locomotive shop. By this arrangement heavy material will be unloaded, stored and rehandled to the shop or loaded out again for shipment by the crane practically eliminating manual labor in the handling of heavy material.

The power house, 104 x 84 feet, will have sufficient space for boiler equipment necessary to provide steam for heating the shops and for such other purposes as steam will be required throughout the shops. The building will have brick walls carried on concrete foundations with steel roof trusses and supports for coal bunkers. The chimney is of reinforced concrete. Overhead bunkers for coal are provided and concrete dumping pit for unloading coal. An overhead storage bin for shavings will also be provided and another storage bin for cinders from which bin they can be discharged by gravity into cars alongside of the building.

The planing mill, 300 x 80 feet, will contain the woodworking machinery having a track extending through longitudinally to permit of movement of material to the various machines with the minimum amount of handling. The building will be located so as to be convenient to the coach shop and freight car shop. The lumber yard will be located back of and at one end of the planing mill. The building is of hollow concrete blocks carried on concrete foundations with steel roof trusses covered with 4-inch plank sheathing. The heating is by the indirect fan system. Provision has also been made for lavatories, metal lockers and suitable piping for distributing compressed air and water, including fire protection and drinking water.

The mess building is about 150 x 30 feet, of one story, except a portion of the centre which will be carried up two stories. Miscellaneous buildings. Inclnded in the scheme are dry kiln scrap docks, material bins, plate and iron racks, and other buildings in the yard.

CEDAR RAPIDS POWER AND MANUFACTURING COMPANY.

Arrangements in connection with the financing of Cedar Rapids Power and Manufacturing Company have been completed and a circular issued to Montreal Power and Shawinigan shareholders, announcing the subscription terms. There has been no change in the plan originally announced. Montreal Power and Shawinigan shareholders are to be given the right to subscribe to an issue of about $8,500,000 five per cent. bonds of the Cedar Company, in the proportion of 30 per cent. of their respective holdings. The bonds, as first announced, will be issued at 90, with a bonus of 25 per cent. common stock. If the bonds hold around the issue price, and the Cedar Rapids stock sells at 60, subscription privileges would be worth about $5 on each share of Montreal Power and Shawinigan stock. Cedar Rapids stock sold the other day at 70 in private transactions.

The circular states that out of the first instalment of 120,000 horse-power, 60,000 horse-power has already been sold to the Aluminum Company of America and 20,000 to the Montreal Light, Heat and Power Company, and that the profits from this will provide for the operating expenses of the company, the interest on the issue of $8,400,000 bonds now offered, and leave a substantial surpius against the common stock of the company. These earnings will be greatly increased by the sale of the 40,000 horse-power remaining from the first installation as well as from the power to be developed in the second installation. This latter amount will be from 40,000 horse-power to 50,000 horse-power, and according to one statement should provide a profit of about $20 per horse-power.

Of the above bonds and stock the shareholders of the companies would divide as follows:—

	Bonds.	Stock.
Montreal Light, Heat and Power Company	$5,100,000	$1,275,000
Shawinigan Water and Power Company	3,300,000	825,000
	$8,400,000	$2,100,000

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended January 7th:—

	1913.	1912.	Increase or decrease.
Canadian Pacific	$2,140,000	$1,602,000	+ $538,000
Grand Trunk	850,889	735,888	+ 115,001
Canadian Northern	341,500	289,200	+ 52,300
Temiskaming & Northern Ontario	26,561	26,622	— 61

POWER PRODUCTION IN NORTHERN ONTARIO

Steam power has been almost wholly displaced by hydraulic power delivered either by the electric current or in the form of compressed air, for the operation of Cobalt mines and works. Most of the mines formerly using steam retain their plants for use in case of emergency, but the regular employment of steam is now confined to small and isolated properties.

An amalgamation between the companies producing power on the Montreal River has been effected, the Cobalt Power Company and the Cobalt Hydraulic Power Company uniting to form the Northern Ontario Light and Power Company, Limited. This arrangement enables the plant at Hound chute to confine its supply to electrical energy only, while the Taylor compressed air system installed at Ragged chute fills the contracts for compressed air.

Mines Power, Limited, whose development on the Matabitchewan was first in point of time to put electric power into Cobalt, has changed its name to the British Canadian Power Company, Limited.

On both the Montreal and Matabitchewan Rivers, though the shortage of water was not so marked during the winter of 1911-12 as it was in the previous year, experience has shown the present means of conserving the freshet flows to be insufficient for the steady delivery all the year round of the maximum quantity of power.

The watersheds of the Matabitchewan and the Montreal have both their peculiarities. The former is not extensive, being restricted on the north by that of the Montreal, and being still further narrowed by the tendency of the river to approach the Montreal as it nears its mouth, the actual entrance of the two rivers into Lake Temiskaming being only a few yards apart.

For this reason, strict economy must be practised in the use of water, and the company has found it necessary, in addition to the reservoirs already in existence, to erect dams at the outlet of Bear, Cross and Macdonald Lakes. When these are completed, practically all the natural storage grounds on the stream will be under control.

The Montreal is a longer and larger river than the Matabitchewan, but the area which it drains is lessened by the doubling, tortuous course which it pursues, especially in its southern branches.

It receives a portion of the overflow of Lake Temagami through the northern outlet of that lake, the main discharge of which is to the south by the Temagami River, a feeder of the Sturgeon.

Being thus situated on the height of land, the waters of this large and important lake, if conserved, are capable of considerably augmenting the water power of either or both the streams into which it empties. It is also evident that by adjusting the height of the dams at the northern and southern outlets, a larger or smaller proportion of the total discharge from the lake could at will be diverted into either system.

There are important hydraulic developments on both streams, on the former for power used mainly in the mines of Cobalt, and on the latter for the operation of pulp and paper mills at the town of Sturgeon Falls, reports Mr. T. W. Gibson, Deputy Minister of Mines, in the 21st annual report of Ontario's Bureau of Mines.

This situation is indicative of the classes of questions to which the rapidly increasing use of water power derived from the rivers of Northern Ontario is giving rise. But there is yet another, and very important, element in the situation.

For many years, these rivers have been used by lumbermen to float their logs to market, and their right to employ them for such purposes has been repeatedly confirmed by the legislature of the province.

Indeed, notwithstanding the extension of railways into the northern forests, and the increasing use which is made of them to transport logs, pulp-wood and other forest products to the place of consumption or manufacture, it is not easy to see how the great lumbering industry of Ontario could be carried on without the free use of these waterways.

There is nothing incompatible between the employment of flowing water for the carriage of sawlogs and its utilization for the development of power. But it is quite apparent that the presence of two distinct interests, each requiring the use of water, but for a different purpose, is likely to be productive of friction.

When the spring thaws and rains melt the snow and ice, and let loose the floods, the lumberman seizes the opportunity to get his "drive" to market. His logs in the water, he lifts the "stop-logs" from the dams and gives rein to the torrent that it may hurry his logs to their destination. Every consideration must yield to this—the logs must come down, for to be "hung up" means in most cases that another year will elapse before the logs will reach the saws, and also a loss in interest and the sinking of water-logged timber. The main body past, the rear-guard of his army "sweeps" the "tail of the drive," in other words, gathers up those logs which have stranded in shallow places, or have been caught by the rocks or other obstructions.

This demands a fresh draught on the dammed-up lakes, in order to carry the "tail" down stream, and the freshet season may well be past, or nearly so, before the lumbermen's use of the river is over for the time.

It is obvious that the owner of a water power on such a stream will find it difficult to obtain a maximum of power. The water is hurried away, which might have turned his turbines during the dry season, and his chances of equalizing the flow to the best advantage are correspondingly reduced. The situation is one which suitable legislation may be required to meet.

Much may be accomplished by co-operation between water power owners and lumbermen, by improved log-slides requiring a minimum of water to operate them, by deepening river channels, and removing obstructions, etc., but it may also be necessary to provide some means of adjusting the relations between the lumbermen and water power owners, so far as the use of the water is concerned, and also between the various users of power on the same stream, whose interests may conceivably come at times into conflict.

INDUSTRIAL ACCIDENTS.

According to the record of industrial accidents maintained by the Department of Labor, 97 workmen were killed and 357 injured during the month of December, 1912, as compared with 114 killed and 359 injured during the month of November. The greatest number of fatal accidents occurred in steam railway service, building trades and navigation, the figures being respectively 20, 17, and 12. The largest number of non-fatal accidents occurred in steam railway service, there being 131 employees injured, followed by the metal trades with 75 injured. The disasters of the month involving the death of more than one workman were a mountain snow slide at Fernie, B.C., by which six employees of a coal mine were killed and eight injured; an explosion in a pulp mill at Grand Mere, Que., by which four men were killed; and the drowning of four sailors off Yarmouth, N.S., during a storm.

THE EPIDEMIC OF TYPHOID FEVER IN THE CITY OF OTTAWA.*

By Charles N. B. Camoc, B.A., M.D.

In the city of Ottawa there have occurred two outbreaks of typhoid fever within eighteen months. This is so unusual an occurrence in our present knowledge of hygiene and sanitary engineering that it is no longer of local interest merely, but attracts the attention of physicians and sanitary engineers the world over. Besides sharing with the medical profession this general interest, my attention was specifically directed to the epidemics by being consulted by several citizens of Ottawa regarding the safety of residing in that city during the coming year.

Through the courtesy of some of the government authorities I was enabled to acquaint myself with the conditions leading up to the outbreak. As the whole matter is under investigation, to be reported upon later, I will not attempt here to deal with these conditions in detail, but will state some general facts regarding the dangers, to the community at large, which such epidemics occasion.

Typhoid is a preventable disease—its cause and mode of transmission are among the best known to the science of medicine; where the measures for prevention have been intelligently and conscientiously carried out, typhoid fever, in epidemic form, does not appear.

Transmission of Typhoid by Individuals.—The germ is carried and transmitted by individuals in the following ways:

(1) By those who have sufficient resistance to entirely neutralize the poisons and who are therefore not ill. Such individuals (immunes), though they discharge the organism in virulent form, show no other sign of the disease.

(2) By those who have only enough resistance to partially neutralize the organism, and who are, therefore, partially disabled. Such individuals (walking cases) discharge the organism in virulent form and the sequels of the disease may develop in as severe a degree as in typical cases.

(3) By those who have passed through a typical attack and have recovered. These and the walking cases may harbor the organisms for months or years. Such individuals (typhoid carriers) discharge the germ, in full virulence, from time to time.

FORMS OF THE DISEASE.

The disease appears in two forms::

1. The Sporadic Form.—This is usually traceable to some source outside of the locality in which the disease appears. For example, people returning from travel or from a summer resort, may bring in their systems an infection which runs its course and is not found beyond that particular group of persons. The Fests in Germany and the fairs and exhibitions in other countries are frequently the means of receiving and transmitting such an infection. This is also true of soldiers returning from campaigns. It will probably be a long time, and then possibly only through vaccination, before such outbreaks can be prevented. In all outbreaks it is possible for carelessness on the part of those in attendance upon the sick to extend the infection to themselves and others. This occurs through every point of contact between the fecal and urinary discharges of the typhoid patient and the alimentary tract of the uninfected individual. Such transmission is the fault of the physicians, nurses and attendants and is exclusively chargeable to them. These outbreaks, claiming their complications, sequels and mortality with the same exactness as the largest ones, are none the less tragic, but public opinion is not, as a rule, aroused.

* Issued by the Commission of Conservation, Ottawa.

Of late years the medical profession, without the goad of public opinion, has diligently striven to prevent such, and has incorporated into every medical and nursing school the training which will enable physician and nurse to safeguard the community against such transmission.

2. Epidemic Form.—Under this head comes the Ottawa visitation. It is hardly necessary to mention the less common causes of such an epidemic or to describe its features. The two outbreaks through which Ottawa has passed were caused by the commonest and best understood of all the causes of disease—namely, the contamination of drinking water by sewage. In other words, that which is scrupulously avoided in the care of the typhoid case, was, by the contamination of the Ottawa water supply, brought about in the grossest possible way.

While nurses were disinfecting discharges and sterilizing the utensils of those known to have typhoid, thousands of other persons, harboring the germ in one or the other of the ways referred to above, were transmitting organisms through the foul water directly into the alimentary tract of innocent victims.

Ottawa is outwardly a beautiful city. It is the seat of the government of Canada, a country rapidly striding into international prominence. Her people, by ever-increasing railway and steamship systems, are traveling, not only through Canada, but also through the United States and other countries.

From the modes of harboring the organisms given above, it will be seen that during and after such epidemics as Ottawa has had, every individual from the seat of outbreak may be a menace, not only to his own community and country, but to any which he may visit. The typhoid epidemic to-day is an unpardonable crime against the world. It is scientifically punishable under the sixth commandment. By scientifically is meant that science has proven that typhoid epidemics are preventable by well known and thoroughly tested methods, which, if not adopted, render the authorities guilty of murder. The command to adopt such measures should be coupled with the charge, "Thou shalt not kill."

Prevention of Typhoid.—In no other disease has science so clearly and so simply pointed out the methods of prevention. The stage of experiment in this matter has long passed.

Smallpox, yellow fever, cholera and typhus, from being a constant menace to society have become, through the work of science and sanitary engineering, almost unknown.

Tuberculosis, in spite of the persistent ignorance of some communities, is, in its severer forms unknown, and from being looked upon as an inevitably hopeless disease is now among the almost certainly curable. Diphtheria and malaria also must be mentioned in this list of curable and preventable diseases. To acquire these results, the highest type of scientific acumen, the sacrifice of life, the expenditure of enormous sums of money, and legislation, municipal, national and international, have been necessary.

To prevent typhoid, on the other hand, two things only are necessary—two things long recognized as essential to the health of any community—pure water and proper drainage. The official report shows that the Ottawa epidemics, claiming their hundred and fifty-six deaths, were due to the failure to supply these requirements. To this list of the dead must be added those who will suffer from many sequels now known to be directly due to the typhoid organisms, some being incapacitated for years with consequent poverty and suffering, the full story of which will never be known.

To this also must be added that host of victims stricken down by the typhoid carriers and walking cases, emerging from such an epidemic. These latter can transport the germ

in its full virulence to any part of the world, thus connecting the negligence or ignorance of the municipal authorities in one locality with the hideous tragedies of a typhoid outbreak in another, far removed from the original source of infection

Necessity of Federal Regulation.—It costs the government of the United States $18,000 to complete the education of an officer for the navy. After the most thorough and searching examination, the candidates are selected to serve in maintaining the nation and protecting commerce. The same is true to a large extent of the army. Why should an army and a navy be maintained against possible destruction to empire or commerce while a national menace to life is met by partially prepared or ignorant local authorities? Why should not the maintenance of a National Health Department, equipped with men prepared with the care given to the education of the navy or army officer be considered obligatory? No such national safeguard exists, except in quarantine stations. There is, as it were, a Foreign Office but no Home Office or Department of the Interior for health matters.

Our present system is analagous to despatching a body of city police to meet an invading army or to attack an enemy who had seized some important town. In a military sense the idea is ridiculous, yet this is exactly what is done in coping with a national enemy like typhoid fever. At present, in Canada and the United States, it is not possible for an expert with the authority of the Federal Government to compel a small city whose water and drainage system may be a source of national danger, to correct this condition. That the Ottawa authorities did not realize the far-reaching power of their epidemics, is shown by the fact that they permitted their plan for the annual exhibition, held at Ottawa, to be carried out, drawing thousands to that city, at a time when new cases of typhoid were still being reported.

I am told that the experience through which Ottawa has just passed could be repeated at Montreal; that the relation of water supply to sewage is such that a contamination as it occurred at Ottawa might take place at any time at Montreal. If the National Government were responsible for the water supply and sewage, as it is for quarantine stations, coast defences, light houses and harbors, it would be possible to institute uniform measures approved by the highest authorities. Until some such plan is adopted, this question of vital importance will be at the mercy of political manipulation and the ignorance of half-trained officials.

As stated at the beginning of this article, these opinions are expressed with regard to typhoid fever in general. I do not wish to convey the impression, that what has been witnessed in the state of affairs prevalent in Ottawa is peculiar to that city; the menace lurks, under our present health regulations, in many large towns throughout the continent. The grave-yards of Philadelphia and Baltimore are filled with the silent victims of municipal ignorance or political corruption. What, I trust, has been shown is that a typhoid fever outbreak of the proportion of that in Ottawa, is a subject for widespread concern. It calls for the most serious consideration of the present health regulations, which make possible so appalling a destruction of life and health in an otherwise fair city.

Is it possible to allow longer so subtle and hideous a national enemy to be met only by local health officers whose training may be inferior and whose appointment may have been the price of some political favor? Why cannot our health officers, like our military and naval officers, be removed from petty political influences? Why should not this continent benefit in its maintenance of health by the highest scientific ability? Why should commerce receive more adequate protection than public health? Finally, Ottawa's epidemics, and all outbreaks of like proportion, must remain in their consequences a national and international menace for years to come.

NEW BRUNSWICK'S LUMBER INDUSTRY

The opening weeks of the new year have brought indications of a progressive movement for 1913 The managing director of the Atlantic Sugar Refineries, Limited, visited St. John with other officers of the company to arrange for immediate work on the foundation of the sugar refinery The foundation work will be done by an American concern. There will be a group of seven buildings.

The announcement is made that the plans of the Grand Falls Company for the development of electrical power on a large scale, and the erection of a large pulp mill at Grand Falls, are being prepared.

At Taylor Village, near Dorchester, a crew of men are at work prospecting for manganese, and the indications are favorable.

A landscape architect has arrived at St. John from Montreal to plan a model workingman's village for the employees of the Maritime Motor Car Company, three miles from the city.

The St. John Valley Railway Company have given orders for a sufficient quantity of 80-pound rails to lay 120 miles between Gagetown and Centreville, passing through the city of Fredericton. These rails are to be delivered in June and July, and it is expected that this portion of the line will be nearly finished this year.

The Canadian Pacific Railway Company will increase its accommodation for cars on its property at the head of St. John Harbor, where last year it laid extensive tracks and built warehouses.

A member of a large lumber concern in Boston was in the city last week placing orders, and states that he expects to buy 12,000,000 feet of New Brunswick lumber. Speaking for the lumber interests of the United States, he said they did not look for any change in the lumber tariff and did not want any.

There have been notable increases in the last year in the quantity of spruce shipped from Northern New Brunswick to Montreal, and a number of cities in Ontario, Toronto included. This market has been of great value at a time when ocean freights for lumber were practically prohibitive.

The present winter has been almost the mildest on record, and quite the worst for lumbering operations in the history of the trade. There has been more water in the swamps, and the absence of snow has greatly impeded work, and the cut of logs will, therefore, be very much smaller than usual.

The Dominion Coal Company made plans last year for the extension of their plant for handling coal at St. John. It is stated that this work will be carried out this year.

Norton Griffiths Company, Limited, are asking some financial concessions from the city and province with a view to making the new drydock 1,150 feet long instead of 900 feet, and offer in return to reclaim a site for steel works and shipbuilding plant, and to bring about the establishment of these industries.

AT NIAGARA FALLS.

The year 1912 was a good one at Niagara Falls, Ont. Possibly $300,000 worth of residential building and fully $600,000 of factory buildings, mostly additions to present factories, were erected. Six new industries were located there during the year, and prospects for 1913 are exceptionally bright. In addition, the three great power development companies operating there have expended many millions in increasing their plants.

The Excelsior Brick Company has increased the amount of its capital stock from $150,000 to $250,000, such increase consisting of 1,000 shares of new stock of $100 each.

A MODERN STEEL MILL BUILDING.

One of the largest and most up to date mill buildings in Northern New York was built this season for the Bagley and Sewall Company, of Watertown. This firm is one of the foremost manufacturers of paper making machinery in the world, and their business has increased so rapidly that very frequent additions to the plant have been necessary.

In a recent issue of the Cornell Civil Engineer, Mr. A. W. Harrington, has an article describing the construction of this building. The following is abstracted from the article.

The structure in question is 420 feet x 120 feet in size with a small wing 120 feet x 30 feet. The frame is entirely of steel and the walls concrete, and plaster on Hy Rib. The main structure is carried by the outside 8 inch and 10 inch wall columns and by two rows of 20-inch columns running the length of the building and providing a crane run of 60 feet span, in which operates a Niles fifteen ton electric crane.

A mezzanine floor, for light machinery, 30 feet wide, runs down the north side and across the east end of the building. The south bay, also 30 feet wide, comprises a crane run for a Niles ten ton electric crane.

In the future, finished work can be loaded for shipment directly on the cars, two branch tracks entering the building from the west end, and being served by the 15-ton and 10-ton cranes respectively.

Excavation for the boiler room and coal pocket was begun in January, and some 2,000 yards of rock were taken out and crushed for use on the work. The first concrete was put in the walls of the coal pocket early in March while the weather was still cold. To prevent freezing the water was heated and 5 per cent. of salt added, it not being entirely convenient to heat the sand and crushed stone.

The foundations for the side walls and the piers for the centre columns were next put in. The footings for the side walls were 20 inches wide on top and varied in depth from two to twenty feet, being carried to rock in all cases. The centre piers were 30 inches square. The base plates of all columns were drilled for two anchor bolts, and these bolts were put in when the walls and piers were built. The forms were strongly braced to line and the tops cut off to the floor level and then wooden templets were set to hold the anchor bolts in place while concreting was progressing. It was necessary to locate the anchor bolts very carefully, owing to the large number of columns and the very considerable length of the building, for this purpose a straight edge, or templet was made, in each end of which were two holes, to correspond to the two bolts, and the distance between the two pairs of holes was laid off very carefully. The templets on the forms were laid off with this straight edge and lined in with a transit. In this way the anchor bolts were spaced correctly and uniformly, which might not under all conditions be possible with a steel tape.

As fast as the steel arrived, it was unloaded directly from the cars with a small derrick, and as soon as sufficient steel was on the ground, erection was begun at the east end. A traveler with an 85 foot boom was used, and it was possible with this equipment to reach the entire width of the building and put up the full section of the work at once.

The cost of erection of the 600 odd tons of steel ran about $8.00 per ton. A small air compressor, supplied with steam from the hoisting engine, delivered air for two riveting hammers. Two gangs drove on an average about 275 rivets each per day, and the 12,000 or more rivets cost in place around eleven cents each. The riveters were followed by the painter, and the contract price for this work was 60 cents per ton, a rather high figure for this class of work.

The Detroit Fenestra steel sash was attached directly to the steel window framing. Practically the whole elevation of the building on all four sides is steel sash, and in addition, a row of monitor sash on either side of the main roof furnished light from above.

The next step was the putting up of the Hy Rib for the walls. All walls above the sill of the lower windows were of plaster on this material. The Hy Rib was attached to the window framing and steel work by wire and the standard clips. The cost of the work was high, inasmuch as it was in such small detached pieces, owing to the closeness of the windows, etc.

The plaster on the Hy Rib was about a two to one mixture, and the finished wall was generally about 2½ inches thick. The labor cost of putting this on figured about $1.00 per square yard, exclusive of material. This sort of thing for outside walls is something new in this part of the state, where the winters are very severe, and it is somewhat of a question how this thin wall will compare with brick or concrete of ordinary section as a non-conductor.

Heavy ribbed glass was used on all windows, there being some 20,000 square feet of surface.

While this work was progressing the roofs were being put on, 3 inch x 6 inch nailing strips were fastened directly to the trusses and roof beams with lag screws, and a 2-inch southern pine roof laid on the strips. A Barrett Specification 5 ply roof was then put on. The roof water is carried by gutters to frequent down spouts, by which it is conducted into several drains which lead directly to the river.

Foundations for all the heavy machines were put in as soon as the frame was up. These were invariably of concrete and carried to rock.

The main floor consists of a 6 inch concrete base, with a 2-inch hardwood floor laid on 4-inch x 4-inch treated nailing strips embedded in the concrete.

The larger doors are all Kinnear rolling doors of suitable type.

The building is to be heated by steam furnished by one 200 H.P. and one 50 H.P. boiler. All power is electric, and is furnished from the company's power plant near by.

The cost of the building, exclusive of any equipment, was about $100,000. The work was done by force account, except the steel work and the heating. The structural steel was designed and erected by the National Structural Company of Syracuse.

TESTS OF ROOF BEAMS.

Physical and chemical tests have been made by Messrs. Robert W. Hunt and Company for the investigating committee of the City Council of one of the two collapsed I-beams in the roof of the Home Theatre building, Chicago, the failure of which was reported in the Engineering Record on December 21, page 682. A 4 x 20-in. specimen of steel was cut from the web of one of the ruptured 24-in. I-beams, 8 in. from one end and 3½ in. from the top of the flange. The specimen was machined into a standard-shaped test piece, the central 9-in. portion of which had cross-section dimensions of 1.535 x 0.474 in. After fracture this section was 1.141 x 0.307 in., giving 51.86 per cent. reduction in area. The elongation in 8 in. was 2.22 in., equivalent to 27.75 per cent., and the character of the fracture is described as silky. Under a 180-deg. cold flat-bend test the report states the specimen is "O.K." The elastic limit was 39,240 lb. per square inch and the tensile strength 59,180 lb. per square inch. Chemically, the analysis of the drillings is given in percentages as follows: Carbon by combustion, 0.098; phosphorus, 0.109; manganese, 0.49; sulphur, 0.126; silicon, 0.01.

MONTREAL TRAMWAYS AND SUBSIDIARY COMPANIES

Matters in connection with the Montreal Tramways and Power Company and its subsidiaries are occupying almost the entire attention of financial circles in Montreal and the citizens generally. The Monetary Times last week reviewed the case of Messrs. Ernest E. Vipond and Herbert S. Vipond against the Corporation Agencies, Limited, and H. A. Lovett, K.C. Plaintiffs were suing for $279,500 which they claimed was the value of the rights and franchises of the Montreal Hydro-Electric Company, which had been turned over to the Montreal Tramways and Power Company by defendant, the Montreal Hydro-Electric Company being a holding company or merger formed by Mr. Lovett of two concerns of which the Viponds were apparently the principal owners. They were the entire owners of the Montreal Electric and, they alleged, were the owners of an option on the other company, the Electric Power Company of Montreal, which, Mr. Lovett, in the direction of carrying out his contract to carry the scheme through to an operating basis, had merged into the Montreal Hydro-Electric. This was in 1911.

The Viponds claimed that defendants had not fulfilled their contract in the manner in which it was made but had turned the Hydro-Electric into the Montreal Tramways and Power which was the big concern formed to take in the Canadian Light and Power, the Tramways Company and a number of other smaller power concerns of the city. Their particular objection seemed to be to the inclusion of the Canadian Light and Power in the Tramways and Power Company.

In this connection, came up the name of the Imperial Trust Company, which had officiated in the transfer of the Hydro-Electric to the Tramways and Power Company. It was shown that it was under the same control as the Canadian Light and Power, the Tramways Company, and the Tramways and Power Company. Further connection was attempted by showing that Mr. H. A. Lovett, K.C., was closely associated with this group of companies also, as their counsel. Then was made an attempt to have certain documents relating to the deal produced by the Imperial Trust Company. Argument on this point went on for some hours and resulted in the Judge ordering the production of the documents. The official claimed he would have to consult those in authority first, upon which the Judge read him a lecture and ordered the documents to be produced.

At this juncture the counsel for the defence announced that under such circumstances he would beg to take the matter to the Court of Appeal. The matter will accordingly be brought before the Appeal next month.

Meantime, the Canadian Light and Power Company has sustained an attack from another direction, certain large contractors having entered suits for amounts aggregating, it is claimed, nearly half a million, on the grounds that contracts completed at the company's plant near Valleyfield had never been paid for and that their engineers had been prevented from making the final estimates necessary to secure the balance of payments due

During the past week, also, the appeal of the Tramways Company on the grounds of jurisdiction was made against the Public Utilities Commission of the province of Quebec. The arguments put forward were much the same as those outlined at Quebec recently, when the company was ordered to appear and show grounds why the Commission should not take other means to obtain the details of information previously ordered, and at the expense of the company. The burden of the appeal was that the government of the province had relieved the company of the jurisdiction of the control of the Commission. The lawyers who were to present the arguments to the contrary were not ready, so that the matter will be heard later.

OUR PIG IRON MADE FROM NEWFOUNDLAND ORE

Some interesting evidence concerning the demand for and supply of iron ore was given before a meeting of the Dominion Royal Commission held in England last year, by Mr. Wallace Thorneycroft. It was stated that most of the ore imported into Great Britain was made into Bessemer hematite pig-iron, which was used for steel making by the acid process. For that purpose the ore must contain very little phosphorus. Great Britain imported in the year 1909, 6,326,000 tons of iron ore, of which nearly 6,000,000 tons was Bessemer ore.

Nearly 5,000,000 tons of this Bessemer ore came from Spain, and the balance from Sweden, Norway, Greece, France, Algeria and Tunis. Except 62,000 tons from Newfoundland, no ore was imported during that period from the Dominions. Cumberland and North Lancashire supplied 1,558,000 tons of Bessemer ore. Therefore the Bessemer pig-iron industry depended upon foreign ore supplies.

It was probable that the deposits of Bessemer ore in Spain would be approaching exhaustion 25 years hence. It was also probable that supplies of this quality of ore would be got from other countries, but at an increased cost of freight. There were large known deposits in Brazil, Cuba, Chili and Venezuela, some of which were being developed.

The Wabana deposit in Newfoundland, from which the bulk of Canada's production of pig-iron was made, was said to contain over 3,000 million tons of ore. But as it contained .75 of phosphorus it was unsuitable for the manufacture of steel by the acid process. It was largely exported to Germany and Belgium, where steel was manufactured by the basic process, by which the phosphorus was extracted from the steel.

Basic steel, it was stated, was not as reliable as steel, manufactured by the acid process from Bessemer ore containing less than 0.5 of phosphorus. If the basic principle were adopted in this country there would be a greater demand for Newfoundland ore. The more rapid growth of the pig-iron industry in Germany and the United States was, it was said, entirely due to the invention of the basic process.

Except in Canada there was, so far as is known, no production of pig-iron on a large scale in the Dominions. The governments of the Dominions, it was stated, might, with advantage, provide more money for the geological survey of the territory under their control. There could be no more profitable investment. They should publish the results of the surveys made as rapidly as possible, and communicate advance copies to the iron and steel associations of this country, or abstracts and references to such publications.

It was not suggested that the governments should undertake detailed prospecting work. The geological department of Canada was already very good, but with the vast area it had to cover, progress was necessarily slow.

The indication of large deposits, especially Bessemer ore, accessible for shipment anywhere in eastern Canada or Newfoundland would promptly be investigated in detail by British makers of iron and steel and ample capital would soon be found if the deposits warranted development.

It would be right for the Dominion governments to encourage the export of iron ore. If the economic conditions around the deposits were favorable, production of pig iron and steel would naturally follow.

"Structural Details of Hip and Valley Rafters." By Carlton Thomas Bishop, C.E., assistant professor of civil engineering, Sheffield Scientific School of Yale University, formerly draftsman for the American Bridge Co., and chief draftsman for the Hay Foundry and Iron Works. Published by John Wiley and Sons, New York; Canadian agents, Renouf and Co., Montreal. Oblong, quarto, fully illustrated by general drawings and typical problems; v. + 72 pages. Cloth; $1.75 net (7/6 net).

Reviewed by J. Roy Cockburn, B.A.Sc.*

This book presents the subject of hip and valley construction very clearly and in a very convenient form for reference. It is evidently intended more as a handbook for structural draftsmen than as a text book for students although it should serve admirably as either.

All notes are conveniently arranged and completely illustrated by general drawings and typical problems. The complete derivation of every complicated formula is given in full and can easily be followed by anyone familiar with structural detail, plane trigonometry and the elements of descriptive geometry.

The book is devoted almost entirely to the solution of problems relating to the connections of purlines to hip and valley rafters. Both flange and web connections are taken up and examples worked out for buildings intersecting at various angles. The graphical as well as the analytical solutions being given for the various cases.

Although the book is well written and accurate in nearly every detail there are a few points which are open to criticism namely, in fig. 1. on page 1, the term "elevation" is used to describe a view which is of the nature of a perspective. On pages 8, 10, 30, and 32 we find

formula (30) $\tan. C = \dfrac{b' \sin. L}{b'' + b' \cos. L}$ when L is less than 90°

and formula (31) $\tan. C = \dfrac{b' \sin. L}{b'' - b' \cos. L}$ when L is greater than 90°.

Formula (30) is correct for all values of L, the quantity (b' cos. L) becoming negative when cos. L becomes negative. Formula 31 is not only superfluous but wrong. Again on page 2 we read that all formulas have been arranged so that they involve the use of only three functions of any angle, namely, the sine cosine and tangent; which is quite desirable. We also learn from the notation given on page 3 that w' = the largest of the angles between the line of bend and the centre line of the top flange of the hip or valley rafter (steeper roof), and that z' = the tangent of the angle between the purline of the steeper roof and the hip or valley rafter in the plane of the roof. It should, therefore, follow that w″ and z″ would equal the tangents of the corresponding angles referring to the flatter roof, but in formula 26, pages 4 and 6, formula 67 pages, 26 and 28, and formula 73, pages 30 and 32, w″ and z″ are taken to represent the cotangents of these angles. The reason for such a change being given in a footnote which reads as follows:—

"If any of these values exceeds 1'—0″ the level should be reversed or the drawing so that the longer side becomes the 12″ base and the shorter side the reciprocal of the value found." This reciprocal is obtained directly from the cologarithm. Care should be taken, however, that the original values are used in all further calculations.

The book should prove of great service to all who are interested in the class of work which it treats.

"Sewage Disposal in the United Kingdom." By Henry Lemmoin-Cannon, published by The St. Bride's Press, Limited, Fleet Street, E.C. Cloth; 8 x 5½ ins.; 320 pages, 52 cuts. Price $2.

Reviewed by T. Aird Murray.*

This treatise forms a compact text-book illustrating and explanatory of methods of sewage disposal as practised in Great Britain. The information as far as methods of sewage disposal are concerned, practically brings and leaves the reader in line with the conclusions and data produced in the fifth report of the Royal Commission. There is in brief much useful information of a legal and routine nature useful to the British engineer in preparing schemes which in accordance with British law must be submitted to and receive the sanction of the Local Government Board in London. This information concisely put should be of value to Canadian authorities in guiding and formulating regulations for the control of similar schemes here.

To the Canadian engineer the information to be obtained is more of historical than actual value, salient points which have awakened much interest on this side are not dealt with. We refer to problems of treatment of sedimented sludge by separator tanks. The engineer who is looking for

*Consulting engineer, 303 Lumsden Building, Toronto.

information on many of the more modern problems connected with sewage disposal will find the information very incomplete. On the other hand, the student who wishes to become familiar with the history of sewage disposal leading up from the older methods of land treatment to the more modern methods of biological treatment, will find crystallized in one volume a very large amount of useful information difficult to obtain so readily elsewhere. Perhaps the most disappointing feature in connection with recent English publications on sewage disposal is the monotony of sameness with which they are characterized. No sooner do we open a so-called up-to-date English publication on this question than we feel that we have seen the book before; page after page contain wholesale extracts from the almost out-of-date fifth report of the Royal Commission, and our eyes are met with the same old and familiar illustrative cuts gleaned from manufacturers' catalogues which are becoming familiar to Canadian engineers by the recent spread of catalogues throughout the Dominion. What we feel we would like to see on this side would be some concise work fearlessly written, disclosing and illustrating the many failures which must have accompanied the installation of so many varied types of sewage disposal systems in Great Britain. Such a work would be useful in a new country, so that past errors may be taken advantage of in designing new works.

"Modern Destructor Practice." By W. F. Goodrich. Published by Charles Griffin and Co., Exeter Street, Strand, London. Cloth, size 6 x 8¾ ins.; 278 pages, 116 illustrations. Price $4.

Reviewed by R. R. Knight.*

Well arranged, full of information, and replete with data of existing practice, this book commends itself to the municipal engineer.

The author leaves no doubt in the mind of the reader as to his conclusions which are clearly stated and well worth consideration. He discusses the type of furnace, and it is clear that the cellular type has had to give way to the continuous grate furnace. Shovel fed furnaces are advocated, while at the same time mechanical and top feed furnaces come in for consideration. It should be noted, however, that a mechanical feeding apparatus is being "tried out" now and any conclusion should be deferred until the results are known. Destructor engineers will generally agree with the author that the full load charge has proved a failure, and that some means of steady and intelligent feeding with some modification of the littered platform is required, either mechanical or otherwise.

In the chapter devoted to Refuse Destructors combined with Sewage Works, the question of power production only is treated with. The views of the author with data as to sludge burning would have been welcome.

The photographs showing proximity of dwellings, etc., to destructors are interesting, and have a value as arguments in many cases.

Under the title "Specifications," a lot of information is given, and should prove useful in providing a reasonable base for tendering. The author does not commit himself as to cavity walls. In the matter of cast iron skewbacks I can give hearty support. Water seals, the author considers undesirable. With this statement many will disagree. The water seal has proved itself an efficient, flexible joint invaluable where, as in the case of furnace castings and steelwork, there is so much warping and twisting.

Mechanical clinkering is mentioned. It is early yet, however, to make any definite statement regarding the efficiency of this adjunct.

*Main Drainage Department, city of Toronto.

The most important feature of this work is the author's views on the question of garbage reduction. Mr. Goodrich has done what a great many destructor advocates have done, and must do in the face of facts, viz., admit that reduction is established as a paying process and can be carried out in a sanitary manner.

The author, in spite of his previous condemnation of the process (mainly due to the operation of plants for gain) says "there are signs that reduction will be undertaken by municipal authorities to some considerable extent during the next few years. He adds that from personal observation (speaking of Columbus, Ohio), the works are free from those objections which have been the subject of continual complaint with regard to garbage reduction works generally. This admission is important coming as it does from such an eminent source.

"Steam Boilers." By E. M. Shealy, assistant professor of steam engineering, University of Wisconsin. Cloth, size 6 x 9 ins., 366 pages. MrGraw-Hill Book Co. Price $2.50 net.

Reviewed by R. W. Angus, B.A.Sc.*

This book forms the fourth volume of the series published for the Extension Division of the University of Wisconsin, and in the introduction the author states that it "was written primarily for correspondence students, and is intended for the use of firemen and others who may be in responsible charge of boiler rooms." Having this in mind formulas have only been introduced into the book to a limited extent and much descriptive matter has been inserted.

The first two chapters are devoted to a complete description and classification of various types of boilers in use, along with the setting in each case, and in most cases a brief discussion of the merits of the given type. The description is well illustrated and should be helpful in acquainting the reader with the great variety of boilers in use. One might naturally expect the chapter on stays, which is purely descriptive and explains the purpose, construction and use of stays, manholes, etc., to follow the general description, although no reasonable objection can be made to separating this from the other chapters by a few calculations.

The author has purposely avoided dealing with boiler design and yet has given some formulas, illustrated by numerical examples, which show how the thickness of the shell may be determined. Such calculations cannot help but be of assistance, and yet they are a little apt to be misleading unless the form of joint is discussed, as the latter is one of the leading factors in determining the thickness of the shell. The computation of the heating surface of a boiler, illustrated by a numerical example, worked out in a simple way, is of much value to the class of reader sought and the method employed should be very readily understood.

The next few chapters deal with the relation between heat and work and the effects of heat, and numerical illustrations are given in some cases. The work on the properties of steam, etc., is given in some detail to enable the reader to know the value of the various conditions of steam. This matter is at best rather difficult, but the writer seems to have treated it in as simple a form as possible and gives a table of the properties of saturated steam which may be made use of in solving problems.

While several pages have been devoted to factors of evaporation, etc., the boiler horsepower has been passed over in two paragraphs, which seems rather unfortunate, as it would give a very useful application of the steam tables, and after all the boiler horsepower is one of the primary ob-

*Professor of Mechanical Engineering, University of Toronto, Toronto.

jects of all tests and is very largely a measure of the value of the boiler. The author has devoted considerable space to this matter in a later chapter.

Some considerable attention has been given to fuels, their combustion and the methods of firing and of setting boilers, all of which are important.

The book further contains chapters on boiler accessories, chimneys and draft (in which the dimensions and construction of chimneys are studied), boiler feed waters, feed water heaters, inspection and care of boilers and on boiler testing. All of the chapters are well illustrated with cuts and contain some numerical examples.

On the whole the volume has been written with much care and gives a treatment of this subject that should appeal to a man with a sufficient technical knowledge to understand simple formulas.

"Design of Electrical Machinery." A treatise for the use, primarily, of students in electrical engineering courses. Vol. III., "Alternators, Synchronous Motors, Rotary Converters," by William T. Ryan, E.E., assistant professor of electrical engineering, the University of Minnesota. (Vols. I. and II. treat respectively of D.C. machinery and A.C. transformers). Published by John Wiley and Sons, New York; Canadian agents, Renouf Publishing Company, Montreal. Cloth. Price $1.50 net.

Reviewed by J. A. Johnston.*

The rapid increase in the mass of engineering knowledge, with its resulting demand for highly specialized engineers is fast creating the serious problem of how to present to the student within the available time, all of the fundamental information which he ought to have. Any work, therefore, which succeeds in concentrating into small compass the fundamentals of any particular branch of engineering is a step in advance in the solution of this problem. The volume above named is such a work. It presents in four well-ordered chapters, covering 122 pages, such fundamental principles and knowledge of the design of alternating current apparatus as should be possessed by every electrical engineering graduate. While the material presented is sufficient, with a pre-supposed knowledge of first principles, to enable operative designs to be made and is largely drawn from commercial designs, it makes no attempt, as is proper, to present all the kinks of commercial practice. The physical get up of the book is fully up to the standard of its publishers and leaves little to be desired. It is profusely illustrated.

"Modern Road Construction"—A Practical Treatise for the Use of Engineers, Students, Members of Local Authorities, etc. By Francis Wood, M. Inst. C.E., F.G.S., Borough Surveyor of Fulham, England. London: Charles Griffin & Co., Ltd. Cloth; 5¼ x 8 in.; 137 pages; two folding plates and 25 text figures. $1.50 net.

This volume, in a concise and not too technical form, gives the general characteristics and details of roads gathered from the author's experience in road construction. The book opens with a general introduction and a discussion of the effect of traffic on different types of roads, while the greater part of the remainder of the volume is devoted to bituminous construction.

This discussion is made up principally of notes taken by the author on road construction, repair and maintenance over quite a period of years, and as the notes are largely a result of his own practical experience and observation, the highway engineer will find them of considerable value. The author goes into considerable detail in describing bitumen and its application to road construction, not only as a blanket treatment, but also when incorporated in the road surface. Several pages are devoted to tests and analyses of bitumen and to comparisons of the results obtained by the use of different kinds of bitumens in road construction. A few pages are devoted to costs, but the cost data in the book can hardly be utilized by engineers in this country, as insufficient data are given of the rate paid per hour for labor and of the cost of material.

In the appendices are given typical specifications for constructing streets of macadam and wood pavement, and the specifications of the road board of England for surface tarring, and surfacing with pitch-grouted macadam, also extracts from the road board's specifications for tar and pitch. The book is well indexed, and is very clearly worded, making it interesting and very convenient for reference.

"Engineering of Shops and Factories." By Henry Grattan Tyrrell, C.E.; author of "Mill Buildings," "Concrete Bridges and Culverts," "History of Bridge Engineering," "Artistic Bridge Design," etc. New York: McGraw-Hill Book Co. Cloth, 6 x 9 ins., pp. xvii. + 399; 175 illustrations. $4 net.

Reviewed by C. R. Young, B.A.Sc.*

In this, his latest, book the author has gathered together a large amount of information of great value to those who have to do, in a responsible capacity, with the planning of shops, factories and industrial buildings of all classes. The subject matter is sufficiently comprehensive to interest at once the manager and the engineer, and yet possesses enough of definiteness and detail to be of considerable value to the engineer in a technical sense. Certain matters which have been treated fully in the author's "Mill Buildings" are briefly discussed in the present work but the larger part of the information presented is supplementary to that contained in the former book.

An examination of the contents reveals an opening chapter which will meet with the hearty approval of engineers and architects at least. It is a frank discussion of the various arrangements by which owners manage to secure plans, specifications and engineering services for the construction of their buildings. The fallacy of "free" engineering is exposed and a plea which ought to be convincing to any reasonable proprietor is made for the employment of expert engineers in accordance with the terms recommended by the great engineering societies.

Proceeding with his subject, the author lays down the principles governing the selection of a manufacturing site, and then discusses at somewhat greater length the "Economies of Factory Construction." Eleven different matters affecting the design of the plant, and on which the engineer should be thoroughly informed, are cited and discussed in order. Illustrative of preliminary designs and reports, the author inserts a report of his own covering the establishment of a proposed structural plant. Data affecting general design, such as æsthetic treatment, wind pressure, loads, stresses, specifications, then receive brief consideration, followed by a short chapter on the "Selection of Building Type." Material of considerable value to the engineer or architect then follows in a 63-page discussion of wood, metal and concrete framing. The production of a pleasing finish in concrete structures is given full attention in an excellent chapter on "Concrete Surface Finish." Then follow chap-

ters on "Costs of Buildings," "Foundations," "Ground Floors," "Upper Floors," "Walls, Partitions and Openings" "Roofs and Roofing," "Notes on Special Buildings," "Storage Pockets and Hoisting Towers," "Factory Heating," "Air Washing Systems," "Factory Lighting," "Drainage of Industrial Works," "Water Supply and Storage Tanks," "Steel Chimneys," "Fire Protection," "Cranes," "Yards and Transportation," "Estimating," "Construction," "Welfare Features," and "Standard Buildings." A useful bibliography of the subject of industrial plants is given at the end of the book.

The book is in every way a commendable addition to the literature of industrial plant design and should be in the hands of all those responsible for such work.

Fire Prevention and Fire Protection, as Applied to Building Construction. A handbook of Theory and practice. by Joseph Kendall Freitag, B.S., C.E. Published by John Wiley & Sons, New York, and Chapman & Hall, London. 1,038 pages; 4½ x 7 inches; 395 illustrations; Morocco, $4.00 net.

Reviewed by C. H. C. Wright.

This is a very timely handbook for the architectural profession and others interested in the text. It contains a very large amount of useful information sufficiently condensed as to be serviceable without being so brief as to leave the reader in doubt. The whole book is written in a descriptive manner which will make it interesting reading, and has been divided into six parts, viz.: I., Fire Prevention and Fire Protection; II., Fire Tests and Materials; III., Fire-Resisting Design; IV., Fire-Resisting Construction; V., Special Structures and Features, and VI., Auxiliary Equipment and Safeguards.

These parts have been further divided into chapters, each of which has been well studied with reference to the others, so that it is comparatively easy to find information on any matter connected with this broad subject. For example, Chapter III. of Part I. treats very thoroughly and clearly, as a handbook on this subject should, of "The Theory and Practice of Fire Insurance," and is of itself worth the price of the handbook. The chapter immediately following on "Slow-Burning or Mill Construction" is worthy of mention.

Chapter VII. in Part II., "The Materials of Fire-Resisting Construction," contains much useful information compiled as it is from a multitude of reports, laboratory tests, fire tests and conflagration tests, showing the behavior of many building materials. A few quotations which will show the attitude of the author might not be out of place here.

"No material with which we are at present acquainted, at least to any commercial extent, is fireproof." "The word 'fireproof' rather describes an ideal condition yet to be obtained." "Hence, in view of the misconception attached to the term 'fireproof' the word has been discarded for the more rational one 'fire-resisting.'"

"The efficiency of fire-resisting construction depends largely upon (1) The choice of materials; (2) The materials used for insulating or protecting those load-bearing members which, of necessity, are not fire-resisting; and (3) The limitation as far as may be possible of combustible finish or trim."

On the much debated question of structural terra-cotta or concrete, the author says (page 235): "No other materials employed in the fire-resisting construction have exhibited such seemingly contradictory testimony as to their fire-resisting qualities as have structural terra-cotta and concrete. Arguments and examples for or against tile and concrete could easily fill a volume of large size. If one has any preconceived bias in favor of either, it is not difficult to find, from recorded opinions and experiences, data sustaining such preferences." After some seventeen pages of condensed information the author concludes with the following (page 252): "The writer believes that there is no decided choice between good concrete and good structural terra-cotta construction."

Under the heading of "Permanency and Corrosion" is tabulated the information obtained from the delapidation of a number of buildings such at the Bank of the State of New York, built in 1855; the Mutual Life Building, San Francisco, 1893; the Gillender Building, New York, 1896, etc.

Among the opening remarks of Part II., on Fire-Resisting Design, is the following: "The question goes deeper than this, for the vital fire-resisting qualities must be inherent in the design, and cared for as naturally as are commercial aspects. A building intended to resist fire may be likened to a position intended to resist attack. The works to be defended must first be well chosen as to position, and substantially and scientifically designed; second, well carried out in all details at crucial points; and lastly, manned by an effective garrison or force."

The conclusions drawn from experience with regard to the many features in planning are very clear and forceful; e.g., no fire drill could be of assistance in a single loft building in New York City, and the only thing left for the occupants of any such building is to jump or be burned to death, as was the case at the Asch Building, (the Triangle Waist fire).

Much could be said of the following chapter on "Efficiency vs. Faulty Construction," as well as of many of those which follow, but space forbids anything more than to say that Part V. treats of the subject under the headings: Theatres, Schools, Residences, etc., and Part VI. of Sprinklers, Alarm Systems, Watchmen, etc.

The question of relative costs is fully dealt with in every case throughout the book and forms a most valuable feature of it.

This book will prove a great stimulus to the scientific and systematic study of fire prevention and fire protection.

"Canadian Almanac." Published by the Copp, Clark Company, Toronto. Cloth, 6 x 9 ins.; 520 pages.

This volume, brought out by the Copp, Clark Company, has been published continuously since 1848, and its usefulness increases each year. It contains, among other things, astronomical calculations, the complete customs tariff, a full list of Canadian post-offices, and information as to postal rates, militia list, names of all clergymen and lawyers, of members of the Dominion and Provincial Governments and chief officials, county and township officers, newspapers, educational institutions, Canadian amateur athletic records, and a splendid series of maps.

CATALOGUES RECEIVED.

Water Wheels, etc. Boving and Company, Limited, Union Court, Old Broad Street, London, E.C.; Canadian office, the Canadian Boving Company, 162 Bay Street, Toronto, forward pamphlet illustrating the different apparatus and machinery manufactured by them.

Everything for Blue-Printing. The C. F. Pease Company, 166 West Adams St., Chicago, forward catalogue illustrating their different machines for blue-printing.

Lock Metal Forms. The Hotchkiss Lock Metal Form Company, Binghamton, N.Y., forward catalogue illustrating their steel forms for walks, curbs and gutters, wall forms, etc.

Garbage Disposal Plants. The C. O. Bartlett and Snow Company, Cleveland, Ohio, forward their catalogue, No. 29, illustrating different garbage disposal plants installed by them.

Hydraulic Machinery for Rubber Mills. R. D. Wood and Co., 400 Chestnut Street, Philadelphia, Pa., forward their catalogue, No. 7, showing special hydraulic machinery made by them for the manufacturing of celluloid and rubber goods.

Block Sheaves and Wire Rope. The Clyde Iron Works, Duluth, Minn., forward a handsome little catalogue illustrating their different types of block sheaves and wire rope.

Sewage Disposal. Jones and Attwood, Limited, Stourbridge, England, forward catalogue illustrating different types of installations of their apparatus for the sewage disposal of country houses and institutions.

"Lever Punches and Shears," a 40-page catalogue, has just been published by the Watson-Stillman Company, 50 Church Street, New York. Many types are illustrated and tabulated. Free copy mailed on request.

Water Filtration. The New York Continental Jewel Filtration Co., New York, the designers of the Filtration equipment for the East Jersey Water Company, Little Falls, N.J., forward a very complete description of the plant, together with table showing the average result obtained from the filter.

"Ruggles-Coles Road Machines" is the title of a 12-page pamphlet just issued by the Ruggles-Coles Engineering Co., 50 Church Street, New York, and the McCormick Building, Chicago. It contains information with illustrations of the Ruggles-Coles portable and semi-portable drying and heating plants for bituminous concrete work, and also describes the new Ruggles complete drying, heating and mixing plant outfit for road work. The pamphlet will be sent on request to any of the Ruggles-Coles offices.

Bulletin No. 105 Lackawanna Steel Sheet Piling has just been published by the Lackawanna Steel Company, Lackawanna, N.Y. This 28 page, 8 in. by 10½ in. bulletin shows in a clear and concise way the reasons for and values of the three principal types of Lackawanna steel sheet piling straight-web sections, such as were used in the raising of the "Maine," are used for ordinary work where the principal forces to be resisted are tensile or where the water-tightness is essential. Arched-web sections are of value where the piling must resist transverse bending forces, as in foundation pits. Steel piling protected by concrete, a new piling just put on the market by this company, is used for permanent levee constructions, revetments, etc. Illustrations in this bulletin show the piling in the act of being driven, braced, cut by the oxy-acetylene process, etc. A free copy will be mailed on request.

"Scale Removal from Condensers," is the title of an attractive catalogue recently issued by the Lagonda Mfg. Co., of Springfield, Ohio. This book is more than a catalogue, as it contains a very interesting discussion showing the harmful effects of scale in condensers, how it decreases vacuum and increases the power of the auxiliaries. Interesting curves are also included showing the increased steam consumption resulting from the accumulation of scale in surface condensers. The removal of scale and other deposits from ammonia condensers, evaporators, etc., is discussed, and a complete line of cleaners illustrated for use in various kinds of condensers. Copies of this catalogue, No. O-1, may be had by addressing the Lagonda Mfg. Co., Springfield, Ohio.

CHANGES IN STAFF OF GRAND TRUNK.

The following changes in the administration of the Grand Trunk Railway System are announced by vice-president H. G. Kelley.

Mr. L. Harold is appointed Superintendent of Transportation of the eastern lines with headquarters at Montreal, and Mr. F. L. C. Bond becomes Division Engineer of the same lines with the same headquarters. Mr. G. Beckingham becomes Superintendent of track of the eastern lines, and Mr. J. H. Johnston Superintendent of bridges and buildings. Mr. J. J. Connolly, Superintendent of the Montreal division, and Mr. R. W. Scott, Superintendent of Montreal terminals. Mr. J. Caldwell succeeds Mr. C. S. Cunningham as Superintendent of the Detroit division and Mr. J. Ehrke is the new head of the Chicago division. Mr. C. S. Ogilvie becomes Assistant Engineer of the Belleville division.

Mr. T. Cushin is appointed Trainmaster of the third district, with headquarters at Richmond, Que., and Mr. R. P. Smallhorn is appointed Freight Agent at Montreal.

COAST TO COAST.

Moose Jaw, Sask.—The Civic Improvement Committee of this city have asked for the following amounts as part of the civic improvement plan for 1913: Light and power, $185,000; fire and buildings, $105,000; sewer and water, $200,000. These amounts will be asked for in the usual by-law procedure.

Montreal, P.Q.—The new bridge over the River St. Lawrence between the Highlands station and Caughnewaga, erected by the Canadian Pacific Railway, is now open and the double tracks are in operation. The double tracking of this bridge has involved the expenditure of three millions of dollars.

Vancouver, B.C.—The British Columbia Transport Company, Limited, will erect a cement plant at Alberni very shortly. A deposit of the raw material has been found in the neighborhood of Port Alberni and if the final tests prove satisfactory the business of manufacturing cement will be started at once.

Winnipeg, Man.—The gross earnings of the Winnipeg Electric Railway Company have nearly doubled in two years, according to the official statement submitted to City Treasurer Thompson by G. A. Henson, secretary of the company. The gross earnings for 1912 for street car business alone amounted to $2,114,947.93. In 1910 the gross earnings were $1,265,874. The increase in two years is $849,073.

Moose Jaw, Sask.—In the recent figures shown of the growth of Western Canada in building permits granted for the year, Moose Jaw figures prominently. The amounts granted to several cities are as follows: Moose Jaw, $15,275,795; Medicine Hat, $2,836,239; Prince Albert, $2,006,925; Lethbridge, $1,358,250. The total for the year has exceeded the $200,000,000 mark, and a gain of almost $60,000,000 has been made.

Calgary, Alta.—The $2,500,000 contract of the Westinghouse, Church, Kerr Company, of New York and Montreal, for the construction of the new Ogden locomotive and car shops for the Canadian Pacific Railway Company is now about 90 per cent. completed. When the plant is working to capacity the pay-roll for wages alone will be from $8,000 to $10,000 per day. The locating of the shops here will swell the population of Calgary by thousands.

Montreal, P.Q.—Engineers and officials of the Montreal Tramways Company have been gathering data for presentation to the city council regarding congestion of down-town street car traffic. It will be impossible to operate cars on several of the streets unless they are enlarged and more loop lines are imperative. The company agreed to lay tracks on every street wide enough to operate their cars, providing they receive permits from the city to do so. Mayor Lavalee favors the appointment of an expert to report the best plan to remove down-town congestion which, so far, has baffled all attempts at solution.

Ottawa, Ont.—The Calgary, Edmonton and Fort McMurray Railway Company are obtaining a charter to build into the Peace River country, a line 2,300 miles in length in all, a regular transcontinental, or at least trans-Edmonton line, and is asking parliament for the right to use steam and electricity as it may see fit. More than that, it is securing the right to develop electricity and to distribute it along the line of its route to municipalities and private parties. This is a striking example that railway builders of to-day are recognizing that electricity is the coming motive power.

PERSONAL.

MR. GEORGE POWELL, deputy city engineer, Toronto, Ont., was offered a position as works commissioner of Prince Albert, Sask., at $6,500 per annum, but has refused the offer.

JOHN D. WATSON, M.Inst.C.E., engineer to the Tame and Rea District Drainage Board, has been engaged to advise the Metropolitan Sewerage Commission of New York on the disposal of the sewage of that city, and has just left for New York.

FRANCIS P. SMITH, M.Am.Soc.C.E., chemical and consulting paving engineer, New York City, on January 21st delivered an illustrated lecture on "Maintenance of Sheet Asphalt Pavements," before the graduate students in Highway Engineering at Columbia University.

PHILLIP P. SHARPLES, manager of the Tarvia Department of the Barrett Manufacturing Company, and Mr. F. S. Hutchinson, manager of the Tarvia Department of the New York office of the company were in Toronto last week, in connection with the Tarvia interests of the Paterson Manufacturing Company.

FRANK P. JONES, general manager of the Canada Cement Company, and president of the Canadian Venezuela Iron Ore Company, has just returned from a two months' absence from Montreal, spent in Venezuela inspecting the company's mines. Mr. Jones stated that there is a big market for their ore in and about Philadelphia. At present the company is shipping 3,000 tons per month, and before the end of the year will be exporting 50,000 per month.

HOWELL T. FISHER, tunnel engineer for the Mount Royal tunnel of the Canadian Northern Railway, was a recent visitor to The Canadian Engineer office. Mr. Fisher is a member of the American Society of Civil Engineers and of the American Institute of Mining Engineers. He got his first engineering training at Lehigh University, South Bethlehem, Pa., which is now presided over by Dr. Henry S. Drinker, who is an acknowledged authority on tunnels. Mr. Fisher has seen service with the Isthmian Canal Commission, the United States Geological Survey, the Denver Water Company, etc. He was also associated with Mr. Stephen P. Brown, the chief engineer of the Mount Royal tunnel, in the construction of the Fourth Avenue subway, Brooklyn, the East River division of the Pennsylvania tunnel, and the Pennsylvania-New York crosstown tunnel.

CANADIAN SOCIETY OF CIVIL ENGINEERS, TORONTO BRANCH.

The annual meeting of the Toronto Branch was held at the Engineers' Club, Thursday evening, January 23rd. The following officers were elected for 1913: Mr. E. A. James, B.A.Sc., was elected chairman for 1913. The other officers are as follows: Secretary-treasurer, A. Garrow; executive committee, P. Kemble, E. T. Brandon, W. A. McLean, and the retiring chairman, T. C. Irving, jun.

MEETING OF THE IDAHO CEDARMEN'S ASSOCIATION.

At the annual meeting of the Idaho Cedarmen's Association, held in Spokane, Tuesday, January 14, 1913, the following officers were elected for the ensuing year: President, H. C. Culver, Sandpoint, Idaho; vice-president, M. P. Flannery, Spokane, Wash.; secretary-treasurer, R. L. Bayne, Spokane, Wash.

W. M. Leavitt and E. A. Lindsley, with the president as member ex-officio, were appointed to be a committee to draft a constitution and by-laws for the association.

TORONTO CIVIC GUILD.

At the annual meeting of the Civic Guild held last week, with Mr. C. H. Mitchell, C.E., presiding, the following officers were elected for 1913:—President, James B O'Brien, K.C.; first vice-president, C. H. Mitchell; second vice-president, Edmund Burke; secretary, R. J. Dilworth; executive committee—John Firstbrook, J. B. Laidlaw, W. Ford Howland, J. H. Gundy, C. B. Lowndes, H. W. Barker, W. E. Harries and A. Frank Wickson; auditors, J. M. McIntosh.

Mr. F. B. Fetherstonhaugh thought the Guild might take up the question of smoke prevention with a view to having legislation passed compelling the Canadian Pacific Railway, Grand Trunk Railway and Canadian Northern Railway to use electric locomotives for shunting purposes within the city limits. As the subject was raised at a late hour, discussion was deferred until the next meeting.

COMING MEETINGS.

ILLINOIS WATER SUPPLY ASSOCIATION.—The Fifth Annual Me g of the Association will be held at the University of Illinois, Campaign-U r Ill., March 11th and 12th, 1913. Secretary, Edward Bartow.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—Annual Meeting will be held on Jan. 28th, 29th, and 30th, 1913, at the Society's new headquarters, 176 Mansfield St., Montreal. Secretary, C. H. McLeod.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.—Annual Meeting will be held March, 3, 4 and 5, 1913, in the Green Room, Congress Hotel and Annex, Chicago, Ill. Secretary, Will P. Blair.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annu Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway, Secretary. Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—P ident, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

CONSTRUCTIONAL FEATURES OF A LARGE REINFORCED-CONCRETE DOME.

BY L. R. W. ALLISON

The Second Church of Christ Scientist, Los Angeles, California, was recently erected on West Adams Street at a cost of $300,000, and is probably the finest edifice of its denomination in the west. The structure, shown in Fig. 2, is of reinforced concrete and occupies a ground area of 100 by 150 feet; it was built by a popular subscription building fund. In form it is the arche-type of a Greek cross, offering in treatment many distinctive constructional and architectural features.

The church auditorium proper, 92 by 106 feet, has no column or gallery obstructions, and is surmounted by a hemispherical reinforced concrete dome (Fig. 1) 70 feet in diameter. The crown of the dome is 75 feet above the floor line, and at part way of its periphery, thirty-one stained glass sash are placed to afford an upper source of light.

Dome Support.—The supporting structure for the dome, acting as a unit, consists of concrete heavily reinforced with riveted sections. Four columns, as the respective corners of a 70-foot square, carry the load of dome structure and transfer it to the ground. Such columns (Fig. 3) are of concrete section twenty-eight inches square. They are composed of four 3 x 3 x 3/8 inch angles, doubled latticed with 2½-inch flats, and at the outside corners for additional reinforcement 3 x 3-inch T-bars are placed.

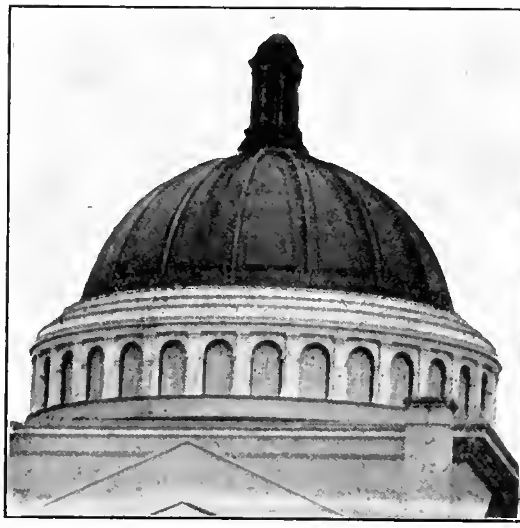

Fig. 1.

Fig. 2.

At the roof plane of the wings a girder framing is constructed, as shown in plan (Fig. 4). Four large girders "A" form the sides and rest directly upon the columns; at a forty-five degree angle at each corner, smaller built sections "B" are placed, and framing into these latter, as shown, eight small beams "C," approximately 14 feet long, complete a sixteen-sided polygon. This supporting structure is finished flush on top, the smaller girders being carried on brackets, and as a whole sustaining the main base of the dome.

The cross-section (Fig. 5) diagrammatically shows the construction of the main girders "A." The top chord is composed of two 6 x 4 x 3/8 inch angles, placed 12 inches apart and fastened with batten plates. The bottom chord comprises two angles, one 6 x 6 x 3/8 inch and one 6 x 4 x 3/8 inch, similarly spaced and battened. The verticals consist of two 3 x 2½ x 5/16 inch angles at the outer portion of the truss and two 2½ x 2 x 5/16 inch angles at the middle section, while the diagonals are formed of two 3 x 5/16 inch bars at outer end and two 2½ x ¼ inch bars at middle bay, correspondingly. All sections are riveted together at the joints, and the ends of girder riveted to the columns. A system of 1½-inch twisted rods for further concrete reinforcing is employed, as will be noticed.

The smaller girders "B" are of like construction, similarly reinforced with twisted rods, and riveted at ends into the main girders. The built beams "C," (Fig. 4) have top and bottom chord each of two 2½ x 2½ x 5/16 inch angles, battened 12 inches apart. There are two vertical and three diagonals in each constructed beam, the former consisting of two 2½ x 2 x ¼ inch angles, and the latter two 2½ x ¼ inch flats.

This steel supporting structure was erected successively, and then concreted as a unit, the timber form work for the latter being supported by the steel frame.

Dome Construction.—The forms for the dome were made in sections and located in position as the work progressed. The base of the timber forms rested upon studs concreted in the girder unit for such purpose. For three feet above the riveted section and concrete support, the dome is 16 inches thick, and is reinforced for such distance with two 1-inch bars at the base and six similar bars through the vertical or outer face.

The following section, about 8 feet in height, consists of thirty-two small posts, spaced equally about the circumference to serve for window jambs. These posts, 12 x 14-inch

in size, are composed of four ¾-inch twisted rods, additionally wrapped with No. 6 wire. The rods extend into the upper and lower bearing surfaces for a distance of about 6 inches to insure proper bonding. For 2 feet above this window area, the dome is of similar thickness, 16 inches, and is reinforced with five 1-inch twisted rods.

As will be noticed in Fig. 2, the remainder of the cupola rests on this 16-inch base, and forms a unit ring in itself. At the base, this dome proper is 8 inches thick and tapers to a 4-inch thickness at the crown. It is reinforced both vertically and horizontally with ¼-inch twisted rods, for the former at 18-inch centres, and for the latter in spaces varying from 6 inches at base to 12 inches at crown.

This complete section of the dome is covered with heavy-gauge copper which, as the crown is approached, assumes the shape shown by the wood frame in Fig. 5, this latter being added after construction was under way to insure a more graceful curve than originally planned. The wood frame consists for the most part of timbers 2 x 10-inch, 1 x 8-inch, or less, and is covered with 1-inch vertical sheeting. Surmounting the crown is a pinnacle of copper covering corresponding to the dome proper, as will be seen in Fig. 2.

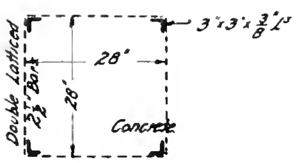

Fig. 3
Column Section

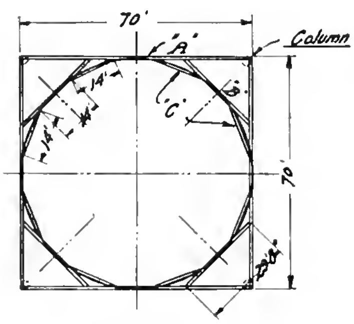

Fig. 4
Plan- Concrete Girder Support

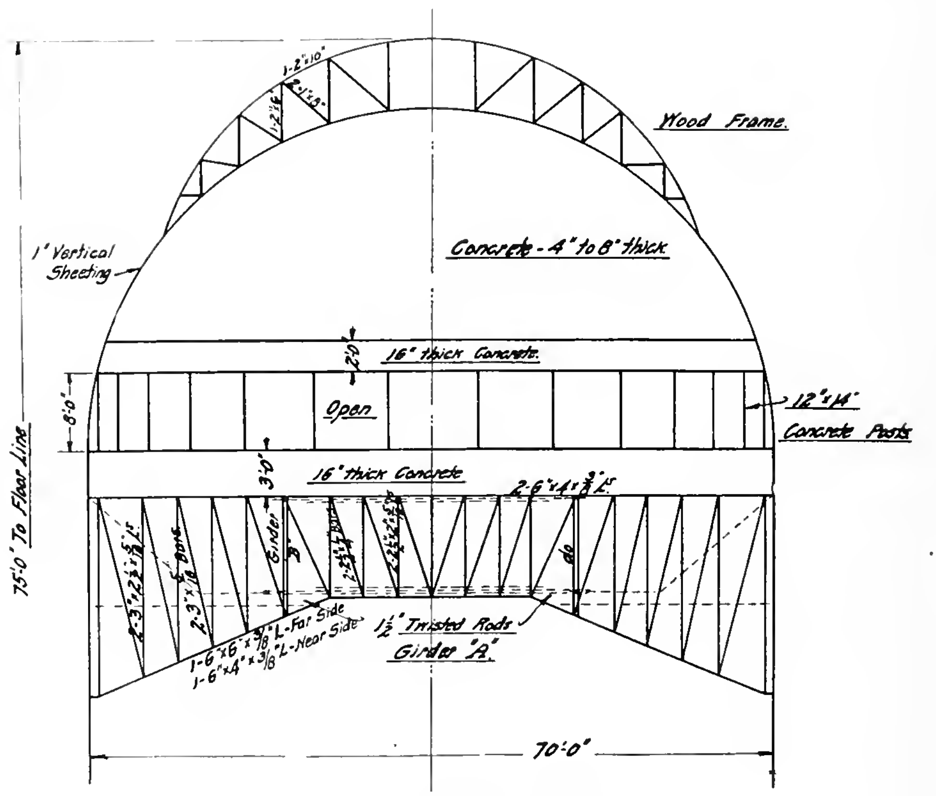

Fig. 5.—Diagram, Typical Section.

All horizontal reinforcing bars in the dome sections were placed near the outer edge of the work. The gravity system of pouring concrete was employed, the mixture was hoisted to a point above the work and conveyed to its respective location by means of a swivel-jointed, sheet-iron pipe. The forms for the dome construction were left in place for about three months.

The exterior finish of the church is a combination of terra-cotta and white enamel brick. This facing is fastened to the concrete body by galvanized wires, placed in position as the concreting progressed.

A. F. Rosenheim and A. C. Martin, both of Los Angeles, were associated as architect and engineer, respectively, of the edifice; the construction was carried out by the C. J. Kubach Company of the same city.

THE INTERNATIONAL GEOLOGICAL CONGRESS

By H. Mortimer-Lamb.*

Within the last twenty or twenty-five years, the science of geology has developed in a direction that has brought it into direct and serviceable association with those classes of commercial enterprise that are dependent on engineering. While this is especially true in respect of mining, it applies almost equally to railroading, municipal engineering, and other activities of a like nature. The dependence of mining on geology is attested, for example, by the fact that a geologist is now invariably included on the permanent staff of every mining corporation of importance; and the demand in recent years for the services of capable men to occupy such positions has been quite out of the proportion to the supply. It is recognized universally, in short, that the debt of the mining industry to geology is enormous, and the obligation continues to increase steadily. This largely explains the circumstance that the invitation to the International Geological Congress to hold the next meeting in Canada was made, not only at the instance of the Canadian and Ontario Governments, and of the Royal Society of Canada, but at that of the Canadian Mining Institute, an association representative, in a truly national sense, of the mining industry of this country. It is believed that this meeting will immensely benefit mining in the Dominion. From the educational and the scientific standpoints, much is to be expected from the interchange of views on Canadian conditions and problems, by men of international reputations. On purely commercial grounds, the interest and attention that will be directed to the mineral resources and to the opportunities for the investment of capital in mining undertakings in Canada, in themselves fully justified the extensive preparations that are being made and the expense that is being incurred in anticipation of the event. Judging from the character of the attendance in the past, almost every civilized nation will be repre-

* Secretary, the Canadian Mining Institute, Montreal.

sented at the Canadian meeting by men of recognized eminence, including distinguished government officials, geologists and mining engineers in consulting practice, geographers, great educationalists and writers of text-books. Thus surely never a better, a more effective opportunity has presented itself of providing for the wide-spread disseminations of authoritative information on Canadian resources and potentialities.

On these grounds, a general appeal for sympathetic co-operation is made to all classes and to the mining community in particular. The congress has held many meetings in other countries. In all, it has been welcomed with open arms. That record must be at least maintained.

Meanwhile, before proceeding to recount what progress has been made so far with the arrangements for the meeting and for the instruction and entertainment of the visitors, a word or two should be said concerning the International Geological Congress itself. In the year 1876, at the International Exhibition at Philadelphia, there was displayed a collection of geological maps and sections from both America and Europe. It had the effect of impressing on geologists who saw it the advantage of providing opportunities and means for comparative study; and in consequence, in August, 1876, at the annual meeting of the American Association for the Advancement of Science, at Buffalo, under the presidency of Prof. William B. Rogers, the project of the foundation of the congress was broached, received favorably, and a committee was appointed to arrange for the first meeting, held two years later in Paris. It is worthy of remark that the secretary of the committee in question was that distinguished chemist and geologist, Dr. T. Sterry Hunt, who from 1847 to 1872 was chemist and mineralogist to the Geological Survey of Canada. The objects of the congress may be very briefly and succinctly summarized in the general statement that by means of the periodical meetings the results of knowledge acquired in any one country are given a universal application and significance. The congress endeavors to provide, for example, for the adoption of uniform systems of mapping, nomenclature and classification of rocks, fossils and minerals; and in other directions broadens the boundaries and extends the usefulness of geological science. One achievement, in particular that may be mentioned, is the compilation of a geological map of Europe, shortly to be issued; and it is now proposed to undertake the preparation of a similar geological map of the world.

The records of the meetings, which are usually held every three years, are shown in the following table:—

Number of Members, Delegates, Vice-Presidents and Countries Represented at Each Congress.

Congress	Year	Country	Members Enrolled	Members Attending	Delegates	Vice-Presidents	Countries Represented
1st	1878	France	310		7	18	23
2nd	1881	Italy	420	224	23	19	23
3rd	1885	Germany	455	258	15	20	22
4th	1888	England	337	140	68	22	25
5th	1891	U.S.A.	546	251	39	31	24
6th	1894	Switzerland	401	273	18	15	20
7th	1897	Russia	1037	704	139	40	27
8th	1900	France	1016	461	80	46	31
9th	1903	Austria	664	393	39	25	30
10th	1906	Mexico	707	321	83	27	33
11th	1910	Stockholm	857	650	262	74	36

As will be noted, the congress, so far, has met only twice on this side of the Atlantic.

Socially and scientifically, the last meeting in Sweden was notably successful. The opening session was attended by the King of Sweden in person, while at the sessions devoted to the discussion of economic problems, a number of the Cabinet Ministers proved their interest and sense of the importance of the occasion by their presence. The arrangements for the conduct of the meeting, for the entertainment of the visiting scientists, and in connection with the several excursions, were planned and carried out with extraordinary ability and precision; and it will require every effort on the part of Canadians to even equal the standard set by Sweden in these respects. It is scarcely necessary to say, however, that no pains are being spared by an energetic and representative executive committee, to which has been entrusted the task of preparing a programme for the twelfth or Canadian meeting of the congress.

The excursions, more especially on the occasion of recent meetings, have been given special prominence. These have two main purposes; one to illustrate, so far as possible, the subjects discussed; and the other to afford visiting members the opportunity of studying the features of geological interest peculiar to the country in which the congress assembles. In connection with the arrangements for the Canadian meeting, provision has been made for over thirty excursions to mining districts and other localities of geological interest in Canada, between the extreme east and west of the continent, and northward as far as Dawson. It is computed, on the basis of the numbers in attendance at former meetings, that the representation from abroad, at the Canadian meeting, will not be less than, and may exceed, seven hundred. Each excursion will be under the leadership of a duly qualified guide, who will also be competent to point out and discuss the phenomena constituting the point of interest in each instance. Obviously, the planning and effective conduct of a series of excursions on this scale is no light undertaking; but with the assurance of local aid and co-operation, the difficulties should not prove insuperable.

The Swedish meeting was marked especially by the publication of a monumental work on "The Iron Ore Resources of the World," to which reports on the distribution and supply of iron in the respective countries were contributed by eminent authorities. The executive committee of the twelfth congress are to be very heartily congratulated on the decision to emulate this example by undertaking the compilation of a companion work on the "Coal Resources of the World." Incidentally, this report should serve to direct wider attention to the magnitude and value of Canadian resources. The subject of coal resources and supplies will, moreover, form one of the principal topics for discussion at the meeting in Toronto; while other topics of no less economic interest, notably that of the influence of depth on the character of metalliferous deposits, are to be debated.

It is unnecessary here, however, to further discuss details, the purpose of the present notes being to give merely a general idea of the aims and work of the congress and of the significance attaching to its meeting in this country. With a proper realization of the importance of the occasion, the mining men of Canada, no less than the public generally, may be trusted to cordially co-operate with the congress officials in making the Canadian meeting an unqualified success.

Further information may be obtained by applying to the secretary, Twelfth International Geological Congress, Victoria Memorial Museum, Ottawa.

REPORT OF THE TWENTY-SEVENTH ANNUAL MEETING OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

Report of Proceedings of the Twenty-seventh Annual Meeting of the Society, held at 413 Dorchester Street West, Montreal, on Tuesday, January 28th, 1913.

The President, Mr. Wm. Francis Tye, called the meeting to order at 10.30 a.m.

The first business was the reading of the minutes of the last meeting.

The Secretary then read the minutes, which the meeting confirmed.

The President stated that he was requested to call attention to the Introduction or Reception Committee and to its functions. As ordered at the last meeting an Introduction Committee had been appointed, and the members of it are, Mr. Jamieson, Mr. Lewis Skaife and Mr. Francis. If any of the gentleman would like any information or introductions, one of these gentlemen would be glad to do anything for you.

NOMINATION OF SCRUTINEERS

The following gentlemen were elected scrutineers for the election of officers, etc:—Mr. James Ewing (Chairman), S. Blumenthal, A. R. Ketterson, E. Fiset and Mr. Bates.

AMENDMENT TO BY-LAWS COMMITTEE

The following gentlemen were elected:—Mr. Openshaw (Chairman), Mr. M. A. Downes, and Mr. G. E. L. Mallory.

SPECIFICATIONS COMMITTEE

The following gentlemen were elected:—Mr. E. S. M. Lovelace (Chairman), Mr. Shanly and Mr. Oliver.

REPORT OF COUNCIL

The next business was the reception and adoption of reports. The first was the report of Council. The President asked if it had been distributed.

The Secretary (Prof. McLeod) Stated it had been distributed to the members and that it might be taken as read.

The President said this report of Council was very long and he thought they might take it as read. It would take up too much time to read it, and they all had copies of it. There should be a motion to receive this report. On the motion of Mr. T. C. Irving, seconded by Mr. Hunter the report o Council, as printed, was received.

The President said that they should first take up the report of the Council and afterwards pass on to the report of the Library and House Committee, and the other Committees. That report of Council ends on page fourteen, and the meeting must confine their discussion first of all to that.

The President asked if there were anyone wishing to say anything in regard to this report?

Mr. McNab said that he noticed the third paragraph dealt with the death of twenty-nine members. It seemed to him it would have been well if they had had the names of the departed confreres. Among those who were announced as deceased was one who was also a member of our Society. He referred to the late lamented Mr.Chandler. He would ask the Secretary to read the names of those—there are only twenty-nine—who have gone beyond.

Also, in the third paragraph it says that the number removed from the rolls aggregates forty-five. He would like to know what proportion of those forty-five were removed by straight resignation and what proportion by non-payment of dues, or if the two reasons go together.

The Secretary, answering Mr. McNab's questions as to the sub-division, there was a meeting some three years ago at which a statement was made to the effect that one gentleman had been removed for non-payment of dues and a certain number had resigned. That was taken exception to, and since that date they had been combined.

The Secretary then read the list of those who have died

Mr. Irving said the name of Mr. C. Beresford Fox of Toronto was not mentioned

The Secretary stated that he had nc information of that. He then read the list of resignations.

Mr. Mitchell asked if these were all resignations.

The Secretary assented and added that they are mostly students.

Mr. Mitchell felt that was rather a large number of resignations.

Could the Secretary give the proportion this year in comparison with former years, say five or six years ago? Was this number of resignations larger than usual, or smaller than usual; also, are these gentlemen those who are engaged actively in engineering work, or are they letting the Society go just out of lack of interest, or do they give reasons, such as having moved away, or having become engaged in other pursuits?

The Secretary stated that he could give detailed information if he referred to the correspondence. Answering Mr. Mitchell's first question, he did not think the number of resignations of corporate members has been as large as usual. The number of students is somewhat large because the Society are continually pressing them for payment of their dues, and they are continually going off into other lines of work than engineering and cannot make the transfer to the higher grade. Perhaps they do not desire to, but in many cases they cannot do so. That accounts for the large number of students who have resigned, but the number of corporate members is small. There are only five of the latter altogether. The actual causes for their resignations can be given, if required.

Mr. Leofred asked if the corporate members resigned because they think the Society is not useful to them, or something like that. They might say something in their letters to that effect. It would be interesting to know what they say.

The President stated that so far as he recollected he did not think they had had that advanced as a reason for any resignations during the year. It would take a very great deal of labour at the present time to produce all the reasons for the various resignations because it would be necessary to go through all the correspondence for the year.

Mr. Vaughan called the meeting's attention to the fact that this year both for non-payment and resignations only two members left, and 27 came in.

The Secretary stated that the actual number of those who were removed for non-payment of dues was 17 associate members, 2 juniors and 27 students. Some of these on the former list would exceed this return because the total right up to the year was now presented and was not available at the time this report was made in the middle of December. This would be corrected.

Mr. Thomson stated that the Society did not charge fees enough to run the society.

Mr. McNab stated that he would like to refer now to page twelve, in which there was a copy of a letter sent by the Secretary as representing the Council, to the Premier of Canada, the Premier of British Columbia, and the Ministers of Public Works and of Railways and Canals of Canada. He would like to ask if the replies to that letter could be read for the information of this meeting?

The President stated that the Council had received several very strong requests, from the British Columbia branch especially, to prosecute this, and that they were pressing it as best they could.

Mr. Robinson then moved that the report of the Council concluded on page fourteen, be accepted.

Seconded and carried.

The President next took up the report of the Library Committee starting on page fifteen and ending on page twenty-two.

Lt.-Col. H. R. Lordly stated that the report of the Library Committee showed that thirteen books were purchased during the year, and fifteen were presented, making a total of twenty-eight. One hundred and twenty-five dollars was expended, of which forty-nine dollars was donated, making a net sum of seventy-six dollars given by the Society. It was possible that owing to the purchase of the new building and expenses incidental thereto the Council had not deemed it advisable to spend any more money, but he believed that there was a connection between this and the number of resignations which were quoted a few moments before. The Library is so poor, the additions to it are so slim, that when you spoke to a young

man, an associate member, and ask why he does not come around and take an interest in the Society, he says, "You have no library, and there is no necessity for my spending fifteen dollars when I get nothing for it." No doubt there were good reasons for the small expenditure this year, but he thought it should be taken up and discussed seriously.

The President stated he thought the library was the best engineering library in the country. (Hear! hear!) Of course, it was not anything like so large as the Society would like to have it, but they had not the money to make it what they thought it should be, and everyone knew the expenses of the Society were mounting up very fast, and in addition to that the Society are moving this year, so the Council thought it inadvisable to buy many more books until they were in the new building.

In response to a question by Mr. McNab, the Secretary stated that as to researches, there have been practically no demands. The Society has facilities for having a research made by the Nelson Bureau of Research, and practically that has not been utilised this year, nor was it last year. There were one or two enquiries last year, so the research feature has not been patronised, although the attention of members has been called to it. There was no record kept of attendance, but he thought the average number of readers would not probably be more than half a dozen a day throughout the year.

Mr. Kennedy stated with regard to the matter of research that he had had occasion to pay quite a considerable sum to the American Society of Civil Engineers because they have a larger library running back a longer time, but if the Society had affiliation with some other concern so they could have such research he thought they would rather have it made through their own library, and it ought to be published and kept before them so they could understand it practically. The American Society have a number of transactions publishing announcements on such matters, and they are put in every time and so kept before the membership.

The Secretary here read from the certificate of membership issued in favor of the Canadian Society of Civil Engineers by the Nelson's Encyclopaedia Library for Research:—"Members are entitled to the educational benefits and privileges of Nelson's Bureau of Research for special information. Upon request, members will be furnished with accurate information on any subject desired, agriculture, astronomy, art, chemistry, electricity, engineering, economics, geography, history, civics, literature, and all allied subjects. All questions will be answered without further charge." The working arrangement is that any question sent in to the Secretary is communicated to the Nelson Bureau for Research. Since this has been posted there have been six or eight enquiries. (Good!)

Mr. Mitchell stated that he was sure the members who are non-residents were delighted to hear of that arrangement.

There was another point which occurred to Mr. Mitchell. The various governments, the Provincial governments, as well as the Federal government, publish various reports throughout the year with reference to their works of an engineering character. The Province of Nova Scotia may publish reports with reference to its road and bridge structures. It may be that members who are living in Saskatchewan would like to know what reports have been published during the year. It is true that those members could write to the Provincial Engineers, but they do not know what is published without writing a letter. It would be a very convenient thing if the Library Committee, through the Council, would publish a list once a year of such publications.

Mr. T. C. Irving asked if it were possible to get the branches of this Society placed on the exchange list of other technical Societies so they might exchange transactions.

The Secretary stated that if they were liberally disposed they might. These exchanges with the Society here have usually been made on the basis of exchange. He supposed some Societies might be willing to send to all the branches. He would be very glad indeed to make the representation.

Mr. Mountain agreed with the last speaker. He thought the Society might ask if other Societies do that, and call their attention to the fact that if any branches of theirs are formed, this Society would reciprocate.

The President thought this a very good suggestion and would refer it to the incoming Council and Library Committee.

On the motion of Mr. Lumsden, seconded by Mr. Blumenthal the report of the Library Committee was accepted unanimously.

The President said that the next order of business was the financial statement which begins at page twenty-three and goes to page twenty-six.

Mr. Mountain moved the adoption of that report.

REPORTS FROM BRANCHES

The President stated that the next business before the Society was the reception of reports from branches.

Reports were then read from Victoria, Vancouver, Manitoba and Ottawa. The first three were accepted

Mr. Uniacke, before adjournment, asked if the Ottawa report was open to discussion.

The President stated that the discussion would come. If you want to discuss it you can do so after lunch, and the motion would then be put.

At one p.m. adjourned accordingly.

AFTERNOON SESSION—JANUARY 28th, 1913

The President said that the meeting had finished reading the report of the Ottawa branch. He understood some members wish to discuss that report.

Mr. Robinson moved in so far as the report deals with matters pertaining to a report of the transactions of the branch of Ottawa, that it be accepted, and that such matters as are contained in that report recommending to this body something to be done, be referred to the heading of "New Business," to come up at that regular time.

The President said that this was satisfactory.

Mr. Mountain asked if it were new business arising out of the adoption of that report. If it was anything to be discussed it seemed to him it should be before the report was finally adopted. The only thing he wanted to refer to was the question of the number of students in the Ottawa branch that have reached their limit of age, and should be transferred. On behalf of the Ottawa branch he would call the attention of the Society to that with a view to its being taken in hand. These men could not be allowed to remain as students and pay one dollar a year, and the branch be out of the receipt of their percentages as corporate members.

The President said that the Secretary had been hammering away at that question as hard as he possibly could. He thought it was also up to the members of the Ottawa branch to move a little in the matter.

Mr. Mountain stated that they could not do that. They had tried to do that and the members of the Society represented that the branch was usurping the powers of the parent Society. It must be done through the parent Society.

The President said that he agreed with that.

The Secretary said that perhaps Mr. Mountain knew that a final circular had been issued to all of the students. There were some six hundred on the list to whom such notices had gone, informing them that unless they make application for transfer to a higher grade, or show that, they are still eligible to remain as students, they will be removed from the list on the first of March. He also said that the Council referred the matter to the Society solicitor in order to ascertain whether it was competent for the Council to transfer such students without their application, and he informed the Council that it was not, that they must make application.

Mr. Mountain said that answered his objection.

The President added he thought the Ottawa branch and the other branches would help along in that matter by urging these student members to make application.

Mr. Mountain said with all due respect to the Chair, that was impossible. They had been called down for attempting to do it.

Mr. Braley, as Secretary of the Ottawa branch, said that they had tried to get these members to transfer, but a certain number of them said they did not have to unless they were forced to. In fact, the question had been brought up that the Society could not force them to transfer because the By-Law for the age limit was passed just lately.

The Secretary said that there was nothing in that.

Mr. Jas. White said that there was another way out of the difficulty. If in accordance with the By-laws it is impossible to force these men to transfer, to change the By-laws. He suggested leaving the matter in abeyance for twelve months, but he did not see any reason why the By-laws should not be changed twelve months hence, and then let the parent association take action. Mr. Mountain had put the matter concisely. He did not know that they could do anything more.

The President said there was no doubt the parent Society was doing everything it could in that matter, and would continue to do so.

Mr. Braley asked if the Society could refuse them the transactions.

The President answered no.

Mr. Irving asked if the Ottawa branch was doing anything to have the very interesting papers read before their branch published in the transactions. They were having great difficulty in getting papers in Toronto, the members seemed to be very busy, and they were rather envious when they heard of Ottawa's success in getting papers.

Mr. Uniacke said it was their endeavor to get all those who have read a paper or given an address before the Ottawa branch to put them in such shape that they could be submitted to the Secretary and to the Committee on papers of the main Society. They had had several cases of papers that had been accepted, and he believed the Committee on papers at present had one or two under consideration. A good many of the papers and lectures had been of such a character that it was very difficult to put them in proper shape for publication. For instance, the paper on wireless telegraphy was a running talk illustrated by apparatus, and several others that were illustrated by lantern slides formed more of a talk, and the discussion brought out almost as much as the paper itself.

The motion that the report be adopted was then put and carried.

Mr. Robinson said he would like to interpolate a request to the Chair to reserve two hours some time during this Convention in which new business could be taken up. He thought the branch at Ottawa would like to bring up some of their suggestions, and he was sure others would like to do the same.

Mr. Braley said he had a few suggestions to bring up later on.

The President said that the next business that was on would give the opportunity desired.

Were there any representatives of Quebec here who could tell the Society anything about their report.

Mr. Leofred said that the Secretary telephoned him yesterday afternoon that he would be there to-day with his report.

The President passed that in the meantime. Kingston was in the same condition. Were there any Kingston gentlemen there?

They would leave those, and if they should get them before the meeting is over they could deal with them.

Regarding the financial report which was referred to the auditors, they say there are some clerical errors in the report as printed. On page twenty-three in regard to receipts the figure $539.72 should read $539.27; and on the next page this $10,000. That $85,141.84 on each side under the head of "Receipts and Expenditures" should be $75,141.84. With those corrections the report is all right.

FINANCIAL REPORT

The President thought there was a good deal of room for discussion in regard to this financial report, and he would be glad to hear from different members regarding it. The parent Society had reached this point where it had got to do something, it had to increase its receipts and reduce its expenditures, and there did not seem any way of reducing the expenditure, in fact it ought to be increased.

Mr. Braley thought the fees would be considerably increased when they moved the students up to Junior Associate Members.

The President said they would drop a good many students in the process of doing it, and he did not think that would make very much difference.

Mr. Mountain thought if the proposed increase of fees went into force the Society would be in pretty good shape.

The President assented but said that might not pass. Where was the Society going to be then?

Mr. Vaughan said he thought the meeting should talk over this proposed increase of dues, because as had been said it was possible it might not pass. If that increase did not pass it was going to put the Society in rather a serious position.

The Society had had some figures prepared in connection with that which he would like to present to the meeting in order that, should that proposed amendment to the By-law be defeated, the gentlemen from the various branches might be better informed as to the idea of the Council in this matter, as it would certainly have to be submitted again next year. These figures would be printed in the proceedings. They had compared the American Society of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, and our own Society, the Canadian Society of Civil Engineers.

The collections per member were: for the American Society of Electrical Engineers, $11 00; the American Society of Civil Engineers, $18.00; the American Institute of Mining Engineers, $9.50; the American Society of Mechanical Engineers, $17.25; the Canadian Society of Civil Engineers, $7.00.

The salaries paid per member are: for the American Society of Electrical Engineers, $2.25; the American Society of Civil Engineers, $5.20; the American Institute of Mining Engineers, $4.70; the American Society of Mechanical Engineers, $9.70; (He was a member of that Society); and the Canadian Society of Civil Engineers, $1.70.

The printing per member was: for the American Society of Electrical Engineers, $3.50; the American Society of Civil Engineers, $5.75; the American Institute of Mining Engineers, $4.60; the American Society of Mechanical Engineers, $10.70; the Civil Engineers of Canada, $2.30.

Those figures show how economically this Society is now being operated.

Another point that he wished to call attention to was the distribution of the $20,000 odd that went into the expenditure as outlined in the annual report. He had divided that into salaries, including legal and auditing expenses, which he considered a general charge very largely, charges of general benefit, such as printing the transactions, etc. He need not go over all these—but he had endeavored to take the charges of general benefit for the year amounting to $9,155. The headquarters expenses proper amount to $3,293.42, contributions to branches $2,810. That worked out about this way: Taking out total expenses, salaries are 24%, general expenses 45½%, headquarter expenses 16½%, branch expenses 14%.

Under the proposed new subscriptions the receipts as nearly as they could approximate from the headquarter expenses would be 23% and from branch members 36%, and from non-resident members 41% of the total. He had pro-rated the salaries equally among the headquarter, branch and non-resident members in proportion to the receipts from them; general expenses in the same way; the headquarter expenses entirely to headquarters, and the branch expenses entirely to the branches. The general result was that headquarters, from whom the receipts are 23%, take 31½% of the total; the branches, from which the receipts are 36%, take 39%; and the non-resident members, from whom the recipts are 41%, take 28½%. In other words, the branches were very nearly as well off, on the assumption that they were simply taking $12 for members and $10 for associates. Under the proposed By-laws the branches could, at their own option, increase that subscription to $15 for members and $12 for associate members, if they wanted the money, which would put them almost exactly on an equality with headquarters, and even then both branches and headquarters were getting more for their money than the non-resident members.

There was no doubt in his mind that this Society did need the headquarters. It was a benefit to the Society to have a headquarters maintained in proper shape. He did not believe they had gone to any unnecessary extravagance in the new quarters. They were the best that could be done with the money, and he did not think they could find them any too elaborate when the members saw them to-morrow. It was going to cost more to keep them up. As somebody said to-day, they should spend more on the library and that sort of thing. He was sure, from the inspection of the balance sheet they would find the increase asked for which simply put the members on an equality with members of other societies was not excessive. It was $15.00 for members. If they joined the American Society of Civil Engineers they would have to pay $25; the American Society of Mechanical Engineers, $15; the American Institute of Mining Engineers, $16.00; the American Society of Electrcial Engineers, $15.00; and the Canadian Society were asking $15.00. He could not compare associates, because their classification of associates was different from the Canadian Society. Their associates were people interested in the different professions, but not actively engaged in them; the Canadian Society Associates were actively engaged, but not of sufficient experience to be in the class of members. But if our associates are compared with the American Society of Civil Engineers associate members it is found that we were asking $15, and they were asking $25 for resident members. So even with this increase the Society were still well below other Societies of anything like an equal status, and it certainly would not give any more income than is necessary to carry on the affairs of the Society properly.

Mr. Vaughan thought that scheme of giving branches the option to increase their branch members to $12 and associate members to $10 so as to provide local funds for the branch would practically put their receipts almost on an equality with those of headquarter members, so far as what they get out of the total revenue of the Society compares with what the

headquarters members get out of the total revenue in proportion to the receipts from two different sources.

In connection with that the Council had recommended that the radius of branches be changed from fifty to twenty-five miles. That was with the idea that if the branch increased its subscription to $15 it might be very unfair to a member who was living thirty or forty miles away from headquarters to pay $15 instead of $10 for a non-resident member. There was no objection whatever to having members join out of the fifty miles radius, but they did not think it was fair to make it compulsory. He thought that was one of the things most criticised, but personally to him it was one of the fairest of the lot. If they get the option of $15 instead of $10 for a non-resident member the Society should limit the radius so that men who had no opportunity of getting in to the branches to take any interest in them should not be penalised an extra $5 for which they got no benefit.

Both branch and headquarters members were to-day, under this new schedule, getting more out of the Society in proportion to what they put into it than the non-resident members. (Applause.)

Mr. Uniacke said that Mr. Vaughan's schedule of fees and the reason therefor seemed to him to be very logical, but there was one point the speaker laid special stress upon, and that was that the branches at their own option should increase their fees on the same basis as the residents of Montreal, or the resident members. Under the wording of the By-law which had been sent out to be voted upon by the branches, it was a physical, if not a practical impossibility to do that, because it stated that in order to carry that it should be carried by two-thirds of all the members. In an ordinary ballot there was scarcely two-thirds of the ballots cast. So if it had stated "two-thirds of the members present at a meeting, after giving due and timely notice to everybody to attend that meeting," then there might be some chance of the branches carrying such a By-law.

There was one more point he wished to state. In the wording of the bylaw several clauses had been lumped together, and a man might have an objection to one or two clauses, but he had to vote "Aye" or "Nay" to the whole. Several had put it up to him that they would vote for this, but they had to vote for the whole thing together. Consequently if the By-law were defeated, it would be in a great measure due to that fact.

Mr. Vaughan thought Mr. Uniacke's point was very well taken about the two-thirds majority. It was a matter of common knowledge that it was almost impossible to get anybody to vote an increase of subscription by letter. He thought that amendment should be accepted and arrange to make a change in that, "that after due and proper notice two-thirds majority at the meeting should carry the change."

Mr. Coutlee thought that strong measures should be taken by the incoming Council to provide that either a larger percentage be given to the branches, or that a loan be made to them so they can put themselves on a respectable footing.

Mr. Irving asked if this were not a case where each branch could work out its own solution. As a matter of fact nearly all the members in Toronto pay thirty dollars to the Engineers' Club there. He thought in the case of Ottawa, Vancouver and Winnipeg, they could start an Engineers' Club and run the local branches of the Society as adjuncts to that Club.

Mr. Uniacke said in that regard that the Ottawa branch had under consideration combination of the three technical societies that were now in Ottawa for the joint use of rooms and lantern. They had a branch of the Mining Association on the same basis as the branch, and also an Association of Officers. They had a Committee on Rooms and the matter was now under consideration. If it went through it would help to put the branch on its feet, provided the members of the Ottawa branch, or the other branches, were a little more prompt in coming to time with their views.

Mr. Harkom said that the discussion was running on the question of headquarter's members and branch members. There had been a great deal said about not getting value for money from membership. He wanted, as a non-resident member, to put himself on record that he thought every member of this Society got full value for every cent he put into it. (Applause.) He thought it was worth $10 to any man to come here and attend these meetings. (Here! here!) For his part he did not think there should be the least little kick about increasing these dues. He had a certain amount of sympathy with these branch members from the fact that he really did not think they got quite enough to carry on their work. The work of the branches, really and truly was going to be, and is largely to-day, the true life of the Society. (Applause.) The branches should, he believed, get a little advance and if the Society was going to raise the dues of the branches two dollars, he thought they should have half of it added to their proportion.

The Secretary here stated that they were getting it all.

And if the fees were raised they would get the difference between the branch allowance for members and the headquarters allowance for members, $3.00. All that would go to the branch.

Mr. Uniacke said that was if the branches could carry that By-law.

Mr. Vaughan stated that he had omitted some information of what this increase would amount to. There would be 135 headquarter's members at $5.00, 400 branch and associate members at $2.00, and 200 headquarters associate members, or a total of $2,175.00 would be the estimated increase to headquarters on the general business of the Society, including all the general expenses. So it was not very much. It would add 12% towards the cost of operating the Society.

Mr. Mountain said that the trouble that had arisen between the branches and the parent Society was from the old By-laws under which they did not get any refund if a man was a year in arrears. He thought that was what started the whole trouble. In his opinion the Society was in a healthy condition, and it was representative of the engineers of Canada practising their profession to-day. He thought the members should keep it there

Mr. Braley thought everybody would agree that the branches to-day were helping to largely increase the membership. He had been Secretary in Ottawa for three years, and he thought they had pretty nearly corralled everybody there qualified to join the Society. Strong branches throughout the country were one of the greatest assets the Society could have. So long as the branches got a fair proportion of the increase he thought the branch members would be only too willing to increase the dues to the limit if they got a good return for the money.

The President here said this discussion was to a certain extent out of order, but he thought it was very important and he did not want to cut it short.

This question of fees was certainly very important. Canada was growing at a tremendous rate, and the Society wished to keep pace with the growth. The cost of living in every way was going up. It might be the cost of high living, not the high cost of living, but whatever it was it had the same effect on the Canadian Society of Civil Engineers as it had on everybody else and the Society must certainly have more revenue. It would be a calamity if this By-law were not passed. He was glad to have had the views of every man there. Speaking for the main Society, they certainly wanted to do everything they could for the branches, and he thought they could safely say there was no other Society of engineers that was doing anything like, for its branches, what the Canadian Society was doing.

Mr. Vaughan said that the Society might not have as good a branch organization as they ought to have, but they had a better branch organization than any other society he knew of.

Mr. Jamieson said that as the President had stated, the Society would be placed in rather a difficult position if the By-law should not be passed. If it should prove to be the case, he thought it would be well to put it before the members so they would know definitely the condition of affairs and what they were voting on. If that were done he did not think there would be any reasonable fear of its not passing. He did not think the members objected to paying towards ths support of the Society in a proper manner, but they ought to be given some information to base their judgment on.

The Chairman asked if the members were willing to adopt the financial report as corrected.

The motion was then put and carried unanimously.

The next business before the meeting was the reading of the President's address.

Mr. Mountain moved that the Vice-President, Mr. Vaughan, take the chair.

Motion duly seconded and carried.

Mr. Vaughan called upon Mr. Tye to read his address.

Mr. Tye then read his address

THE ADDRESS OF THE RETIRING PRESIDENT, MR. W. F. TYE.

GENTLEMEN :—

In rising to comply with the time honored custom of reading the President's address, I beg to thank you for the high honor you have conferred on me in electing me to the Presidency of our National Society.

Owing to my residence in Toronto, and to my absence in Europe during the first part of the year, I was unable to attend many of the Council meetings. The affairs of the Society were, however, so well looked after by the Council and our efficient Secretary, that I am sure the absence of the President was not felt.

I have great pleasure in congratulating the Society on its continued growth. Our Membership now amounts in all to over 3,000, and includes almost every engineer in the country. The expansion of the Society is a thing of which we must all feel justly proud. We have grown so rapidly that our old home has become too small for us, and we were very fortunate in being able to dispose of it on such advantageous terms at the very moment when a change had become necessary.

Our thanks are due to the Building Committee for the efficient and expeditious manner in which they have prepared a new residence for us; and I must congratulate the Society on the result of their efforts.

During the year the Council suffered a severe loss in the death of their friend and colleague, Mr. James N. Shanly. Mr. Shanly was a capable, conscientious engineer, and a favorite with all with whom he came in contact. He took a keen and intelligent interest in the Society's affairs. He was Chairman of the Finance and Building Committees, and much of the success of our new home is due to his untiring efforts.

When looking around for a subject on which to address you, my thoughts turn naturally to Railway Location, on which a great part of my professional career has been spent.

Transportation is one of Canada's greatest problems: our country is of vast area, the distances are great, the population sparse, and the traffic light; making the mileage and cost of railways high per head of population. On the other hand the growth of the country is and will continue to be rapid. A great problem is thus presented: how to build our railways that they may not be too expensive for our present requirements, and yet be capable of improvement to fit our future needs. Economics of Railway Location is, therefore, of even more than usual importance to Canada. The subject is so vast that it is only possible in such an address to touch its outer fringe; but it is so important to us all that even a few rudimentary remarks may be interesting.

While railways are built to serve the traffic requirements of the country, the immediate object of the promoters and builders is to make a profit, either on the construction or operation. This is undoubtedly true when built by private parties. When built by a Government, it is with the end in view that the people may make money either directly through the operation of the railway, or indirectly by the reduction of rates. It is, therefore, of prime importance that the engineer, whether he be working for private parties or for a Government, locate and construct the most economic road. The most economic road is not necessarily either the cheapest or most expensive, neither is it necessarily the one which may be operated at the least cost—it is in reality the one which is the most effective commercially or the one which will enable its owners to transport the largest amount of traffic at the lowest cost.

In order to ascertain that a railroad is most effective commercially, the features which underlie its commercial effectiveness should be understood. These are:—Gross Earnings Operating Expenses, and Fixed Charges; and are of importance in the order named Gross Earnings, which depend on the amount of traffic handled, is undoubtedly first. It is never advisable to build a railway unless there is or will be sufficient traffic to pay the Operating Eapenses and the Fixed Charges, no matter how cheaply or how well it can be built.

In new countries, such as most Canadian railways are built through, there is rarely sufficient traffic in sight to justify the construction of a road, so the promoters—whether they be a Government or private parties—must have faith in the project and must be able to justify to themselves, and to the investing public, the possibilities of paying dividends.

Engineers are sometimes, though rarely, consulted in the early stages of the project to report on the traffic possibilities of the route. The usual way is for the promoters to decide for themselves that a road between certain terminals is commercially desirable, and that there is or will be sufficient traffic on such a route to justify its construction. Engineers are then employed to survey and construct the road. The question should at once arise with the engineer—how the railway can be so located as to make it the most effective commercially, or how to get for the promoters the most profitable traffic. No matter how this problem is stated, it finally resolves itself into this:—if the promoters be private parties, how can the road be so located and built that the most interest can be earned on the money invested—or if a government, to transport the most traffic at the least cost? The answer in either case would be the same, for, if it is so located that it may handle the most traffic at the least cost, it will, if properly managed, make the most interest on the money invested.

The first problem the engineer has thus to face is how he can so locate the road between the given terminals as to get the most profitable traffic. The route which takes in the greatest number of towns, or which goes through the best land, if the country be unsettled, should be the first examined. A mistake frequently made is to locate the road within a mile or two of an important town in order to decrease distance or avoid expense. The cost of handling traffic is the total cost from the door of the consignor to the door of the consignee, and rates on that basis must be equal. The added charge for cartage is at times so large as to wholly destroy the business of the badly placed line and give it to a competitor more favorably situated, or if it be not wholly destroyed, the additional cartage and delivery charges eat up the profits.

Where traffic is light, and train loads less than the rated capacity of the locomotive, the cost of handling additional traffic is much less than is the ordinary train mile cost. It should be figured in equating the value of a change in location which increases traffic at 50% of the usual train mile cost. In this respect it should be remembered that deviations from the direct route do not always materially add to the length of the line.

In order to locate a railway so that it may be commercially effective it is first necessary to know what the volume of traffic is likely to be, whether it is immediately available, and at what rate it is likely to grow. The best way to ascertain this is by comparison with roads through the same or a similar country. A road through a country most nearly approximating that to be traversed should be selected for examination, and its traffic for previous years studied. If, for any reason business is likely to be materially greater or less than on the road under examination, due allowance should be made.

All railways are now required to make yearly reports to the government, and such statistics should be examined as well as those published in the Railway Companies' Annual Reports. The average train load and the ruling grade should be studied, and finally the average number of trains per day should be ascertained. It must be remembered that though the traffic is rarely balanced, that is, that there is seldom as much tonnage moving one way as the other, the number of trains each way must within narrow limits be the same. It is not always easy for an outsider to ascertain the number of trains over any given railway, as railway statistics are not published in this form, but every effort should be made to arrive at it as closely as possible.

Having obtained this information, and having determined how the traffic on the proposed road will compare with that on the road under examination, some approximation of the ruling grades on the road in view should be arrived at. If different from those on the route with which comparison is being made, the number of trains per day each way on the proposed road should be increased or diminished accordingly.

While this method of ascertaining the number of trains per day is only approximate, it is certainly much more accurate than to attempt to make an independent estimate of the gross tonnage on the new road. The rate of growth of traffic should be similarly ascertained, as a railroad should be built not only to take care of the present traffic but also that of the road in the reasonably near future.

Cost per train mile is the basis of all economic comparison, as the effect of the number of trains on the cost of operation is much more direct than

is the actual tonnage handled. The cost per train mile should thus be ascertained with reasonable accuracy. The Annual Reports published by the Railway Companies usually give these figures; if not, the reports of the Inter-State Commerce Commission give this information for every railroad in the United States. From this mass of statistics the train mile cost of the most nearly similar road should be taken and assumed as the train mile cost of the proposed road. It must also be remembered that these costs are increasing rapidly, the average for the whole United States for the year ending June 30th, 1896, being 95 cents, while for the year ending June 30th, 1910, it had increased to $1.49.

Equipped with this information as to the sources of traffic, the estimated average number of trains per day, and the probable cost per train mile, the engineer is ready to make a reconnaissance of the country to be traversed. The reconnaissance should always be of an area rather than a line. An area wide enough to take in any possible line should be examined. All combinations of probable lines should be studied. As the reconnaissance proceeds a map of the country should be made showing the details of the topography by contours ten to fifty feet apart; the elevations of controlling points should be shown with the greatest attainable accuracy. From such a map carefully prepared all lines and combinations of lines can be studied. Approximate condensed profiles can be drawn, and distances, grades and costs can be approximately asscertained. With such information, the choice of routes can usually be narrowed down to one or two, or in rare instances to three lines over which it is necessary to run surveys.

The value of a proper reconnaissance cannot be too strongly insisted upon. It is owing to the lack of it that the graver errors of location are usually due, such as the selection of an improper route or ruling grade, passing of traffic centres, &c. There is no way in which money can be so profitably spent. Great pains should be taken to secure the most expert engineer for this class of work. In engineering and economic importance reconnaissance far outranks location or construction. It is not an exaggeration to say that for every dollar which an engineer can save on construction, he can save five on location, and ten on reconnaissance.

The really essential factor in a location made for freight traffic is the ruling grade. The maximum is not always the ruling or limiting grade, as it might be operated by the aid of a helper engine, in which case it may not limit traffic. A very long grade of a lower rate may, by taxing the boiler capacity, become the ruling grade instead of a shorter steeper one. To ascertain the economic value of any change in grade, or to compare two different grades, the number of round trips per day required to handle the given or estimated traffic should be ascertained. The difference will be the saving in trains each way per day. This multiplied by the ascercertained cost per train mile, by twice the length of the Division in miles and the number of days in the year, will give the annual saving. Capitalizing at the proper interest rate will give the capitalized value of the better grade. If the additional cost is not greater than the capitalized value when properly equated for distance, rise and fall, curvature, etc., then the lighter grade is an economic one, and should be adopted.

As many items of expense will not be affected by changes in the number of trains, the saving per train mile for a train eliminated is not as great as the cost per train mile for the entire traffic. The saving is in reality in the neighborhood of 50%, and this percentage of the ascertained total train mile cost should be used in estimating the economy due to a difference in ruling grade.

In figuring on the economics of a grade reduction on an old road where the traffic and the average number of trains per day are known, it is essential that the actual loads hauled by each locomotive be determined and compared with their rated capacities. This difference is due to the inability of the operating officials to get perfect results. This "personal equation" must be taken into consideration in figuring the number of trains per day with the new grades, as they will no more be able to get the best results under the new conditions than they were with the old. In making a reduction from a high rate to a low, for instance, from a 1% to a 0.3% or 0.4%, it must not be forgotten that the proportion of the actual loads to the theoretical rating will be lower on the low grades than on the high. Time is an essential factor. On a 1% grade in good weather, the actual loading may usually be made 90% of the theoretical, while on 0.3% it is unlikely that more than 75% of the rating can be hauled if time is to be made.

The proportionate amount of ruling grade on the Division has also an important bearing on the loading of trains, the greater the proportion its length bears to the length of the Division the lighter the actual train loads must be, and this too must be taken into consideration in determining the average number of trains per day required to handle the traffic on the proposed new grade.

Serious error would undoubtedly arise if the theoretical number of trains required to handle the traffic on the proposed new grade were compared with the actual trains on the present one.

While Fixed Charges—which are largely determined by the "Cost of Construction"—are of lesser consideration than Operating Expenses, they are still of prime importance. No road can pay dividends to stock holders, or afford to reduce freight rates until its Fixed Charges are met. So it is of the greatest importance that the engineer introduce no features that will increase the cost of construction without reducing the Operating Expenses by at least as great an amount as the interest on the added cost. The cost of moving a given tonnage being the sum of the Operating Expenses and the Fixed Charges—it follows that a reduction in the cost which does not increase the Operating Expenses is only of less importance than one which reduces the Operating Expenses without increasing the cost. Such a reduction in cost is a practical improvement to the standard of the road, as it increases the margin between receipts and expenditures, and so permits of an increase in dividends, or has a tendency to permit of a reduction in freight rates, if that be the object aimed at.

In Canada most of the new construction is through districts which at the time of completion furnish but little traffic: much railway has been built on which the traffic did not justify even one daily freight train per day each way. It is a safe statement that 80% of the mileage constructed in Canada would not furnish at the date of completion traffic sufficient for two freight trains each way per day. Under such conditions, the receipts are low and the Operating Expenses high, and it is of the utmost importance that the construction cost be kept low. On the other hand, the country is growing fast, and traffic is increasing rapidly. It is thus necessary that the engineer keep always in view the almost certain necessity of a good road in the future. He should, therefore, so locate and construct his line that the first cost be low, and that the standard may be raised, when necessary, without unduly increasing the total expenditure. In order to get the very best results, the line giving best grades, alignment, etc., should always be first located. From this, as a standard, the engineer should work to the final or economic location. Working from a poor to a better is apt to lead to grave errors.

Where low construction costs are necessary, and it is probable that a high standard will be required in the future, it is much more effective and advisable to use short sections of temporary line with steep grades, sharp curves, etc., on the heavy or difficult sections, maintaining the higher standard for the light or easy portions of line, than it is to adopt a generally lower standard for the whole route. The first cost of the former will probably be less; it may be operated with helper engines as the traffic increases, and may be improved when advisable, while the cost of improving a generally poor road is frequently prohibitive.

The use of sharp curves with short tangents is often a very effective means of reducing cost without materially increasing the Operating Expenses.

The effect of moderately sharp curvature is essentially different from steep grades, inasmuch as it is not limiting in its effect. The use of one sharp curve does not justify the use of another just as sharp—whereas the use of one ruling grade on a division does justify another as steep.

The use of curves up to 14 degrees does not increase the maintenance or operating expenses. A mile of road in which there are 100 degrees of 10 degree curve, the balance being tangent, does not cost any more to maintain and operate than the same length of road with 100 degrees of 2 degree curve—in fact, if there is any difference, it is in favor of the sharper curvature.

Report of the Annual Meeting of the Canadian Society of Civil Engineers, held in Montreal, Jan. 28, 29, 30, 1913

Unless the curvature is so sharp as to be limiting in its effect, there is no serious objection even on the best class of road to a few sharp curves where the amount saved by their use is sufficient to justify their introduction. The conditions which cause curves to be limiting are when they are so sharp as to prevent the use of the higher grades of modern equipment, and when they limit the haulage capacity of the locomotives, or their speed.

Modern equipment is so constructed as to traverse safely 14 degree curves, and much sharper with guard and hold up rails. The standard compensation for curvature on grades is 0.04 foot per degree. A 10 degree curve is thus equivalent, as far as resistance is concerned, to a 0.4% grade; and a 15 degree curve to a 0.6% grade. On a 0.4% it is only necessary that the grade on a 10 degree curve be made level in order that the resistance be not increased. The same thing applies to a 15 degree curve on a 0.6% grade. It is, therefore, evident that on a road whose ruling grades are 0.4% 10 degree curves are not limiting to the haulage capacity of the locomotives, nor are 15 degree curves on a 0.6% grade.

The easy riding speed is dependent on the amount of the allowable elevation of the outer rail. If the maximum be set at six inches, this speed per hour would be :—

on a 3 degree curve		60 miles per hour	
" 4	"	50	"
" 6	"	40	"
" 8	"	35	"
" 10	"	30	"

The safe or allowable speeds would be 10 miles per hour greater.

With the track properly elevated, equiped with tie plates kept in good line and surface, and curves provided with proper easements, 10 degree curves are no more disagreeable to ride over at speed of 30 miles per hour than are 3 degree curves at 60 miles per hour.

The reduction in speed for one mile from 50 to 30 miles per hour only means the loss of 0.8 minutes. To take an extreme case—the Twentieth Century Limited runs from New York to Chicago, 980 miles in 20 hours, or at an average of 49 miles per hour. The introduction of one hundred 10 degree curves each one of which required a slacking of speed to 30 miles per hour for a distance of one mile would increase the running time of such a train by one hour and twenty minutes. Such an increase on a road 1,000 miles long would in nine cases out of ten have no ill effect. A 10 degree curve so long as to require the reduction of speed to an average of 30 miles per hour for a mile would in practice be a very rare occurrence.

It is evident the use of curves as sharp as 10 degrees does not prohibit the employment of modern equipment or limit the haulage capacity of the locomotives. It has no effect on the speed of freight trains, or on passenger trains where the average speed including stops is not greater than 30 miles per hour. A few such curves only slightly affect the running time where speeds are high.

It is thus clear that a few curves not sharper than 10 degrees are not objectionable on the very best roads where their use results in large savings. As they are not limiting, the use of one such curve is no justification for a second. The introduction of many of them preventing the employment of high speeds for long distances would certainly be objectionable, but an occasional one where large savings result is justifiable on even the highest class of road.

Wooden trestles to replace heavy rock borrow embankments should be used. Such trestles may be designed to safely carry the heaviest class of equipment. When protected by the installation of the best available water supply they are quite safe, and are good for ten years. Such temporary construction also gives time to ascertain the correct requirements for water ways in new countries where there is frequently a dearth of information as to rainfall, flow of streams, &c., and where unless unduly large water ways are left there is danger of washouts. This danger may be even greater than the danger from fire to wooden trestles. Their use instead of heavy rock borrow embankments is of great importance from an economic point of view. One dollar at 5% compound interest amounts in ten years to $1.63. If rock borrow costs on the original construction say $1.75 per cubic yard it will in ten years time have amounted with interest to $2.85. While, under anything like ordinary conditions train hauled earth embankments on an operated road, made when the trestles require replacement, do not cost over 30 cents per cubic yard, or less than one-ninth of the total cost of a permanent rock embankment made during construction.

Momentum grades are a great source of saving in cost without increasing the operating expenses. The use of momentum in overcoming short stretches steeper than the ordinary ruling grade is almost always justifiable. The exception is where the traffic is so congested that the possibility of a delay due to the failure of an occasional train to surmount the grade is more important than the undoubted saving in interest charges which they insure. It will probably be many years before conditions prohibiting their use prevail on any portion of our Canadian railways.

The foregoing are a few of the more important considerations which the locating engineer should keep in view. He should always remember that railways are commercial enterprises, are built for profit, and that the investors are looking for and are entitled to satisfactory interest on their money; and so far as the returns on their investments depend on location they will for a given traffic be the greatest when the sum of the operating expenses and fixed charges is the least amount.

A NEW STREET CLEANER.

A new idea in street sweeping by machinery has recently been introduced into England, having been used for some time previously in Milan, the inventor of the machine being an Italian. About the middle of December one of these machines was demonstrated before a number of municipal engineers and other officials from several English cities, picking up satisfactorily the customary assortment of sand, straw, small stones, etc., which are ordinarily scattered for tests of this kind. The machine is propelled and operated by a 20-30 h.p. 4-cylinder motor. Aside from the motor, it consists of a revolving broom carried between the fore and hind wheels, and a double dirt receiver which is carried behind the rear wheels. The revolving cylindrical broom has a diameter of 52½ inches, is 5 feet long, and is built up of twenty distinct small piassava brushes, each five feet in length, arranged along parallel elements of the cylindrical core of the brush.

The cylindrical broom revolves within a sheet iron shell in which it fits closely, at a speed of 120 revolutions per minute; which results in its not only raising the sweepings and carrying them two-thirds of a revolution and passing them through a specially contrived opening into the receivers behind, but the circumferential speed of the broom is said to create a sufficient suction in the cylinder to draw in all the dust and discharge it likewise into the receivers. It is also claimed that the velocity with which the broom revolves throws the refuse into the receivers with such force as to compress it and thus make the capacity of the receiver greater than if the dust merely settled in it.

The rear end of the compartment of the car which contains the two dust receivers is made in the shape of a large door hinged at the bottom which, when opened, forms an incline platform down which the filled boxes are rolled to the ground, each box being furnished with three small wheels or castors. The receivers or collecting boxes are of sheet iron and have a capacity of 50 cubic feet.

The total weight of the car with the receivers empty is 6,450 lbs. It is claimed that the cost per hundred thousand square feet of cleaning with this machine was $1.86, as compared with $11.18 with horse sweepers.

Report of the Annual Meeting of the Canadian Society of Civil Engineers, held in Montreal, Jan. 28, 29, 30, 1913

REPORT OF THE COMMITTEE ON CONSERVATION OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

The field of conservation, so far as it affects the engineering profession, is so vast that it was deemed inexpedient to deal with more than one phase of it. At the last annual meeting a communication from Mr. Sauder was addressed to the Society and, later, referred to the Committee on Conservation. Mr. Sauder wrote:

"Whereas the water supplies, water powers, navigation of our "rivers, irrigation of our semi-arid lands, drainage of our over-flow "and swamp lands and the sanitary conditions of our streams and "their water sheds generally are a great asset.

"Whereas an accurate knowledge of a flow of water in nearly "all important streams is essential for the solution of many problems "in connection with navigation, water power, irrigation, domestic "and industrial water supplies, mining, bridge building, river channel "protection, flood prevention and storage for conservation of flood "waters.

"Whereas it is the opinion of the Society that the matter of the "topographical and hydrographic surveys to determine the location "and quantity of water supply and the proper methods of conserving "it should be undertaken by the Federal Government.

"Therefore be it resolved: That this Society, while recognizing "the work already done, urges strongly upon the Dominion Govern-"ment the importance of making the necessary appropriations and "providing the necessary staff to undertake in an intelligent and sys-"tematic manner, the gauging of all streams of water supply and the "location and survey of all sites suitable for reservoirs for the storage "of water."

This letter was referred to the members of the Committee and the concluding statements of the report embody the substance of the replies received from them. In view, however, of the importance of the subject it was deemed advisable to take this subject—Water Supply and its Conservation in Canada—as the special subject for this year's report.

When planning to develop a water power or a navigation channel, the first consideration is: What is the minimum flow? The speed of a squadron is the speed of the slowest vessel and, speaking generally, the minimum flow is a determining factor in a water-power or a navigation project. The minimum flow may often be increased by storage in reservoirs but the initial step is to determine its amount and the maximum period that it may be expected to continue.

In arriving at anything approaching a reliable estimate of the minimum flow of a stream, a series of continuous gaugings extending over a considerable period is absolutely necessary. George W. Rafter, in Water Supply Paper No. 80, published by the U.S. Geological Survey, says:

"Further, it can be stated that, for records from twenty years "to thirty-five years in length, the error may be expected to vary "from 3.25 per cent. down to 2 per cent., and that, for the shorter "periods of five, ten and fifteen years, the probable extreme devi-"ation from the mean would be 15 per cent., 8.25 per cent. and "4.75 per cent. respectively."

Rafter says, further, that with less complete records,

"Mr. Henry reached the conclusion that at least 35 to 40 years' "observations are required to obtain a result that will not depart "more than $\pm$ 5 per cent. from the true normal. The average vari-"ation of a 35-year period was found to be $\pm$ 5 per cent. and for a "40-year period $\pm$ 3 per cent."

From the foregoing, it is evident that unless the engineer is in a position to allow a margin on the safe side, he should have continuous gaugings extending over at least ten years. As an example of an erroneous estimate based on insufficient data, the Rainy River at Fort Frances may be cited. Three engineers, reporting separately, estimated the power at 30,800, 33,000 and 34,741 horse power respectively. In the summer of 1911, they were able to generate less than 11,000, and, to do this, it was necessary to keep the stop-logs in all day Sunday, thus stopping navigation. Had gaugings extending over, say ten years, been available, no such over-estimates would have been made and, had they included the very dry season of 1895, they would, probably, have shown as small a flow as in 1911.

Canada is particularly favoured as regards reservoir possibilities. The whole of the northern portion of the Dominion is occupied by a series of granitic rocks, which have a U-shaped form and surround Hudson Bay. This area has been called the Archaean nucleus and, considered in the large, it forms a great plateau. To quote the words of the late Dr. G. M. Dawson,

"It constitutes, moreover, a gathering ground for many large "and almost innumerable small rivers and streams, which, in the "sources of power they offer in their descent to the lower levels, are "likely to prove, in the near future, of greater and more permanent "value to the industries of the country than a great coal-field"

The foregoing was written sixteen years ago, and, with the tremendous strides in electrical engineering, is even truer to-day than then.

The most remarkable features of this Laurentian area are the innumerable lakes which serve as natural reservoirs to regulate the run-off and which can, in many cases, have their storage capacity increased by damming.

In considering the work of stream-gauging in Canada, the provinces have been dealt with in geographical order from East to West.

In the Maritime Provinces, the streams are small and very little gauging has been done except on the St. John River and some of its tributaries. The work on the St. John has been undertaken as a result of differences between Canada and the United States respecting the provisions of the Ashburton Treaty affecting this stream. The St. John above the Allagash and at Fort Kent, the Allagash, St. Francis, Fish, Madawaska and Aroostoock have been gauged. Measurements have also been taken on the St. Croix River which forms the Southern boundary between New Brunswick and Maine. So far as ascertainable, nothing has been done in the way of investigating sites for reservoirs except the reconnaissance surveys made by the Commission of Conservation in 1911.

In Quebec, the more important power companies keep records of the streams on which they are operating. Between lake St. Francis and Sorel, the Department of Public Works has at present nine gauges. Two of these gauges are of the self-recording type and four others of the same type will be in operation next summer.

The Department of Public Works has sixteen gauges on the Ottawa River, and also maintains gauges on its important tributaries. The Engineers of the Georgian Bay Ship Canal, appreciating the importance of stream measurements, made in their report the following recommendation:

"That it is of great importance to continue every year the flow "measurement of the Ottawa, Mattawa and French Rivers, at low, "ordinary and high water stage, in order to have continuous records "of same, which will prove invaluable in the further development "of the canal problem, in case of construction, and a better knowledge "of the water-power possibilities."

On the Richelieu River, the depths on the lock sills of the Chambly canal, at St. Johns, have been recorded daily since 1869 and the level of lake Champlain has been noted daily at Fort Montgomery, N.Y. since 1871. At Montreal, the depths of water on the lower lock sill of the Lachine canal have been measured at noon each day since 1851.

The Province of Quebec has appointed a Commission with the Hon S. N. Parent, as Chairman. They have recommended the construction of a large dam on the upper waters of the St. Maurice to regulate the flow and have three parties in the field making topographical and hydrographic surveys of various rivers in the Province.

On the St. Lawrence above Montreal the depths on the lock sills have been recorded since 1860. These, therefore, give an excellent series of gauge readings for the river at lake St. Louis, lake St. Francis, Long Sault rapids, Farrans Point, Morrisburg and Cardinal. Similarly, the canal records at Ste. Anne, Carillon and Grenville determine the regimen of the Ottawa since 1870, while the lock depths at Ottawa extend back to 1844. For lakes Superior, Huron and Erie, the records cover the period since 1860, while the Toronto gauge records of lake Ontario extend back to 1854.

In the western portion of Ontario the Departments of the Interior and Public Works have established one gauge on Rainy Lake and five on Rainy River. Next summer five of them will be replaced by self-reading gauges. In connection with the investigation of the water-levels of the Lake of the Woods, the International Joint Commission will establish others on the upper waters of the Rainy River.

So far as work by provincial governments is concerned, Ontario is much the most advanced. Its Hydro-Electric Power Commission has established gauging stations on a great many of the streams of the province and is carrying on the work of stream-gauging in a thorough and systematic manner; possibly the only improvement in this connection would be the establishment of additional stations until all the streams of importance are included in the work.

The powers conferred upon the Commission in this connection may be described as follows:

"It is duly authorized to investigate and report to the Lieutenant-Governor-in-Council upon any and all hydraulic, hydro-electric and other power undertakings, whether developed or undeveloped, throughout the Province."

In connection with the waterpowers of the Winnipeg River, the Water Powers Branch of the Department of the Interior has investigated the water resources of the Lake of the Woods drainage basin. In conjunction with the Department of Public Works, gauging stations have been established on Rainy River and certain important streams falling into Rainy Lake and a study has been made of the outflow from the Lake of the Woods.

While in the Maritime Provinces, Quebec, Ontario and British Columbia, except the Railway Belt and Peace River Block, the water powers are disposed of and are under provincial jurisdiction, in the Prairie Provinces, Manitoba, Saskatchewan and Alberta, they are under the control of the Dominion Government. This right was reserved when the provinces were created with a view of better conserving their waters as a whole and for this purpose a large forest area on the eastern slope of the Rocky Mountains has, recently, been segregated by the Dominion.

In Manitoba, the Water Powers Branch of the Department of the Interior has established stations on the more important rivers where information is required in connection with waterpowers, drainage, navigation, etc. The work is being gradually extended over the whole province to meet the economic conditions.

The Dominion Government has, for some time past, made investigations of the flow of streams in the latter provinces and, although these investigations were more particularly for irrigation purposes, they also have an indirect bearing on waterpowers. The following is an extract from one of the reports on this work:

"The records of stream flow published by the Irrigation Surveys give a fair approximation of the discharge of the principal streams in Southern Alberta and Saskatchewan at the different stages, but do not give the duration of the periods of high and flood discharge. As the water supply in some of the larger streams is apparently almost all recorded, the necessity of carrying on a systematic observance of daily discharge is evident.

"The chief features of the hydrographic work are the collection of data relating to the flow of the surface waters and the conditions affecting this flow. Information is also collected concerning the river profiles, duration and magnitude of floods, waterpower, etc., which may be of use in hydrographic studies."

"In organizing the Hydrographic Surveys it was realized that with the funds available, it would be impossible to make complete investigations of the whole of the water supply in the irrigation tract, but an effort was made to include all the more important streams. Gauging stations had already been established, by the Irrigation Surveys, on a number of the more important streams, and it was important that the observations at these should be continued without interruption. There were, however, many streams of considerable importance upon which there were no gauging stations. It therefore became the policy of the survey to continue the investigations at the stations already established and to establish other stations as soon as possible."

Unfortunately, as the work is being pursued in connection with irrigation, it does not include any figures for the winter season, which additional data would be of great value from a waterpower standpoint; this is recognized in the following quotation also from the report above cited:

"On streams where power is likely to be developed, special attention should be given to the low water flow, which in most cases occurs during the winter. For this reason it is very important that stream measurements should be continued during the winter on a number of the more important streams."

In British Columbia, the Water Powers Branch has a permanent organization known as the Railway Belt Survey. Gauging stations have been established on the important water-power rivers in the Railway Belt and special attention has been given to the streams in the so-called "Dry Belt."

During 1911 and 1912, the Commission of Conservation made reconnaissance surveys of water-powers in southern and central British Columbia and this work will be continued. In 1912, the Department of Lands of British Columbia, recognising the value of this work, appropriated nearly $2,500.00 in addition to the amount expended by the Commission of Conservation and will, this year, make a grant of $5,000.00. This work, however, is only in the nature of a reconnaissance and, wherever the development of the country indicates that the water will be economically usable, it should be followed up by such measurements as the Water Powers Branch of the Department of the Interior is now carrying on.

The great importance of systematic stream gauging in Canada cannot be over estimated. On the information furnished by the Government will depend to a great extent the development of water-power. Very often, before designing a development, the hydraulic engineer has to spend a year or more in making observations which in many cases are practically useless, because they do not cover a sufficiently long period, and the result is that the possible development is either much over-estimated or, in other cases, much under-estimated.

Although most of the waters of Canada are under provincial control, this matter of stream gauging is not only important to the different provinces but it is of national importance, and the Federal authorities should undertake the gauging of Interprovincial and International rivers to collect this all-important data in a systematic and uniform manner.

The Provincial Governments could make a beginning by devoting their attention altogether to the establishment of stations where the water levels only would be read, leaving, if necessary, for future years the systematic observations required to convert these water heights to discharges. It was in this manner that it has been possible to calculate the different discharges of the Ottawa River since 1844: water-levels only had been kept since that date by the lockmasters of the canal at Ottawa and it was only comparatively recently that observations were taken to convert these water-levels into actual discharges.

For the present, of course, it would be out of the question to have these stations on all of our streams, but a start might be made on the more accessible ones or those on which storage and conservation will become a necessity or a natural outcome at some future date. At present, there are very few streams in Canada on which artificial storage or conservation is being practised, because it has not yet become commercially economical or necessary to do so. When the power possibilities of a stream under natural flow have been exhausted at one site, other sites, nearby, on the same or other streams have been found and developed, this requiring less outlay per h.p. than would have been required to conserve the flow of the stream. But this cannot go on forever, and a time will come when the last site within an economical radius will have been secured and the conservation of the stream will have to be resorted to in order to satisfy the increasing demand for power. When this time comes, in order to develop a conservation scheme on any stream intelligently, it will be necessary to possess a complete history of the flow of the stream under consideration for a period of at least from ten to fifteen years previous, and, unless a beginning is made now on the history of flow of some of these streams, when the time comes to conserve them the data at

Report of the Annual Meeting of the Canadian Society of Civil Engineers, held in Montreal, Jan. 28, 29, 30, 1913

hand will be found very meagre and the conservation scheme will have to be designed in a more or less haphazard manner.

With federal co-operation, the system now practised in Ontario could probably be continued and extended to comprise other streams and establish new stations more rapidly.

In Quebec and the Maritime provinces, much data on this subject could no doubt, first of all, be collected from private parties or large hydraulic plants where records of river heights have been kept, and a system similar to that of Ontario or a modification to suit local conditions could be started at once and the returns from the different stations throughout Canada sent to their provincial authorities as well as to Ottawa, where they could be tabulated in a uniform manner and printed for easy access to the public.

Other countries with less water-power possibilities than Canada have devoted a great deal of attention to systematic observation of stream flow, namely: Italy, Switzerland, Bavaria France and other European countries. In the United States, the Geological Survey has, for years, devoted a great deal of attention to the subject of stream measurement and has developed an excellent system, both of carrying out the work in the field and of reporting and tabulating the data obtained.

In Canada, one of the greatest difficulties to be overcome in connection with this work is the taking of observations during the winter season, as practically all our streams are then frozen over. These difficulties, however, can be overcome and they are always more than balanced by the importance of obtaining complete and reliable data during the very time when the rivers are in this condition.

In a report on "Stream Flow during the Frozen Season," Messrs. H. K. Barrows and R. E. Horton of the U.S. Geological Survey say in part—"There is not even an approximate relation between the snow-fall and the stream flow, so that the failure to obtain winter records of flow at a gauging station means a considerable percentage of uncertainty as to the total run-off as well as its distribution. In the Northern states droughts are apt to occur in the late summer or fall and during the winter. At times this condition of drought may be nearly or quite continuous between these two periods, with its culmination in January or February. If there is no melting of snow during the winter, the inflow to streams that freeze is chiefly derived from springs, ground water, and lake storage and in a long, cold winter, especially if it succeeds a period of low water, the minimum flow for the year may be reached and continue for some time. Estimates of flow, therefore, to be of conclusive value on streams utilized for water-power, must embrace these winter periods of low water."

It is needless to add that the winter conditions which occur in Northern United States rivers are found even in a more marked degree in Canadian rivers, and it follows that the statement just quoted applies with a proportionately greater force to Canada.

Summing up, the Committee on Conservation is of the opinion that, while the work recommended by Mr. Sauder, viz., topographical and hydrographical surveys to determine the situation and quantity of water supply, should be undertaken by the Dominion Government, and is of great importance, it is probable that the Government is, at the present time, carrying on more extensive and detailed investigations of this nature than is generally appreciated. That, while a certain amount of concentration to avoid duplication and overlapping of work is necessary, the scale upon which the work has been initiated indicates that the needs of the country in this respect will be met.

That the work already done is of great value but that much of it is not, in its present form, available to the engineers and

That steps should be taken to secure such publication and distributiou of this information as will bring it within the reach of each and every engineer in Canada.

JAMES WHITE
Chairman

REPORT ON THE VISIT OF MEMBERS OF THE INTERNATIONAL CONGRESS OF NAVIGATION TO CANADA IN JUNE, 1912.

On March 6th, 1912, Col. W. P. Anderson, Chief Engineer of the Department of Marine and Fisheries, acting for the Department, addressed the Council of the Society to the effect that the members of the International Congress of Navigation had been invited by the Canadian Government to visit Canada on the conclusion of the sessions of the Congress to be held in Philadelphia in May, 1912. Col. Anderson intimated that the Dominion Government had voted $20,000 to provide for the expenses of the delegates and that of this sum $5,000 would be required for the necessary official publications, the remaining $15,000 being available f r transportation and incidental charges. He also stated that Major G. W. Stephens, Chairman of the Montreal Harbour Commission, who had been officially nominated by the Government to represent Canada at the Congress, had recommended that the Canadian Society of Civil Engineers should be invited to organize the proposed visit to Canada, and asked if the Council would be willing to undertake the work of outlining a programme and make the necessary arrangements for carrying out the excursion.

At a meeting held on March 9th the Council acquiesced in the proposal and appointed a Committee consisting of Messrs. H. Holgate and H. H. Vaughan, Vice-Presidents of the Society; Mr. Ernest Marceau, Past President; Messrs. C. N. Monsarrat, J. N. Shanly, W. J. Stewart and P. E. Parent, Members of Council; Mr. A. St. Laurent, Department of Public Works, Ottawa; and Professor C. H. McLeod, Secretary of the Society, to confer with Major Stephens and report. This Committee met Major Stephens, and as a result of various conferences with him and with the Department of Marine and Fisheries through Col. Anderson, the following programme was outlined and received the approval of the Council of the Society and of the Department of Marine and Fisheries on behalf of the Government of Canada. It was understood that the Society, represented by its Council and special Committee, would act for the Government in receiving the foreign guests and conducting them to the various places named and works of engineering and commercial interest of the Dominion. It was further arranged that in addition to the central Committee of the Council above mentioned, the Society's Branches at Toronto and Ottawa should be asked to formulate the programmes in these cities and be responsible for the completion of the same. In Ottawa the departmental officials were to take in hand, especially, the organization of the banquet to be tendered to the delegates by the Dominion Cabinet.

CANADIAN EXCURSION

June 12th P.M.—Leave Sault Ste. Marie.

June 13th A.M.—Arrive Port McNicoll.
The terminal facilities of this Port will be inspected and a special train will convey the party to Toronto.
P.M.—Arrive Toronto.
The afternoon will be spent in sight-seeing.

June 14th A.M.—A short excursion on the Lake and Harbour.
The Toronto programme will be in charge of a local Committee of the Toronto Branch of the Canadian Society of Civil Engineers.
P.M.—Leave Toronto (by steamer).

June 15th A.M.—Arrive Prescott.
Before reaching Prescott (about 10 A.M.) the Thousand Islands of the St. Lawrence River will have been passed through.
A.M.—Leave Prescott.
P.M.—Arrive Ottawa.
The arrangements at Ottawa will be in charge of a Committee of the Ottawa Branch of the Canadian Society of Civil Engineers. A very interesting programme has been prepared, including a banquet to the gentlemen of the party by the Dominion Cabinet, and some special entertainment for the ladies.

June 16th A.M.—Leave Ottawa (by train).
A.M.—Leave Coteau Landing (by boat).
P.M.—Arrive Montreal.
On this trip the lower lock of the Soulanges Canal will be inspected.
June 17th —At Montreal—Inspection of Harbour and tour of City.
June 18th A.M.—Leave Montreal by Government Steamer.
P.M.—Arrive Quebec.

The Council at a subsequent meeting appointed Professor McLeod as the representative of the Society to the Congress in Philadelphia, in order chiefly that he might have an opportunity of ascertaining the names and becoming acquainted with those members who desired to visit Canada and of organising the various features of the excursion in Canada.

Immediately on the adoption of the programme, transportation arrangements were made with the C. P. Ry. Co., the R. & O. Navigation Company and the G. T. Ry. and with the Department of Marine and Fisheries for the use of a special steamer from Montreal to Quebec, and the necessary hotel accommodation was reserved at Toronto, Ottawa, Montreal and Quebec. The following is the list of those who registered at Philadelphia for the Canadian Excursion.

Representing the Argentine Republic

Mr. Figueroa, O., Civil Engineer, London, Government Delegate.

Representing Belgium

Mr. Vander Vin, H., Chief Engineer of Bridges and Roads, Antwerp, Government Delegate.
Mr. Bogaert, M., Engineer, Brussels.
Mr. Bonnel, J., Builder, Brussels.
Mr. Bosquet, Albert, Brussels.
Mr. Bosquet, J., Brussels.
Mr. Cleuren, G., Brussels.
Mr. Colin, E., Brussels.
Mr. Colin, E., Jr., Brussels.
Mr. de Beukelaer, F., Merchant, Brussels.
Mr. de Koninck, L., Brussels.
Mr. Delbove, L., Brussels.
Mr. de Meulenaere, O., Brussels.
Mr. Dillies, C., Manufacturer, Brussels.
Mr. Fichelin, G., Brussels.
Mr. Medaets, A., Contractor of Public Works, Brussels.
Mr. Mertens, Chas., Clerk of Bridges, etc., Brussels.
Mr. Piron, Expert, Brussels.
Mr. Van der Houte, J. F., Contractor.
Mr. Vandeuren, J., Contractor, Brussels.
Mr. Verganwen, Brussels.

Representing Brazil

Dr. M. E. de Souza Bandeira, Government Delegate.
Miss Marie de Souza Bandeira.

Representing Canada

Lt.-Col. Anderson, W. P., Chief Engineer, Dept. of Marine, Ottawa, Government Delegate.
Mr. Lamb, H. J., Engineer of Public Works, Windsor, Government Delegate.
Mr. McLeod, C. H., Professor, Montreal, Corporation Delegate.
Mr. de Bray, Dr. of Science, Montreal.
Mrs. Anderson, Ottawa.
Mrs. de Bray, Montreal.

Representing Cuba

Mr. Guastella, S., Chief Engineer, Havana, Corporation Delegate.

Representing Denmark

Mr. Hummel, C. M., Chief Marine Engineer, Copenhagen, Government Delegate.
Mr. Schonweller, G., Prof. i. Wasserbau, Copenhagen.

Representing Egypt

Mr. d'Epantchine, N., Engineer, Cairo.

Representing France.

Mr. Chargueraud, State Councillor, General Inspector of Bridges and Roads, Paris, Government Delegate.
Mr. de Joly, G., Chief Engineer of Bridges and Roads, Paris, Government Delegate.
Mr. Barrillon, P., Engineer of Bridges and Roads, Bordeaux, Government Delegate.
Mr. Bouvaist, General Inspector of Bridges and Roads, Government Delegate.
Mr. de Pulligny, Chief Engineer of Bridges and Roads, New York, U.S., Government Delegate.
Mr. Voisin, J., Chief Engineer of Bridges and Roads, Boulogne sur Mer, Government Delegate.
Mr. Batard-Razeliere, A., Chief Engineer of Bridges and Roads, Marseilles, Government Delegate.
Mr. Ducrocq, Chief Engineer of Bridges and Roads, Le Havre, Government Delegate.
Mr. Dreyfus, S., Chief Engineer of Bridges and Roads, Paris, Government Delegate.
Mr. Le Trocquer, Engineer of Bridges and Roads, Paris, Government Delegate.
Mr. Perrier, L. C., Chief Engineer of Bridges and Roads, Ismailia, Egypt, Government Delegate.
Mr. Farjon, F., President, Chamber of Commerce, Boulogne sur Mer, Government Delegate.
Mr. Brancher, A., Engineer, Paris.
Mr. Narcy, P. J., Notary, Le Havre.
Mrs. Voisin, Boulogne sur Mer.

Representing Germany

Dr. Freiherr von Coels von der Brugghen, Under Secretary of State, Public Works Dept., Berlin, Government Delegate.
Mr. Lusensky, F., Ministerial Director for Trade and Commerce, Berlin, Government Delegate.
Mr. Tincauzer, E., "Geheimer Oberbaurat," Public Works Dept., Berlin, Government Delegate.
Mr. Thoholte, R., "Geheimer Baurat," Dept. of Lands and Forests, Berlin, Government Delegate.
Mr. de Thierry, G., "Geheimer Baurat" and Professor, Berlin, Government Delegate.
Mr. Hedde, P., Kais. Marine Architect, Berlin, Government Delegate.
Mr. von Haag, Ph., Ministerial Director, Dept. of the Interior, Stuttgart, Government Delegate.
Mr. Ehlers, P., Member of Board of Works and Professor, Danzig, Government Delegate.
Mr. Schulze, F. W. O., Professor, Danzig, Government Delegate.
Mr. Wulle, K., Government Architect, Dirschau, Government Delegate.
Mr. Frentzen, K., Government Architect, Dorsten (Lippe), Government Delegate.
Mr. Gugenham, M., "Oberbaurat," Stuttgart, Government Delegate.
Mr. Mayburg, Government Architect, Dusseldorf, Government Delegate.
Mr. Apelt, President, Chamber of Commerce, Bremen, Corporation Delegate.
Mr. Hoffmann, A., Editor, Leipzig, Corporation Delegate.

Report of the Annual Meeting of the Canadian Society of Civil Engineers, held in Montreal, Jan. 28, 29, 30, 1913

Mr. Schmidt, G. H., Harbour Director, Dortmund, Corporation Delegate.
Mr. Brinzinger, A., Architect, Esslingen.
Mr. Bueren, H., Merchant, Munster.
Mr. Ebelt, O., Government Architect, Essen-Ruhr.
Mr. Heiser, B., Government Architect, Pillau-Konigsberg.
Mr. Jungel, J., Government Assessor, Stuttgart.
Mr. Landsberg, G., Government Architect, Berlin
Mr. Lehmann, F., Member Municipal Board of Works, Osnabruck.
Mr. Lisse, L., "K. Bergassessor," Charlottenburg.
Mr. Lobbecke, E., Doctor of Law, Hildesheim.
Mr. Meck, B., Manufacturer, Nurnberg.
Mr. Schinkel, M., Government Architect, Kiel.
Mr. Speer, T., Assessor, Heilbronn.
Dr. Zimmerman, E. W., New York.
Mrs. Else Landsberg, Berlin.
Mrs. Schmidt, G., Dortmund.
Mrs. Thoholte, Berlin-Steglitz.

REPRESENTING GREAT BRITAIN

Lt.-Col. Yorke, H. A., R.E., C.B., London.
Mrs. H. A. Yorke, London.

REPRESENTING HUNGARY

Mr. de Kohanyi, Z., Chief Marine Inspector, Budapest, Government Delegate.
Mr. Posa, Chas., Technical Adviser, Budapest, Government Delegate.
Mr. de Szabo, N., Chief Engineer, Budapest, Government Delegate.

REPRESENTING ITALY

Mr. Sandjust di Teulada, E., Chief Civil Eng. Inspector, Rome. Government Delegate.
Mr. Luiggi, L., Chief Civil Eng. Inspector, Rome, Government Delegate
Mr. Valentini, C., Chief Civil Engineer, Bologna, Government Delegate.
Mr. Dondonna, Ph.. Naval Captain, Pittsburgh, U.S., Government Delegate.
Mr. Brunati, P., Engineer, Milan.
Mr. Castiglioni, C., Engineer, Milan.
Mr. de Chantal, E., Engineer, Venice.
Mr. Fontana, P., Engineer, Milan.
Mr. Gullini, A., Engineer, Rome.
Mr. Pain, A., Engineer, Venice.
Mr. Rava, G., Engineer, Venice.
Mr. Allegri, M., Army Doctor, Venice, Corporation Delegate.
Mr. Vianello, F., Naval Captain, Venice.
Mrs. Allegri, Venice.

REPRESENTING MEXICO

Mr. Mateos, J., Mexican Consul, Port Arthur, Texas, Government Delegate.

REPRESENTING NORWAY

Mr. Kristensen, I., Director of Maritime Works, Kristiania, Government Delegate.
Mr. Johnsen, J. P., Kristiania.

REPRESENTING ROUMANIA

Mr. Botez, E., Naval Captain, Soulina.

REPRESENTING RUSSIA

Mr. de Timonoff, V. E., Engr., State Councillor, St. Petersburg, Government Delegate.
Mr. de Hoerschelmann, E. F., Engr., State Councillor, Tsarskoie Selo Government Delegate.
Mr. Merczyng, C. K., Engr., State Councillor, St. Petersburg, Government Delegate.
Mr. Tsionglinsky, M. F., Engr., State Councillor, St. Petersburg Government Delegate.
Mr. de Rummel, L., State Councillor, Reval, Government Delegate.
Mr. Olkhine, A. S., State Councillor, Director of Commerce, Government Delegate.
Mr. Ivanovsky, A. V., Engineer, Government Delegate.
Mr. Bakhmetief, J. A., State Councillor, Government Delegate.
Mr. Rojdestvensky, A. K., Engineer, Government Delegate.
Mr. Chovgenoff, Court Councillor, Government Delegate.
Mr. Kortschynsky, Engineer, Moscow.
Mr. Laknisky, V. E., Engineer, St. Petersburg.
Mr. Martinowsky, M., Engineer, Cherson.
Mr. Schmakoff, W., Moscow.
Mr. Zwetaieff, Moscow.
Miss Kortschynsky, Moscow.

REPRESENTING SWITZERLAND

Mr. Hilgard, K. S., Prof. Consulting Engineer, Zurich. Corporation Delegate.

REPRESENTING THE UNITED STATES

Lt.-Col. Sanford, J. C., Corps of Engineers, Philadelphia, Government Delegate.
Col. White, H. K., U.S. Marine Corps, Southport.
Mrs. J. C. Sanford, Philadelphia.
Mrs. H. K. White, Southport.

The meetings of Congress were concluded on May 28th, and a large number of the delegates made a trip to Washington, Pittsburg and other Southern points and returning, one party by way of Hudson River, the other through Cape Cod and Boston, united at Albany whence an excursion was made along the line of the New York State barge canal with stops at Syracuse and Buffalo. At Buffalo, the party, numbering about three hundred, embarked on the steamer "Northland" and visited Cleveland, Detroit and Sault Ste. Marie. At Sault Ste. Marie the Canadian party separated from the other excursionists and began the trip in accordance with the above programme.

The following members of the Canadian Society of Civil Engineers welcomed and took charge of the foreign visitors:—Col. Anderson, Past President of the Society; Dr. J. Galbraith, Past President of the Society; Mr. J. Morkill, Member of Council; Mr. H. J. Lamb, Member; and Mr. C. H. McLeod, Secretary. On account of various unforeseen causes several of the gentlemen, who had booked passage at Philadelphia, were unable to make the Canadian excursion, and it was especially regretted that amongst these was Professor de Timonoff, the President of the Congress. Some time was spent at Sault Ste. Marie examining the locks and shipping facilities on the American and Canadian sides, and the voyage down the Lake and Georgian Bay commenced at 3 P.M., Wednesday, June 12th.

Messrs. J. G. Sing and T. R. Loudon, representing the Toronto Branch of the Canadian Society of Civil Engineers, came to Port McNicol for the purpose of distributing hotel assignments and making other arrangements with the managers of the Excursion. At Toronto the party was welcomed by the Committee of the Toronto Branch of the Society named below, and under their direction the following local programme was carried out in a most successful manner.

TORONTO COMMITTEE

Chairman—T. C. Irving, Jr.
Secretary—T. R. Loudon
G. G. Powell
H. E. T. Haultain

Report of the Annual Meeting of the Canadian Society of Civil Engineers, held in Montreal, Jan. 28, 29, 30, 1913

J. Galbraith
E. T. J. Brandon
Parker Kemble
F. F. Loudley
Allan Garrow
E. L. Cousins
J. G. Sing

The special thanks of the Society are also due to the Mayor of Toronto, Mr. Reginald Geary, to Commodore Aemilius Jarvis of the R.C.Y. Club, and to Mr. L. H. Clarke, Chairman of the Harbour Commissioners. The following gentlemen also contributed in a wholehearted manner toward the success of the visit to Toronto: Messrs. E. L. Cousins, Engineer of the Harbour Board; A. L. Lewis, Secretary of the Harbour Board; J. C. Eaton, whose magnificent yacht was put at the disposal of the visitors; Alderman Alf. Maguire, who was associated with the Mayor in representing the City; Lt.-Col. J. B. Miller, Mr. Carl Allen of the R.C.Y. Club, and others for many courtesies. The ladies of the party were entertained under the direction of the following Committee:

Mrs. Galbraith	Mrs. Cousins
Mrs. Kemble	Mrs. Loudon
Mrs. Sing	

TORONTO PROGRAMME

"Special train is due to arrive Toronto about 1.15. Party will detrain at North Parkdale station, and take special street cars waiting on Dufferin Street which will run direct to King Edward Hotel. Headquarters of the party will be King Edward Hotel.

Tickets will be found herewith showing room assigned to each member of the party. Please present these tickets at King Edward Office for keys.

Baggage will continue by train to Union Station and will be conveyed from there to the hotel. Each piece of baggage should have a tag attached showing room number of owner at King Edward Hotel.

Luncheon will be served at King Edward Hotel at 1 30 and ticket for same will be found herewith

Through the courtesy of the Toronto Board of Harbour Commissioners, and the Commodore and Members of the Royal Canadian Yacht Club, the party will be tendered a trip around Toronto Island. The Royal Canadian Yacht Club's launch leaves the R.C.Y.C's. city station at the extreme end of the East side of Yonge Street dock at 2.45, 3 15 and 3.45, for the R C.Y.C. Club House, Toronto Island where the yachts will be boarded

At 7 o'clock a Dinner will be tendered by the Harbour Commissioners and the Royal Canadian Yacht Club in the Club House, Toronto Island. Dress will be informal.

Friday, June 14th. A breakfast ticket will be found herewith.

At a quarter to ten, through the courtesy of the City Council and a number of Citizens of Toronto, automobiles will be placed at the disposal of the visitors for a ride around the city. The party will leave the King Edward Hotel sharp at 10 o'clock and will proceed to the City Hall, where His Worship, the Mayor, will receive the party in the Council Chamber, after which automobiles will be taken for a drive, visiting points of interest, including the Provincial Parliament Buildings and the University of Toronto. The drive will terminate at McConkey's where a luncheon will be tendered by the City Council.

Richelieu and Ontario Navigation Co's. boat leaves the East side of the foot of Yonge Street sharp at 2.30, and the members of the party should be on board not later than 2 15. All baggage should be ready not later than 12 o'clock noon and each piece should have a ticket showing the number of the owner's stateroom on the R. & O. boat."

Passage was taken from Toronto at 2 30 p.m., on Friday, June 14th, on the S.S. Kingston. It was, unfortunately, necessary for several of the members, on account of their business arrangements and dates of sailing from New York to leave the party at Toronto. Those on board the steamer numbered in all 131 The party landed at Prescott early on Saturday morning, where they were met by Mr. D. MacPherson, Member of Council, representing the Ottawa Branch of the Society. At Ottawa the delegates were received by the following Committee, under whose direction the local programme outlined below was observed.

OTTAWA COMMITTEE

Chairman—S. J. Chapleau
Hon. Secy.-Treas.—H. V. Brayley,
Noulan Cauchon
R. de B. Corriveau
F. J. Delaute
John Murphy
R. F. Uniacke

The Ottawa banquet was given in the new and magnificent Chateau Laurier Hotel and was presided over by Mr. Hazen, Minister of Marine and Fisheries. The following Cabinet Ministers were also present, adding thereby eclat to the occasion.

Col. Hon. Sam Hughes, Minister of Militia and Defence.
Hon. C. J. Doherty, Minister of Justice.
Hon. Martin Burrell, Minister of Agriculture.
Hon. F. D. Monk, Minister of Public Works.
Hon. T. W. Crothers, Minister of Labour.
Hon. G. H. Perley, Minister without portfolio.
Hon. J. A. Lougheed, Minister without portfolio.

OTTAWA PROGRAMME

"The visiting members will arrive at the Central Station at noon. They will be met by representatives of the Ottawa Branch, Canadian Society of Civil Engineers.

Informal Lunch will be served at the Chateau Laurier.

During the afternoon, automobiles will convey the party, accompanied by members and ladies of the Ottawa Branch, through picturesque Ottawa, and the following itinerary, so far as possible, will be followed:—

2.15 P.M.—Leave Chateau Laurier for Parliament Hill. Attention is directed to: (1) The Locks of the Rideau Canal, built in the year 1832, overcoming the 80 feet difference in levels between the Ottawa River and the Rideau Canal, (2) the Limestone face of Major Hill Park, along which the C.P.R. line approaches, (3) the Interprovincial Bridge crossing the Ottawa River and connecting the Provinces of Ontario and Quebec, (4) the City of Hull with (5) the Laurentian Hills in the background, (6) the Chaudiere Falls and (7) the Timber Slides.

2.30—3.00 P.M.—Thirty minutes will be devoted to an inspection of the Parliament Buildings, including the Parliamentary Library, the Senate Chamber and the House of Commons. The Corner Stone of these buildings was laid in 1860, by the Prince of Wales, who afterwards became King Edward VII., and the buildings were completed about 1866.

3.00—3.30 P.M.—From Parliament Hill a visit will be made to Rockcliffe Park, passing through Rideau Hall grounds, the official residence of His Royal Highness the Duke of Connaught, Governor-General of Canada.

3.30—4.10 P.M.—From Rockcliffe Park to the Dominion Government Experimental Farm via the Driveway.

4.10—4.40 P.M.—Inspection of the Dominion Government Experimental Farm and the Astronomical Observatory.

5 00—5.40 P.M.—From the Experimental Farm the drive will be continued to the Chaudiere Falls on the Ottawa River. Inspection of the Water Power Dam controlling 50,000 horse-power will be made, also the Hydraulic Power Plants, Electric Stations, Saw Mills, Pulp and Paper Mills.

Report of the Annual Meeting of the Canadian Society of Civil Engineers, held in Montreal, Jan. 28, 29, 30, 1913

6.00 P.M.—The return trip will be through the City of Hull in the Province of Quebec, and over the Interprovincial Bridge. Attention is again directed to the view from the bridge of the Parliament Buildings, Chaudiere Falls and the lower Ottawa River.

In the evening at eight o'clock, the members of the International Congress of Navigation will be tendered a dinner at the Chateau Laurier by the Government of Canada. At the same hour the ladies, accompanying the members of the International Congress of Navigation, will be tendered a dinner at the Chateau Laurier by Mrs. R. L. Borden, and the wives of the Members of the Government of Canada."

Mrs. R. L. Borden very kindly received and presided over the entertainment of the ladies of the party in Ottawa.

A special steamer through the Coteau and Cedar rapids afforded opportunities for seeing the navigation of the rapids, and the party was enabled to inspect the lower portions of the Soulanges Canal.

At Montreal, which was reached on Sunday evening June 16th, the excursionists were met by a Committee of the Council of the Society and conducted to the Place Viger Hotel. The following local programme was observed in Montreal, and opportunities given for inspection of the city and especially of the shipping facilities of the harbour of Montreal were greatly appreciated by the visitors.

MONTREAL PROGRAMME

FOR MEN

9.00—10.30 A.M.—Drive on Mount Royal, to terminate at Wharf for Harbour Commissioners' excursion.

10.30 A.M.-1.00 P.M.—Excursion on Harbour. Landing to be made at Wharf adjacent to Place Viger Hotel. Lunch at Hotel privately.

3.00 P.M.—6.00 P.M.—(a) Visit to Angus Shops by street cars, or (b) Automobile drives to various points.

Provision will be made for persons who desire to visit the Universities or other places in which they are specially interested.

8.00 P.M.—Complimentary dinner by the Harbour Commissioners at Montreal Club, Dominion Express Building, St. James Street.

FOR LADIES

10.00 A.M.—Drive on Mountain.

1.00 P.M.—Luncheon by Ladies' Committee at Windsor Hotel.

3.00 P.M.—6.00 P.M.—Automobile drive. Dinner at Forest and Stream Club.

June 18th 9.00 A.M.—Board Government steamers Lady Grey and Sir Hugh Allan for Quebec."

The banquet by the Chairman and his associates of the Harbour Commission was an important occasion and these gentlemen deserve the heartiest congratulations and thanks for their assistance in entertaining the guests.

On Tuesday morning, the greater portion of the party, accompanied by a number of Montreal gentlemen and ladies, embarked on the Government steamer "Lady Grey" for the trip down the river. The remainder of the party took passage as the special guests of the Montreal Harbour Commissioners on the steamer "Sir Hugh Allan." The trip down the river was in every way a successful one and the party was safely landed at Quebec in the early evening and conducted to the Chateau Frontenac Hotel. On Wednesday an unofficial programme was observed in Quebec with the assistance of members of the Society resident there.

It was in a large measure [illegible] courteous and substantial assistance given by the Corporation and Associations [illegible] in the foregoing and to the efficient co-operation of the other [illegible] of this Society that the visit of this important body of [illegible] to Canada was so successfully carried out. The [illegible] made to the entertainment of our guests material[illegible] necessary expenditure on Government account and made it possible to carry out the enterprise within the amount of the grant.

On behalf of the Society,

C. H. McLEOD

Montreal, August 1st, 1912

The foregoing Report was transmitted to the Honourable Minister of Marine and Fisheries on November 1st last in accordance with instructions of the Council and was acknowledged as follows:

Ottawa, November 5th, 1912

Sir,—

I [illegible] acknowledge the receipt of your letter of the 1st instant, covering your very interesting report on the excursion of members of the twelfth International Congress of Navigation through Canada in June last.

From it as well as from reports received from Col. Anderson, Government Delegate from the Department, I learn of the great assistance rendered to the Government by the Canadian Society of Civil Engineers, and I would now ask you to convey to the Council of the Society my sincere acknowledgment of and the thanks of the Government of Canada for the valuable services rendered gratuitously by your Society by the several local branches and by yourself as Secretary, and which contributed in so great a degree in making the Canadian excursion a very signal success.

Yours sincerely

(Signed) J. D. Hazen.

Prof. C. H. McLeod,
Sec. Can. Soc. Civil Engineers,
Montreal, P.Q.

SUBWAY AND BRIDGE COSTS.

A reinforced concrete highway bridge spanning two railway tracks, waterproofed, paved with vitrified brick and designed for a moving weight of 100 lbs. per square ft. of floor area, or a 10-ton road roller, can be built for $1.65 per sq. ft. of floor, including the spans, supports and ordinary foundations, according to a statement made by H. N. Rodenbaugh, assistant engineer, Southern Railway, Atlanta, Ga., in a paper read before the Engineering Association of the South. Such a structure is only slightly higher in first cost than the typical steel girder bridge of similar capacity with a wooden floor, which costs about $1.50 per sq. ft. of floor area complete. A very satisfactory wooden Howe truss bridge of modern design has been built by one railway at a total cost of $45 per sq. ft. of floor area, and as between the latter two structures, Mr. Rodenbaugh very much favors the wooden bridge. Commenting on shallow floors, which are very common in subway design, he states that a typical open floor—that is, one having ties resting on steel stringers without ballast—will have a depth from base of rail to under clearance of about 3 ft. 4 in., and will cost about $1.20 per sq. ft. of floor area. A transverse steel I-beam construction with ballasted deck on flat plates will have for the same span a depth of 3 ft. 1 in., and will cost about $1.90 per sq. ft. of floor area.

Report of the Annual Meeting of the Canadian Society of Civil Engineers, held in Montreal, Jan. 28, 29, 30, 1913

NEW INTAKE PIPE, OTTAWA, ONT.

By L. McLaren Hunter.*

A new intake pipe was necessary to supply water to Ottawa, owing to the condition of the old pipe which, after the last typhoid epidemic, was investigated, thoroughly examined, and proved to be in a very leaky condition.

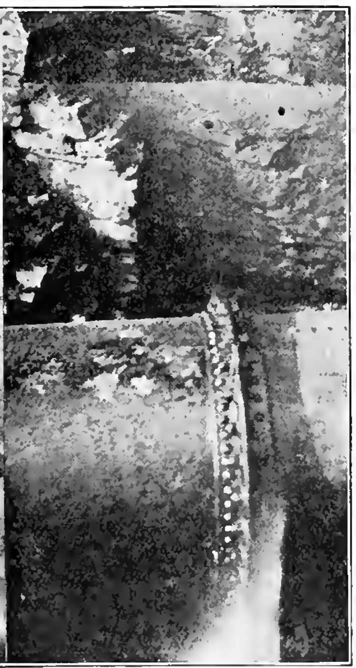
Tenders were called and the contract was awarded to Messrs. Laurin and Leitch, of Montreal, who contracted to finish the aqueduct section of the intake by December 1st, 1912. The council offered a bonus of $200 for every day that the pipe was completed before the specified day for completion, and a fine of $200 for every day over the specified date.

The new intake is a forty-two-inch lock-bar steel pipe, one-quarter inch thick, made by the East Jersey Pipe Company, of Paterson, New Jersey. The length of the intake is twenty-four hundred feet

In connection with the pipe, three twelve-million Imperial gallons per day, electrically driven pumps of the Rees Roturbo type, and run by Canadian General Electric motors, were placed at Lemieux Island—the mouth of the intake. These pumps have a lift of twelve feet, thus throwing the whole line of the 42-inch steel pipe, supplying the city, under a head of water sufficient to insure the pressure being outwards all along the pipe line.

The pipe thus far has proved very satisfactory, and during the hydraulic test withstood the guaranteed pressure without a leak being noticed.

Pipe Entering Tunnel of Aqueduct.



Detail Photograph of Joint Between Old and New Intake.

The construction of the pipe was in the charge of Mr. William Storrie, A.M.Inst.C.E., and was carried out in a very expeditious manner, the contract being let on October 2nd, 1912, and completed by November 21st. The city was being supplied with water through it on the 27th of the same month.

* Of the City Engineer's Department, Ottawa.

TIN PLATE PRODUCTION AND CANADA.

During 1912 the United States have largely extended their exports, and Britain has been meeting their serious competition in neutral markets, such as Canada and Japan, state Messrs. Sims and Coventry, in their report on the tinplate market during 1912. British exports to the former country are considerably smaller than they were some years ago and so long as the American makers choose to supply the Canadians with tinplates regardless of whether it pays them or not they will no doubt secure the business. The Canadians are getting the benefit and the Americans seem satisfied with the "honor and glory." At the time of writing there are no exact figures available as to the American output for the year, but as the American mills have been running much more fully during the year there is sure to be a considerable increase over 1911 and there is little doubt that their make will have exceeded that of Britain. In the last report a doubt was suggested as to the American foreign trade being on an economically sound basis.

Joining of the Old Intake and the New One.

New 42-inch Steel Pipe in Aqueduct.

Germany lays claim to having been the original home of the tinplate industry, having, so it is said, begun the manufacture in the fourteenth century. They are now turning out some 50/60,000 tons a year, the figures for three years at intervals of ten being:—

	Tons. 1890.	Tons. 1900.	Tons. 1910.
German manufacture	21,300	30,705	57,136
Imports into Germany	4,296	18,158	46,973

It will be noticed that the imports are increasing more quickly than the home production and a proposal for a considerable extension of the German manufacture has received powerful advocacy. At one time (in the nineties) the German makers supplied 96 per cent. of their home consumption, whereas in 1910 it was only 55 per cent. In 1907 it fell as low as 51 per cent. Now, the advocates of German extension look forward to making a bid for the export trade, and a number of new mills are already at work in Westphalia. The American manufacture has increased by rapid steps. In 1910 their output was 722,770 tons. British exports in that year of tinplates, terneplate and blackplate for tinning were 538,870 tons, and if Britains export trade takes about two-thirds of British make, this would give 808,305 tons as Britains total ouptut for 1910. In 1911, the American make was 783,360 tons and on the same method of computation Britains was 816,630.

CONTENTS OF THIS ISSUE.

A NATIONAL ENGINEERING SERVICE.

In these columns, in the issue of January 23rd, we published an editorial on "A National Engineering Service." In another part of the same issue were published two articles which had secured the prizes offered in the competition held under the auspices of the Royal Military College Club and the Canadian Society of Civil Engineers.

We inadvertently stated in that editorial that Mr. T. Chase Casgrain, chairman of the International Joint Commission, had offered the prizes for these essays on the formation of a National Engineering Service. Our attention has been drawn to the error by Mr. Casgrain.

Mr. Charles A. Magrath, and not Mr. Casgrain, was responsible for the offering of the prizes in this competition, and we are extremely sorry that the error should have occurred in our previous editorial. The fact that they are both members of the International Joint Commission was the reason for the mistake. The fact that Mr. Magrath has interested himself in the discussion of the formation of a National Engineering Service is sufficient to convince those who know him that some result will be achieved. As a member of the engineering profession in the past, his work has always been marked by accuracy and efficiency, and it is, no doubt, due to his intimate knowledge of the profession that he has appreciated more fully the necessity for a change in the method of administration of engineering service for the federal government. This move on the part of Mr. Magrath is but the forerunner of some plan of concentration and co-operation in the government service.

The matter was discussed at the annual meeting of the Canadian Society of Civil Engineers, held in Montreal last week, and, while no decision was arrived at, it is plain to see that the feeling of the members is strongly in favor of some such system as is outlined in the two essays by Evolu and Observer, printed in the issue of January 23rd.

We would again express our regret that Mr. Magrath was not given the credit for initiating this movement and that the error of ascribing it to another man occurred.

LIABILITY OF CANADIAN RAILWAYS

During the year ended June 30th, 1912, $21,251,664 was added to the stock liability of Canadian railways and $38,996,661 on account of funded debt, representing a total addition of $60,248,325. That increase over the figures of 1911 brought the total capital liability of Canadian railroads up to $1,588,937,526. These figures in themselves are of interest, but more so because considerable railroad construction has yet to be undertaken in the Dominion. The railroad stocks last year totalled $770,459,351 and the funded debt $818,478,175, so that stocks and bonds are about equally divided. It is interesting also to examine the division of the funded debt. This is set forth in the excellent volume of railway statistics compiled by Mr. J. L. Payne, Comptroller of Statistics of the Department of Railways and Canals, at Ottawa. The figures are as follow:—

Funded debt.	1912.
Bonds	$772,532,108
Miscellaneous obligations	12,608,718
Income bonds	17,119,466
Equipment trust obligations	16,217,883
	$818,478,175

The constant call of the Canadian roads for new equipment is reflected in the equipment trust obligations for the past few years. The amount for 1910, 1911 and 1912 exceeded $42,000,000. The Grand Trunk Railway for the first time adopted this form of financing last year.

Mr. Payne calculates the capitalization per mile of our railways. If the total capital liability of $1,588,937,526, as given above, be divided, he says, by the 26,727 miles of operating line shown on a preceding page, the result would be $59,454 per mile of line. It would be quite misleading, however, to make such a calculation. Neither the divisor nor the dividend is correct. The mileage, for example, includes Government owned and operated lines, to which no capital liability attaches. On the other hand, the capital figures embrace the liability of unfinished lines, such as the Grand Trunk Pacific, which do not appear in the mileage column. The deductions under this head amount to $134,321,020. Then there is considerable duplication. It has not been practicable to ascertain the exact amount thereof, created chiefly by the issue of stocks and bonds for the purchase or control of smaller roads by the larger, but it is known to be not less than $210,000,000. Joining these two sums, and subtracting the total from the $1,588,937,526 already indicated, the remainder is $1,244,616,506. For immediate statistical purposes that might be regarded as the proper capital liability of Canadian railways.

The elimination of Government owned lines, and such other lines as should not figure in the mileage column, reduces the total to 24,485. Using these factors, it will be seen that the capital liability of railways in Canada amounts to $50,832 per mile. This is a relatively low figure.

The net capitalization per mile of line in other countries is as follows:—

Country.	Net capital per mile.
United States	$ 59,345
United Kingdom	275,166
France	94,933
Germany	111,737

The cost per mile of the government owned railways in Canada has varied considerably. The Intercolonial with 1,463 miles of line has a cost per mile of $64,761; the Temiskaming and Northern Ontario Railway, $58,495; the Prince Edward Island, $32,296; and the New Brunswick Coal and Railway, $33,398.

The capital liability of Canadian railways has grown enormously in the past few decades. In 1876 railway stocks totalled $181,000,000 and the funded debt $76,000,000, an aggregate of $257,000,000. In 1900 the stock indebtedness had expanded to $410,000,000 and funded debt to $373,000,000, a total of $784,000,000. In 1908 the funded debt for the first time exceeded the stocks, the figures being respectively $631,000,000 and $607,000,000, or a total sum of $1,238,000,000. Last year, as mentioned above, the stocks had reached $770,000,000 and funded debt $818,000,000. The growth in stocks since 1876 has been $589,000,000, or 325.4 per cent.; in funded debt $742,000,000, or 976.3 per cent.; in total capital liability $1,331,000,000, or 517.9 per cent.

The relationship of dividends and net earnings to share capital have shown some interesting fluctuations during recent years. In 1907, the percentage of dividends paid to share capital was 2.17, and this percentage changed year by year as follows: 1908, 2.11 per cent.; 1909, 2.97; 1910, 3.16; 1911, 4.08; 1912, 4.04. The percentage of net earnings to share capital in 1907 was 7.30. In 1908 it declined to 6.51, and in the following year to 6.24. In 1910 it increased to 7.78 per cent.; next year it declined to 7.70 and last year rose to 8.91. Of the total dividends paid in 1912 amounting to $31,164,791; on common stock, $18,487,000 was paid; and $12,677,791 on preferred stock.

LETTER TO THE EDITOR.

Sir.—We notice on page 901 of your issue for December 19th, 1912, that the Stereophagus Pump and Engineering Company, Limited, control the Canadian rights of the Hon. R. C. Parson's pump. Permit us to point out that this is liable to give a wrong impression, as we made the earliest pumps and hold the license for this pump in every part of the world. We are, therefore, in a position to supply to Canada.

Yours faithfully,

THE PULSOMETER ENGINEERING CO., Limited.

Reading, England, January 21st, 1913.

MONTREAL'S BOARD OF TRADE

The annual meeting of the Montreal Board of Trade brought out some remarks by the retiring president, Mr. Robt. W. Reford, on a point of much economic interest and importance. He referred to the selling to industries on the other side of the international boundary line of power generated in Canada. He questioned whether it was wise to permit the export of power developed near Montreal as the growth of the city depended to such an extent upon cheap power. He also regretted the failure of the provincial government to appoint a hydro-electric commission for the purpose of fixing electric power rates. He asked the members of the board to consider whether the manufacturers were not paying too much for power by generating it by steam when a great heritage in water power lay at the very doors. He said that notwithstanding all the water power at the doors of the city the companies which had acquired he powers had been selling the power out at a price apparently governed by the cost of power when generated by coal.

Mr. Reford also referred to the high cost of living, saying that one of the factors was the permission enjoyed by the public utility companies to issue as much capital as they saw fit or as they had prospective power to pay dividends upon at the rate of five or six per cent. All this was increasing the cost of living. Cheap electrical power, cheap transportation and other public utility services would place the manufacturers in a better position to compete and to pay higher wages. After all the capitalizing and re-capitalizing had taken place, the stock eventually found its way into the hands of shareholders who would be the sufferers when the power to charge high rates was curbed. Meantime, the promoters were left to enjoy their illegitimate profits without any interference whatever.

The British Columbia Electric Railway Company plans the construction of additional repair and car-making shops in Burnaby municipality, in addition to the shops they already have at New Westminster. The shops will employ about 500 men.

The new line to Eburne over Oak Street is now in operation. This line runs directly south from Broadway to the Fraser River, Oak Street being five blocks east of Granville. The ultimate plan is to have a double track down Granville to Eburne, when a belt line will be run around Oak, Broadway, Granville and Eburne.

THE MOUNT ROYAL TUNNEL OF THE CANADIAN NORTHERN RAILWAY.

Headings aggregating over a mile in length have already been driven for the Mount Royal Tunnel of the Canadian Northern Railway. A summary of the general scheme and the construction methods was given on page 812 of The Canadian Engineer for January 16, 1913, and the reader is requested to turn to that article, as the points brought out therein need not be repeated.

In view of the rapid progress made since Chief Engineer Brown prepared his excellent paper for the Canadian Railway Club, some photographs and additional notes regarding the work may be of interest.

Four headings are being driven simultaneously—one eastward from the West Portal, one westward from the Dorchester shaft, and one each way from the Maplewood shaft. All four are bottom centre headings. The headings have advanced approximately two thousand feet from the West Portal, sixteen hundred feet from the Dorchester shaft, and a thousand feet each way from the Maplewood shaft. A temporary heading has also been driven eastward from Dorchester shaft nearly to Lagauchetiere Street.

The approach to the West Portal is through a cut about a half mile in length and twenty feet deep at the portal. This cut is through the Model City and will be bridged at the street crossings. Just west of the portal it passes under the Canadian Pacific Railway tracks. Fig. 2, looking west through the site of the Model City, shows the steam shovel making the cut. Fig. 3 shows the West Portal. The compressor house, repair shop, etc., are in the background.

Fig. 4 is a photograph taken from a high cliff on the mountain showing the location of the Maplewood shaft, which is about a mile east of the West Portal and about two and a fifth miles west of the Dorchester shaft. This shaft is almost exactly at the centre of the photograph. The Maplewood shaft is 250 feet deep, the Dorchester shaft 55 feet deep.

Fig. 2.—Steam Shovel Making the Cut at the West Portal

Illustration No. 5 was obtained while the Dorchester shaft was being sunk. The Dorchester shaft is so named because it is immediately alongside of Dorchester Street, almost opposite the old headquarters of the Canadian Society of Civil Engineers. The Maplewood shaft is near Maplewood Avenue, Outremont.

The headings are 9 feet high by 12 feet wide at present. The full size section will be 20 feet high by 28½ feet wide. The work of enlarging to the full size is just being started. Average progress from the Dorchester shaft has been 12 feet a day, although there have been 20 foot days. No shooting is allowed between 11 p.m. and 6 a.m. At the west end, where shooting is allowed at night and stronger blasts possible without public annoyance, the average has been 20 feet per day.

Chief Engineer Brown says that the photograph from which illustration No. 1 was made is one of the best tunnel photographs that he has ever seen. It shows clearly the face of the heading with the four drills mounted on the horizontal bar. Immediately back of the point from which this photograph was obtained, is a large pile of muck from which the laborers shovel off slick sheets into low cars.

Fig. 1.—Face of Leading, Showing Rock Drills Mounted on Horizontal Bar.

Illustration No. 6 shows the cap and post system of timbering which is being used. In his paper before the Railway Club, Engineer Brown said: "The cap and post system is very similar to the segment system, except that the segments are not self-supporting. This system is used in very heavy ground and posts and rakers are used similar to those in the crown bar system. The crown bar system consists of bars (usually of wood) set up parallel to the axis of the tunnel and poling boards driven outside them, almost tangentially to the surface of the tunnel excavation. The crown bars are supported by posts and rakers, so arranged as to best suit the nature of the ground and the methods of excavation and lining.

"The segment timbering system—used in lighter ground—consists of a series of timbers cut in segments, approximately to fit the form of the tunnel cross-section, when set up in a plane vertical to the tunnel axis. The poling boards are driven outside the segments nearly parallel to the axis of the tunnel. The segment timbers are ordinarily self-supporting. This system is often used where only the roof is soft and the segments can be sprung directly from plates on the rock walls"

The Montreal tunnel will not likely require much timbering during construction and as the rock will likely be safe, much of the tunnel may be left permanently unlined. The character of the rock is principally limestone and volcanic in-

trusion. Up to the present time, the headings have gone through Essexite, Trenton limestone and dykes of trap rock, and the engineers expect to strike considerable Nepheline syenite. The engineers do not expect to find any faults in the rock. If they do, they will deal with the emergency as it arises. If they strike water in the headings going up, they will drain it out; if in the headings going down they will pump it out, for which purpose several pumps of the centrifugal type have been provided. They do not expect to strike much water, however.

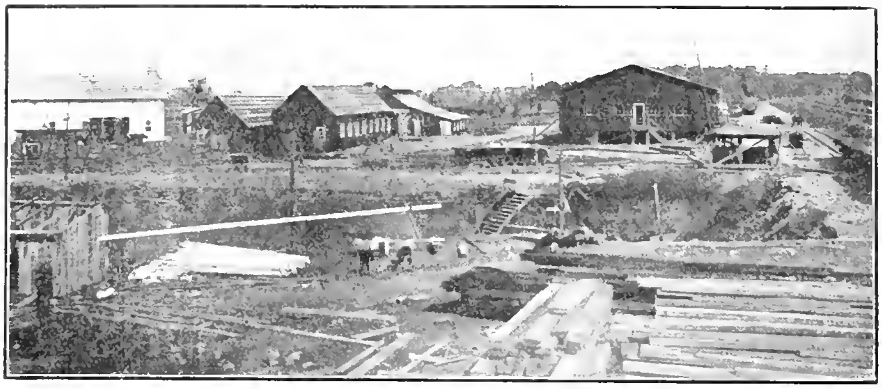

Fig. 3.—Western Approach to the Tunnel.

The tunnel will be lined with concrete. The cement gun method of depositing concrete through pipes with compressed air, like grout, is being investigated, and may be used.

The final designs for the tunnel are not yet decided upon, but it is likely that it will be a twin tube throughout, with a concrete centre wall to facilitate ventilation. In single tube tunnels, where the cross-section is small compared with the bulk of the trains, the piston action of the trains themselves gives excellent ventilation if the portals or openings are free.

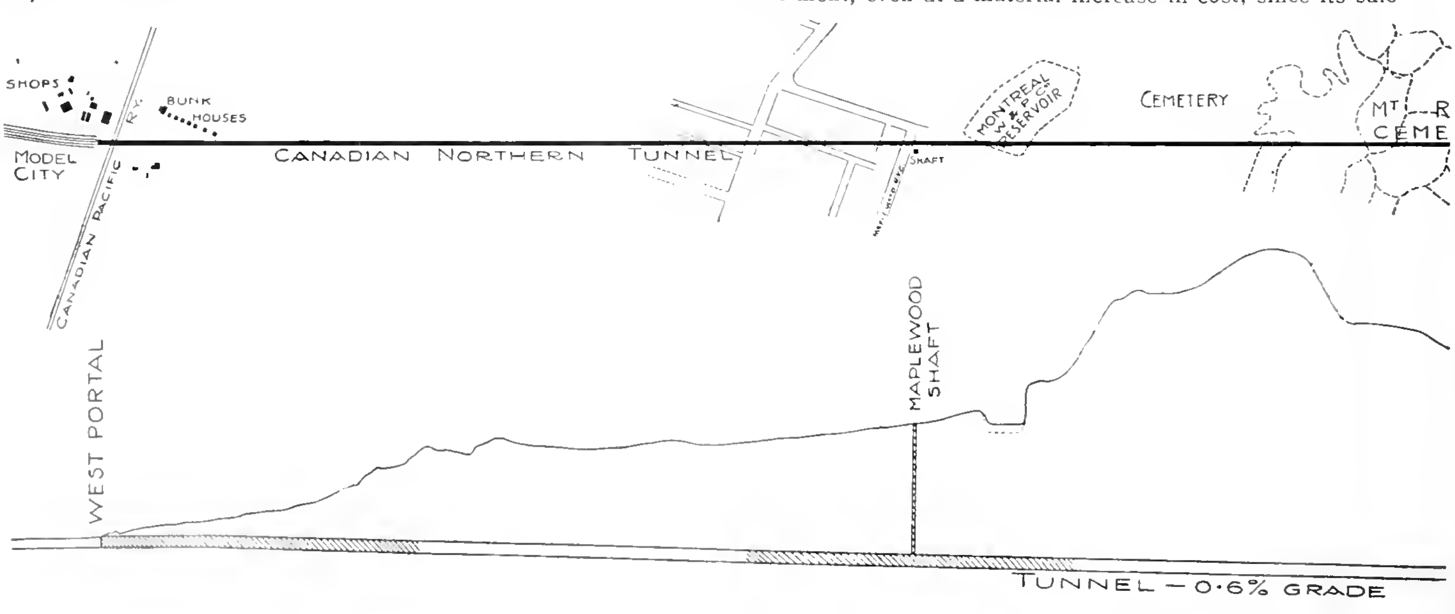
The permanent track in the tunnel will probably be constructed on a concrete base, with creosoted wooden blocks set in the concrete, on which tie plates and screw spikes are used. With this type of construction, a gutter in the centre affords splendid drainage, and the grade and alignment are fixed perfectly. The wooden blocks can be easily removed and renewed. While the engineers favor this type of construction at present, a track laid in rock ballast is also being given consideration and may be used for portions of the tunnel, if not for all of it.

All the very latest signaling devices applicable to this type of tunnel and proven efficient by trial in tunnels in New York City and elsewhere, will be installed in the Mount Royal tunnel. The track will be divided into sections or blocks, the length of which will depend on the grade, curvature, speed and weight of trains, etc.

At the end of the block section an insulated joint is inserted between the ends of the rails, with this type of signal installation. A source of electric current is connected at one end and a track relay at the opposite end, at which end the signal is also installed. The connections are so made that the electric current passes through the rails and relay when there is no train in the block, the relay holding the signal at clear position. When a train enters the block the current takes the path of least resistance through the wheels and axles and is thus cut off from the relay which then allows the signal to fall to "danger" by gravity. If the electric current should fail for any reason, or if the rail should be broken, the signal would go to "danger," just as though a train were occupying the block.

When a block signal is set at "danger" it must be passed, so if only one signal were placed at each block station it would be necessary to approach each signal at a speed which would permit stopping the train at each signal, in case it were found at "danger." To avoid this difficulty, a second signal, called the "distant signal," is installed, which follows the movements of the other, called the "home signal." The distant signal is located so that the train can be easily stopped at the home signal, in case it is in the danger position, as indicated by the distant signal. This signal is usually placed on the same mast with the home signal of the next block, and immediately below it. Within the tunnel lights are substituted for the semaphore arms, the red light being "danger," the yellow for stop position of the distant signal or "caution," and green for the clear, of "proceed" position of both home and distant signals. A safety latch is so placed that if the train runs by a signal set at "danger," the brakes are automatically set and the train stopped.

Engineer Brown is a firm believer in buying good quality of machinery for his plant, as he says it is usually the best investment, even at a material increase in cost, since its sale-



Plan and Profile on the Line of the Mount

able value at the end of the job will be so much greater. Also standard, advertised machinery is easier to dispose of than special equipment. As the plant is only temporary, however, expensive fuel and labor-saving devices cannot usually be installed, as they would not have time to pay for themselves, unless the saving is very large. Duplicate machinery is installed in critical places, so that if a unit gets out of order, the job will nnt be shut down.

Illustration No. 7 shows the compressor house at the

Fig. 4.—Showing Location of the Maplewood Shaft. The Shaft is Almost Exactly at the Centre of the Photograph.

Dorchester shaft. It is duplicated exactly at the West Portal. There are three belt-driven, cross compound compressors, 1,100 cubic-feet per-minute capacity, with induction motors, 225 h.p., 170 r.p.m. These can be seen in the background of the illustration, while in the foreground can be seen parts of a direct-connected, cross compound unit which has since been erected, having a capacity of 2,160 cubic feet per minute, compressing to 100 pounds. This compressor is driven by a synchronous motor, 400 h.p., 170 r.p.m. The power is three-phase, 62½ cycles at 2,200 volts.

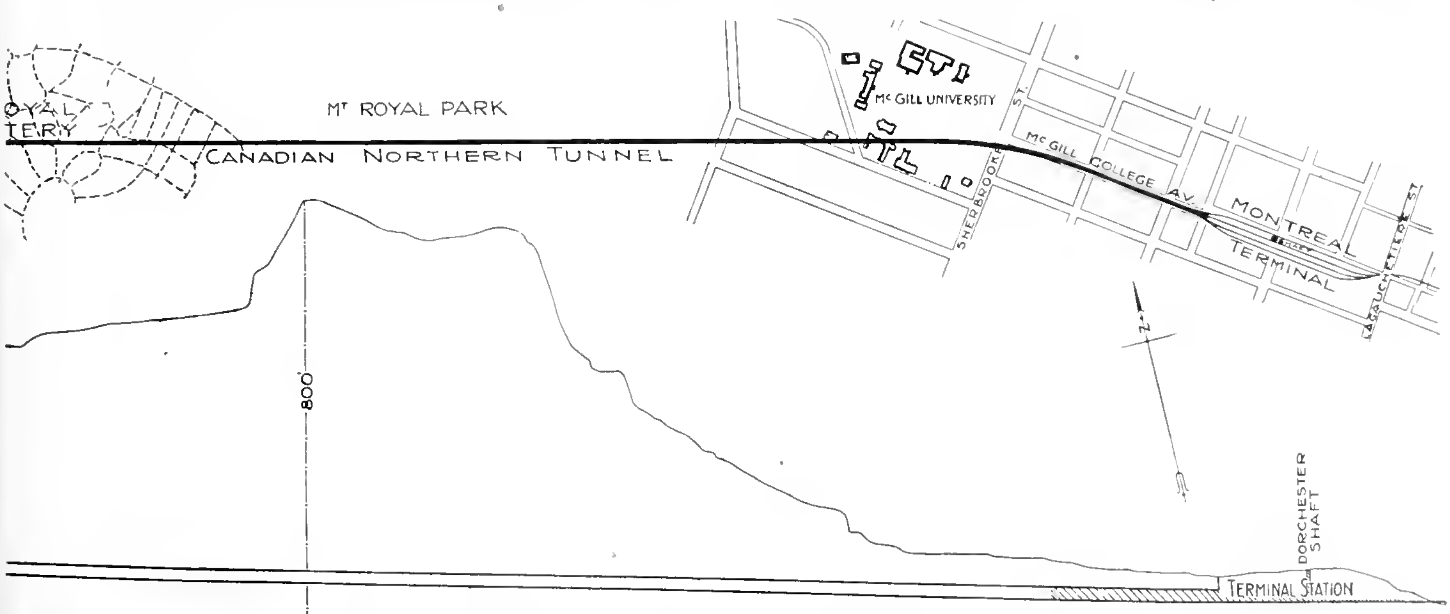
24-inch gauge, V-shaped muck trucks were used at first, but the muck cars now being used are 3-foot gauge, very low and narrow, so that a mucker can shovel into them at maximum efficiency. The wheel base is short. Axle springs reduce the number of derailments resulting from poor track. Gasoline locomotives are used at the West Portal, horses at the Maplewood shaft, and storage battery electric locomotives at the Dorchester shaft. Facilities for recharging the batteries have been provided at the shaft. It is said to be the intention to use storage battery locomotives in the near future at the West Portal and the Maplewood shaft also.

The tunnel is ventilated by forcing fresh air through pipes into the working areas under pressure from blowers driven by motors near the portals. The exhaust from the drills also aids ventilation materially.

Fig. 5.—The Dorchester Shaft.

There is a hospital plant at the West Portal, though its services have been needed but little as yet. Up to the present time the city hospitals have been relied upon in connection with the Dorchester and Maplewood shafts. A well-equipped repair plant has been erected, as even in the city of Montreal, where shops are readily accessible, it was deemed wise to have a complete repair shop on the job, as delays were apt to occur in outside shops over which the tunnel engineers would have no control. As all money spent in tunneling is dead capital until the tunnel is completed, every moment counts, and it was estimated that a few days' delay would cost more than the shop.

Illustration No. 8 shows the engineering corps making precise measurements. Tunnel Engineer Fisher succeeded in throwing a base line directly over the obstacles under which the tunnel passes and in the vertical plane of the tunnel tangent axis. The tapes were calibrated to a standard measure and temperature at a given tension. Readings and measurements were taken independently by each instrument



Royal Tunnel of the Canadian Northern Railway.

man and rod man of the baseline party, and the result summarized by the chief of party to eliminate the personal element.

In this work the tape was anchored at one end to a heavy weight, so that when stretched ahead it passed over a spider with a brass cross hair plate on it. This spider marked the last station measured to. The other end of the tape was attached to a standard weight by a chord passing over a vertical bicycle wheel, thus keeping the tape at the standard tension, and the next measuring spider was set close to this end. The tape was supported at regular intervals and thermometers enabled it to be corrected for temperature. Level readings on the spiders gave the correction for inclination and, as the spiders were set up on transit lines, the final result was a very accurate transverse.

Fig. 6.—Showing Cap and Post Method of Timbering

The baseline was extended down the shafts by plumb lines consisting of heavy weights suspended on piano wire. From these plumb lines the engineer's line was projected into the tunnel. Permanent points and centre line stations were marked by wooden plugs with steel spads.

A visitor to the Mount Royal tunnel is chiefly impressed with the orderliness and absolute lack of confusion with which the work is progressing. Great credit must be given to the four engineers who are chiefly responsible for the work for the swift and precise manner in which the whole undertaking has been handled to date. Although a large gang of men is necessarily being handled (the drills alone requiring about one hundred men, there being three shifts a day, four headings, four drills to the heading, a runner and a helper to each drill), the entire work is excellently regulated. Stephen P. Brown is chief engineer; J. C. K. Stuart, assistant engineer; Howell T. Fisher, tunnel engineer; W. C. Lancaster, mechanical and electrical engineer.

On the line drawing published herewith showing the plan and section of the mountain and tunnel, the shaded portions of the tunnel indicate the progress made in driving the headings. The heading being driven west from the Maplewood shaft will probably meet that being driven east from the West Portal late in the fall of this year. It is estimated that it will take about two years to complete the tunnel. It will be noted that the tunnel curves under McGill University grounds and follows the centre line of McGill College Avenue, as where the covering is light the engineers did not wish to go under a portion of the city where somebody might desire to put up a skyscraper with deep foundations.

The scale to which this drawing was made was one inch to 200 feet horizontally and one inch to 50 feet vertically. The engraving for the illustration was then made about one-seventh the size of the drawing. The straight portion of the tunnel is 76 degrees 33 feet 55 inches N.W.

A few notes concerning the mechanical arrangement of the drills now being used on the work may also be of interest. Essentially the drill is an ordinary rock drill of the reciprocating type with a piston and rifle bar bored out to permit the insertion of a small tube, adjustably secured in the back head of the machine. Water under pressure is conducted by a hose line and fittings to the mouth of this tube, through which a constant jet passes into the pollow piston rod and thence into the hollow drill steel, held in the chuck of the machine. The hole through the drill piston is enlarged for a certain distance from the point at which it ends in the counterbore for the rifle bar, and the function of this opening or secondary counterbore is to connect an impulse of exhaust air from the rear of the piston chamber down through the hole in the piston, when it withdraws from the lower end of the tube, which happens at the instant of reverse on its forward stroke. This action causes a charge of mingled air and water to pass through the hollow drill steel to the cutting face of the bit, which, with the water which passes through when the piston is lifting, has the effect of ejecting the cuttings in the form of sludge from the drill hole. It also insures a clean rock surface for the bit to strike and prevents the hole from mudding up regardless of its direction.

When working under normal conditions, air from the cylinder is not admitted to the hollow piston until after the valve is reversed, with the piston on its forward stroke. The air consumption of the machine is therefore the same as if there were no water tube, because the air which would ordinarily be exhausted by the valve passes through the drill steel, and no live air can be admitted for this purpose.

Fig. 7.—Compressor House.

If, however, the conditions of the ground warrant it, a charge of live air from behind the piston may be directed

into the drill steel, and this will be followed by the impulse of exhaust air as the piston nears the forward end of its stroke. This may be accomplished by pulling the tube farther back into the head and then securing it by screwing down the lock plug upon the rubber sleeve. By thus manipulating the water tube a varying proportion of air and water may be admitted to the drill hole to handle to the best advantage the particular kind of rock that is being drilled.

The water tube is secured in the back head by the rubber sleeve and gland or lock plug just mentioned. Water is introduced through a water elbow and hose fittings, which include a spud, containing a screen to prevent foreign matter from entering the tube, and a screw cap to keep out dirt when

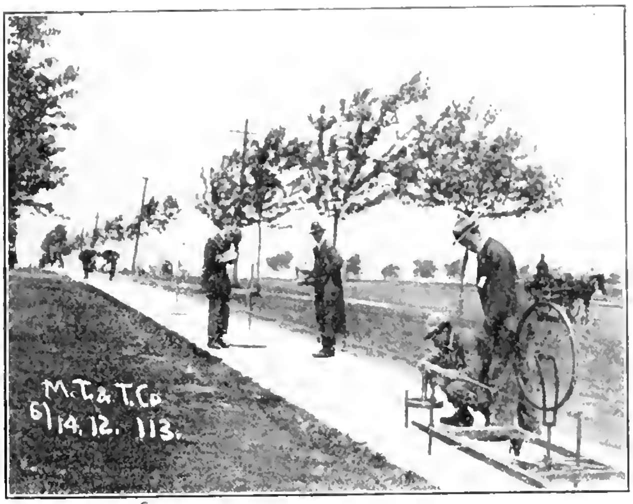


Fig. 8.—Precise Measuring Engineer Corps.

the hose is disconnected. A removable plug is provided to limit the amount of water admitted.

Water under a pressure of from 50 to 100 lb. per square inch is required for clearing the hole of its cuttings. Round, hollow steel is used and requires no shanking. The bit is the regular cross shape similar to that commonly used with solid steel.

The general operation of the drill is the same as that of the ordinary reciprocating or so-called piston machines. The water drills are mounted on horizontal 11-foot heading bars, with a leg or support in the centre to secure stiffness. Four drills are used at once on each bar. When the rock is unusually hard, three double screw mining columns are used instead of the bar. Two drills are mounted on arms on each of the two outside columns, and a fifth drill on the centre column. In one heading the drills have cut as high as 20½ feet per hour per drill. This does not include setting up, but does include changing steel, lining up holes, etc. The average depth of holes is 5½ feet and the average speed per drill hour 16½ feet. In sinking a shaft with 7-foot cut holes and 5-foot line holes, an average of 8.6 feet per hour per drill was maintained (total drilling time). In another heading, where the rock is harder, the four drills cut 13 feet per drill hour, or eighteen 5½-foot holes in two hours.

Application will be made to the Ontario Legislature at its next session for an act amalgamating the North Lanark Railway Company with the Ottawa and St. Lawrence Electric Railway Company under the name of the Ottawa and St. Lawrence Electric Railway Company, and increasing the capital stock from $1,000,000 to $5,000,000 by the creation of 40,000 additional shares of $100 each; and for power to issue bonds and borrow money to the extent of $30,000 per mile of the railway.

INTERNATIONAL ROAD CONGRESS, JUNE, 1913.

Although over six months have still to elapse before the opening of the Road Exhibition in the Royal Horticultural Hall, the preliminary arrangements have all been completed and over half the available stands have been already applied for.

The exhibition will be attended by representatives of highway authorities from all parts of the world. It will be unique in its character, and will bring together for the first time a representative exhibition of road-making materials and appliances, including heavy road machinery.

The organization of the exhibition is in the hands of a committee of which the Right Hon. Earl Beauchamp, K.C.M.G., is president. Other members of the committee are Sir Maurice Fitzmaurice, C.M.G., Colonel R. E. Crompton, C.B., Messrs. Alfred Dryland, Howard Humphreys, T. Richards, Wallace E. Riche, Gibson Thompson, J. Walker Smith, John Willmot and Rees Jeffreys. The honorary secretary is Mr. H. P. Maybury, and the assistant secretary and manager Captain L. A. Kingston.

The exhibition committee is assisted by an advisory committee of traders and exhibitors. The members of this committee are Messrs. H. Pitts (chairman), H. Beadle, H. D. Blake, F. E. Bristowe, E. B. Chittenden, D. G. Comyn, W. Penrose Green, F. W. Manuelle, and H. L. Wettern.

The following table shows the position of the letting of stands at the present time. It is to be regretted that the limitations of space will preclude all the firms who desire to do so from exhibiting.

No. of Stands.	In Hall.	In Machinery Section.
Let	26	7
Under negotiation	14	6
Reserved for foreign exhibitors	10	4
Unlet	16	8
	—	—
Total	66	25
Grand total	—	—91

Among the exhibitors in the Horticultural Hall (for small exhibitors) will be found Messrs. J. and P. Hill-Galloways, Limited; The Anglo-Mexican Petroleum Products Company, Limited; The Limmer Asphalte Company, Limited; Taroads, Limited; The Neuchatel Asphalte Paving Company, Limited; Roadamant, Limited; Tarmac, Limited; The Gas Light and Coke Company, Limited; Rocmac, Limited; Roadite, Limited; The Canadian Mineral Rubber Company, Limited; The Enderby and Stoney Stanton Granite Company, Limited; F. E. Bristowe and Company; Krupka and Jacoby; Ellis and Everard; Iliffe and Sons; J. Hutchinson; Crompton and Company; Good Roads; Roads Improvement Association, and The Surveyor, etc.

The exhibition will be open daily from 9 a.m. to 8 p.m. to members of the congress and their friends, and in view of the fact that the meetings of the congress will take place in close proximity to the hall the exhibition will form a rendezvous for informal discussions. Afternoon tea will be provided at the exhibition for members of the congress immediately after the formal meetings have been concluded.

The executive committee will be glad to welcome any offers of assistance, and at present the matter of laying out the footpath of the exterior section is under consideration. The paths, which are of the width of 12 feet throughout and cover some 750 square yards, could be apportioned in sections to road surfacing and other firms who desire to make a display of their various specialities in paving. Applications for further particulars can be obtained from Mr. W. Rees Jeffreys, honorary secretary, local organizing committee of the

International Road Congress (London, 1913), 72 Queen Anne's Chambers, Westminster, S.W.

MAINTENANCE ENGINEERING IN RAILROAD WORK.*

The chief enemy of the maintenance engineer is water in some form or other. Drainage should not be forgotten in the early stages of an engineering work. Do not dip a road to get under a railway, or a railway to get under a road, without some thought as to the possibility of draining the depression proposed.

In dealing with steel bridge floors there are three courses open to the designer: (1) To make the floor as open as possible, with no place for water to lodge, and every facility for its getting away quickly; (2) to protect the steelwork floor so thoroughly that water cannot get to it; (3) a compromise course. Even the worst drained bridge, however, does not suffer so much as one over a railway, with a floor so designed that steam and gases from locomotives cannot escape freely.

When a structure fails, it is important that a correct diagnosis should be made. Otherwise the treatment may be all wrong, and may lead to large expenditure, when something quite simple and inexpensive would have met the evil equally well.

One instance is recalled where an intelligent inspector, climbing among the girders of a viaduct 140 feet high, found that there were signs of movement where the girders rested on the piers. The first thing to find out was whether the girders were moving on the pier, or the pier moving under the girders; and observations extending over some time were necessary to settle this point. There was then no doubt that it was the pier that was moving and getting increasingly out of plumb. Fortunately, the next pier was an unusually massive one, and it was possible with a system of tie rods attached near the base of it to get hold of the faulty pier near the top, and entirely stop the movement. From the date of the first observations to the tightening up of the tie rods, there had been a movement of 1¼ inches.

Similarly, if one is called upon to deal with an abutment which is bulging and out of plumb, the first thing to find out is, to what the failure is due; is it, for instance, the result of (1) bad foundations? (2) of colliery workings (and old workings which nobody knows much about are sometimes very troublesome)? (3) of excessive pressure from swelling clay or defective drainage behind? or (4) of imperfect building and want of proper bond, or sufficient section in the wall itself? The treatment will entirely depend on the diagnosis. For instance, it would simply be waste of money to rebuild or reface if colliery workings were the cause of the trouble, unless indeed the settlement due to them had quite ceased.

In the design of new works the consideration of the likelihood of future alteration has a bearing on the materials to be used. If it is likely to come soon, one does not build with the some solidity adopted if the structure is to be one of real permanence. In designing bridge work, some of our predecessors in days gone by have added large margins to the calculated strengths of their structures, remembering the effect of corrosion and the tendency to increase the weights of locomotives, etc. We are now reaping the benefit of this liberal policy; for had things been calculated more closely, our maintenance expenditure would now be largely increased.

*Abstract of article in the "Journal" of the Junior Institution of Engineers, London, England, by A. Clifford Swales, Secretary.

HOW NEARLY DOES THE MODERN YELLOW PINE BLOCK PAVEMENT APPROACH TO THE IDEAL PAVEMENT AND WHAT IMPROVEMENTS CAN WE SUGGEST?

By H. L. Collier.

To intelligently discuss the matter let us get forth the cardinal points of an ideal pavement.

1st. It should be sanitary.

2nd. It should be durable.

3rd. It should be reasonable as to first cost.

4th. It should be easily, economically and effectually repaired.

5th. It should offer the least resistance to traffic.

6th. It should furnish good foothold to horses.

7th. It should be easily cleaned.

8th. It should be noiseless.

9th. It should possess elasticity, which would care for the horse.

10th. It should be dustless.

11th. It should have a smooth surface and wear uniformly.

12th. It should not be easily affected by climatic changes.

Finally. This being the automobile age, the ideal pavement should care for the automobile as well as for the horse.

As to the cardinal points, what claim can we make for the modern creosoted yellow pine block pavement?

First. We unhesitatingly say it is the most sanitary of all pavements, because it is made of only sound timber, thoroughly seasoned under a temperature of at least 240 degrees Fahr. in an air-tight cylinder; subject to a vacuum of from 22 to 26 inches of mercury, and under pressure of from 100 to 200 pounds per square inch; creosote oil, a distillate of pure coal tar, free from all adulterants whatsoever, is forced into the blocks until the pores are filled with the oil at a temperature of 240 degrees Fahr.

The heavy oil of creosote, a pure coal-tar distillate, free from adulterations, is not only a wood preserver, but also a most effectual disinfectant; a sure exterminator and preventative of germs, microbes, fungi and all other seeds of disease or decay.

The pores of the yellow pine blocks being thus filled under pressure will not absorb impurities, and creosote being ever present no germ can exist on the surface of the pavement.

Again, the blocks are manufactured to exact dimensions, rectangular in form, and are laid so closely and fitted around manholes, water keys, catch-basins, frogs, switches, etc., so snugly that the interstices are too small to admit any impurities.

Again, there is nothing about a wood block pavement to grind into dust, and no dust can appear thereon except that carried to the pavement; and as dust is not only a disease producer and also a disease distributor, and as all other pavements are at least ninety (90) per cent. dust producing materials, we say creosoted yellow pine block pavement is the most sanitary of all pavements.

Dr. Floyd W. McRea, of Atlanta, one of the most noted surgeons in the south, who served his city on the Board of Health, after a most careful examination of creosoted yellow pine block pavement, not only in this country but also in Europe, pronounced it the most sanitary and the best of pavements.

*Abstract of paper read before American Wood Preservers' Association.

Mr. H. Wheeler Bond, health commissioner of St. Louis, under date of March 2nd, 1911, wrote:

"In our opinion the creosoted yellow pine block pavement is not only sanitary in nature, but also considered the best street pavement in St. Louis."

Mr. James C. Travilla, street commissioner of St. Louis, under date of March 6th, 1911, wrote:

"The modern creosoted block is the most sanitary form of paving material on the market. The reason for this is evident, since the creosote used in treating the wood contains a large percentage of highly antiseptic ingredients, namely, Phenol, or carbolic acid, and Naphthalene. These ingredients are the lighter, more volatile portions of the preservative oil and continually come to the exposed surface of the blocks, the only portion of which collects germs, and thus keeps the street in a healthy, sanitary condition."

Second. We say also that creosoted yellow pine block pavement is the most durable of all pavements, even under heavy traffic. Tested side by side with granite on Hudson Street, New York, it was proven to be more durable. In U. S. Circular No. 141 we find in the above test, "one wood-block pavement outlasted three granite-block pavements under identically the same climatic and traffic conditions."

Williamsburg Bridge, New York, gives proof that wood block pavement is more durable than Medina sandstone.

On Michigan Boulevard, Chicago, asphalt blocks wore out in five years and wood blocks in same location under the same traffic were good at the end of nine years, certified to by Mr. Lynn White, engineer for South Park Commissioners, Chicago. On Holliday Street, Baltimore, after a test of six years, sheet asphalt, asphalt blocks and several different makes of vitrified brick pavements wore out and had to be removed, while wood blocks were perfectly sound and showed only a compression of ⅛ of an inch in the six years. At the present time, after twelve years' service, the wood blocks look as when new and no cost of repairs. All of these tests are described also in U. S. Circular No. 141.

On Tremont Street, Boston, in 1900, the test was made with asphalt by paving from centre to curb on one side with the very best quality of asphalt paving, and on the other side from centre to curb with the best quality of creosoted yellow pine blocks—all on six inches Portland cement concrete foundation. After nine years' service the asphalt was practically worn out, after having been many times repaired, while the wood blocks, according to the superintendent of streets, "seem in as good condition as when first laid; by actual measurement I find that they have been reduced ⅛ of an inch, but the surface is so regular the reduction in thickness of ⅛ inch must be from compression rather than wear. The wood blocks on Tremont Street have not received or required any repairs caused by either wear or decay in the nine years."

Messrs. Dow and Smith, experts of New York, in making their report to the Merchants' Association of Philadelphia looking to the paving of Market Street in said city, made this comment on Tremont Street pavement in Boston:

"To all appearances these blocks, although subjected to severe traffic for the past nine years, are practically as good as the day they were put down. There has been no maintenance cost whatever during the nine years the pavement has been in place."

In the same report Dow and Smith stated:

"Where laid along side of street car tracks the present wood blocks have outworn two sets of granite blocks similarly placed."

"Wood block paving down under heavy traffic from 10 to 12 years shows less than ¼ inch wear or compression, and none as yet having cost anything worth considering for repairs, while the life of all other pavements under heavy traffic is from 8 to 12 years—all requiring extensive repairs in three or four years. Therefore, we say creosoted yellow pine block pavement is the most durable of all pavements."

Third. While wood block pavement is slightly more expensive as to first cost than asphalt, bitulithic or brick, its wonderful durability and ease of repairs soon enable it to overcome any saving as to first cost by other pavements.

In New York, Chicago, Cincinnati. Philadelphia, St. Louis, Detroit, Minneapolis, Indianapolis, Atlanta and Boston wood block paving costs from 33⅓ to 50 per cent. more than asphalt, brick or bitulithic paving, yet in the business districts wood block paving is used almost to the exclusion of the other pavements named.

If, in ten years, the other pavements are worn out and have to be replaced with some other pavement, and under the same climatic and traffic conditions at the end of ten years, the creosoted yellow pine blocks show no wear and are as good as when first put down, would they not be cheaper and more desirable as an investment were the first cost double that of the other pavements?

Constant repair of pavements is a fearful nuisance to the business men of a city, and holes in a pavement are productive of a multitude of damage suits, the expenses of which should be charged to the faulty pavement.

Fourth. We say creosoted yellow pine block pavement is the easiest and most economical of all pavements to repair and is the only pavement that can be effectually repaired and made to look as well after repairs as before. And to repair wood block paving requires no expensive outlay—only a laborer, a hatchet and a few blocks necessary for any wood block repair.

The blocks are more easily trimmed to fit than are bricks. Square cuts have to be made for brick repairs, while wood blocks can easily be made to dovetail into the pavement and the pavement made as good as when new. Therefore, we say creosoted yellow pine block pavement is the easiest and most economically repaired of all pavements.

Fifth.—On account of its smooth surface, elastic and yet unyielding so far as impeding traffic, it offers the least resistance to traffic of all other pavements the year round. Asphalt and bitulithic paving, when of smooth and regular surface, in winter offer as little resistance to traffic as wood blocks, but in summer, when yielding, the tires sink in and considerable resistance is encountered.

Sixth. Wood block paving offers a sure footing to horses when dry or wet, as shown by the long, easy strides they take on said pavement. When slightly damp from a heavy dew or light frost or heavy fog, when the pavement is not clean, like asphalt and bitulithic pavements, is slightly slippery for a short while early in the morning under those climatic conditions, but no more slippery than other smooth pavements under the same conditions.

Seventh. Wood block pavement, made of perfectly rectangular blocks, can be laid with a smooth surface and the wear or compression is perfectly regular. The interstices soon iron-out (weld together), leaving no receptacle to hold dust or impurities and is easily swept and, there being nothing to produce dust, we say wood block pavement is the cleanest and easiest kept clean.

Eighth. Wood block pavement is known as the "silent pavement." Wood does not reflect sound, has elasticity and yields under the horse's tread, does not give forth the metallic sound common to all other pavements.

This noiselessness has transformed the down-town districts of all our large cities. With wood block paving even the busy marts of London, Paris, Berlin, New York and Chicago are free from noise and clatter, which before proved so nerve-wracking.

First, second and third stories of buildings which have been abandoned as offices and sales rooms, after improvements of the streets with wood blocks become the choice office locations.

Ninth. Wood is the only material out of which a road surface can be made which possesses elasticity at all times.

On a wood block pavement a horse would never become "stove up." Examine your city horses and see the effect of all other pavements on them. You will find that in three or four years on asphalt, bitulithic, brick or granite blocks paving horses become stiff—"stove-up."

The saving on horses and vehicles on wood block pavement would, in a few years, amount to a sum sufficient to pave with wood blocks all the down-town streets in our cities.

Tenth. We have already stated that there is nothing about a wood pavement that can grind into dust under the erosion of wheels or the impact of horses' hoofs; while all other pavements, except brick, are made of materials which are ninety (90) per cent. dust producing, and brick we know to be of 100 per cent. dust producing materials.

Eleventh. We say it can be laid with a smoother surface than any other pavement, and the experience the past twelve years has proven, under heavy traffic, the wear or compression is uniform and the surface continues smooth.

As example, for instance, Tenth Street, Minneapolis; Tremont Street, Boston; Washington Avenue, St. Louis—the latter is so very smooth the children make it, after ten years' service under a heavy traffic, a skating rink; and of Tremont Street the street commissioner of Boston, late in 1912, wrote: "After twelve years' wear it looks as smooth as when first laid." Of Tenth Street, Minneapolis, Mr. George S. Harper, of said city, wrote: "The pavement on Tenth Street has been down ten years and it is in as good condition now as when laid." So with all our creosoted yellow pine block pavements; not so with any other pavement—all, without exception, wear unevenly into ruts and chuck-holes.

Twelfth. It is the least of all pavements affected by heat and cold; neither does moisture seriously affect it. In Minneapolis more than 60 per cent. of all the pavements are creosoted wood block paving. Altogether there are 61 miles, and every yard doing nicely, and some down ten years. In Chicago, Detroit, Indianapolis, Toledo, Cincinnati, Boston, New York, Atlanta, Mobile, Pensacola, Beaumont, Dallas, Kansas City, Mo., also in all the large cities of Europe, the pavements have given entire satisfaction; geographical locations or climatic conditions seem in no wise to affect it. We have testimonials from street officials in every city sustaining this declaration.

Finally. As before stated, the elasticity and smoothness of the wood block pavement cares for the horse, fully doubling his years of usefulness over any other pavement, and in turn the horse does no harm to the wood block pavement.

The same reciprocity exists between the creosoted yellow pine block pavement and the automobile.

The smooth surface of the wood block pavement does not whet out the tires; neither is there found on a creosoted yellow pine block pavement chuck-holes or ruts to bend the axles or throw out of adjustment the delicate parts of an automobile; nor are there slivers to puncture the tires—in fact, on a creosoted yellow pine block pavement, properly constructed, an automobile should last almost forever.

In turn, under automobile traffic, a wood block pavement should last almost forever. The friction between the tires and the pavement in no wise hurts the surface of the wood blocks.

The automobile is a machine of destruction to all other pavements, and in turn all other pavements wear out rapidly the automobile—the grit cuts the tires like an emery wheel; the chuck-holes and ruts bend the axle and throw out of adjustment and shake to pieces all the delicate parts of the machine.

If the creosoted yellow pine block pavement possesses all these good qualities, and in a superlative degree, why is it not an ideal pavement?

What is it lacking?

How can it be improved?

What is said against it?

Our competitors say "It is slippery." "It bleeds." "It buckles." "It is unsanitary," and "While creosoted yellow pine block pavement can be made a better pavement than any other, it is so hard to make right, and so easy to make wrong, that is is seldom a city gets a first-class job." And in their extreme lamentations they say, "It requires an army of carpenters to keep it in order."

As to these criticisms, let us see how many are real and how many can be remedied:

First. The bleeding is exuding of the heavy oil injected in the blocks under pressure for two purposes—to prevent decay and to lessen the absorptive power of the wood. The bleeding is positive proof that the blocks have been impregnated with the oil which the engineer said should be, and the inspector declares has been injected. No one has charged that bleeding is injurious to the pavement, except as a temporary nuisance which almost always begins and ends in the first hot season, and which can be made unobjectionable by whipping a thin coating of sand over the pavement two or three times during that period, which labor and expense fall upon the contractor, who is "both ready and willing."

The bleeding is not without its benefit; it helps to form a mastic coating around the blocks, which aids in preventing absorption.

Up to 1908 creosoted wood block paving did not bleed; blocks laid prior to 1908 were treated with oil of light specific gravity and treatment—1.04 to 1.08 specific gravity, and about twelve pounds of oil to the cubic foot of timber.

Since 1908 a heavier oil and treatment have been largely used—from 1.10 to 1.14 specific gravity, and from 16 to 20 pounds to the cubic foot of timber.

Whether about 1908 there was any material change in the mechanical treatment of the blocks we do not know.

The question of seasoned or unseasoned timber for blocks before treatment is an unsettled question.

Since every pavement made of creosoted yellow pine blocks, impregnated with from 10 pounds to 22 pounds of creosoted oil, the distillation, or the product of pure coal tar, with specific gravity from 1.04 to 1.14 has proven successful, and "not one has cost any amount worth considering for repairs," declared by every city engineer during their long service under heavy traffic, some more than twelve years, many miles more than ten years—who can say whether light or heavy oil, light or heavy treatment, seasoned or unseasoned woods, is the best and will be the most durable. We who have spent years studying the pavement have our preferences on all these points, yet none of us can prove our ideas are best. Since the blocks show no perceptible wear, no decay for twelve years under heavy traffic, on what are we to base our arguments?

If I am asked my preference on these points, I would say:

Let the oil be a pure coal-tar distillate, unadulterated by any other material whatever, with specific gravity not lighter than 1.06 and not heavier than 1.08; on distillation not to show more than 5 per cent. up to 210 degrees C. and not less than 45 per cent. nor more than 60 per cent. up to 315 degrees C.

For light traffic, 18 pounds; for medium heavy traffic, 16 pounds; for heavy traffic, 14 pounds to the cubic foot of timber.

Second. As to buckling. This has been a most awfully over-ridden hobby-horse. There is nothing that can happen to any kind of pavement so inexpensive and so easy to repair.

Either lay the blocks with tight joints, both longitudinal and transverse, as has been the practice in New York, with ample longitudinal expansion joint at the curbs, filled with a bituminous filler so compounded as not to melt below 175 degrees Fahr. or become brittle above 15 degrees Fahr.

This method will prevent bleeding, buckling and slipperiness and will make waterproof the pavement.

Third. As to slipperiness. Creosoted yellow pine block pavement is, as are all other smooth pavements, slippery under certain climatic conditions. If the pavement is not clean (covered with a film of dust or soot), and the morning is mucky, heavy fog or heavy dew, or very light sprinkle of rain, or light frost or snow, the pavement will be, for two or three hours, slippery. This condition will probably exist for two or three hours one day in every week the year through, and not more than that in any section of the United States. All of which can be overcome by an occasional whipping of coarse sand on the surface.

If the engineer will make the crown of his wood block pavement as light as the grade of the street will admit, and if above 4½ per cent. grade, will separate the blocks transversely with a creosoted strip ⅝ x 1 inch and fill the joint above the strip (the strip to be set up on the concrete base), with the bituminous filler, already described, and pebbles, there will be very little, if any, slipperiness, not any more than on asphalt, bitulithic, concrete or brick with cement grout filler under the same conditions.

Fourth. All creosote plants buy their oil in large quantities, and as fully 90 per cent. of the treating of timber and paving blocks is done under expert supervision, selected by those who pay for the work, the danger of imposition is reduced to the minimum.

As to the quality of the wood, any novice can tell whether it conforms to the engineer's specifications.

As to the construction work of the pavement, it is practically the same as that of several other pavements—so, where can the deception be practiced?

Fifth. As to the sanitation of the pavement, proof sufficient has already been given.

Sixth. As to the extent of repairs, we have shown that no expensive plant or gang of trained laborers are necessary to be maintained for said purpose, but the only thing needed is a laborer, a hatchet and a few new blocks.

What Improvements Can We Suggest?—I think we are on the "right line,"—will only mention a few points which, after long experience, much study and many critical inspections, have impressed me as essentials.

First. Be careful in making the Portland cement base. Have the ingredients carefully selected and well mixed; proportion depth to traffic, and always finish the concrete base with a template and straight-edge, exactly parallel to the contour and grade of the finished pavement.

As to cushion for the blocks, I prefer the mortar bed—of one part cement and three parts screened sand, mixed dry, struck off with a template and dampened with a hand-sprinkler just in advance of the paver.

Lay the blocks close-jointed sidewise and with one-eighth inch joint between ends of the blocks, carefully spaced.

At the curbs provide an inch expansion joint for a thirty-foot street, between curbs, and 1½ inches for a 50-foot street.

Have no transverse expansion joints on the pavements.

Trim the blocks to fit neatly around manholes, catch-basins and all permanent fixtures; provide necessary expansion joints around same.

Let the blocks be brought to a firm bearing by means of a hand-rammer in the hands of an active, careful laborer, or quickly rolled with a light tandem roller, from three to five tons.

After the blocks have been spaced, inspected and low blocks brought up to grade, the surface should be swept broom clean and a bituminous filler, so compound as not to melt below 175 degrees Fahr. or become brittle above 15 degrees Fahr., heated until as thin as water, should be poured on the surface and worked back and forth with a squeegee until all cracks, interstices and expansion joints are three-quarters full, using sufficient force on the squeegee to leave only a thin coating on the surface of the blocks, into which, while hot, sprinkle a layer of pebbly sand.

Traffic should be excluded for at least four days, and longer if necessary, for the mortar bed to properly harden.

If a sand cushion is used, let it be only one-half inch in depth, made of screened sand not too fine.

This plan should be used universally on bridge floors.

What Should Not Be Done.—Blocks should not be loosely laid on a sand cushion, varying from ½ inch to 2 inches in depth and a sand filler used—remember, wet sand is as unyielding as granite. You could with equal propriety each day drive steel wedges between the blocks. As the blocks shrink the sand trickles down to fill the space made and keeps the blocks hugged in this narrowest limit. When the blocks are wet so also is the sand, and when the blocks want to expand to their natural sizes, the wet sand will not yield and a buckle of the block occurs.

If sand is to be used as a filler, lay the blocks close-jointed both longitudinally and transversely, and place a half-inch layer of coarse, pebbly sand on the surface.

Neither should a paving pitch filler be used unless specially made for the purpose, guaranteed not to melt below 175 degrees Fahr. or become brittle above 15 degrees Fahr.

Ordinarily paving pitch on a wood block pavement is a nuisance in hot weather, and below 50 degrees Fahr. it is absolutely unyielding. Wood blocks will want room for expansion below 30 degrees Fahr.

As to Treatment.—The period should not be too short—making haste is dangerous; gradual heat, not at any time to exceed 240 degrees Fahr., rapid vacuum up to 22 to 26 inches of mercury—slowly increasing pressure not to exceed 200 pounds.

Better retain 150 pounds pressure longer than hasten the work by applying 250 pounds pressure for a shorter time.

As to Timber.—Like the specific gravity of the oil, too much of a bugaboo is made of the amount of heart lumber to require. We have diligently searched for evidence to prove that sap in creosoted wood blocks wear more rapidly than heart, and not in one instance have we found such evidence.

The blocks, if laid level on a concrete foundation with close joints, the compression or wear has been perfectly regular, as much on the heart side as on the sap side.

The treatment seems to toughen the timber, making the heart and the sap of equal wearing surface in paving.

Therefore, we say there is no good accomplished in calling for 66 per cent. or 95 per cent. of heart. Such requirement adds considerably to the cost of the timber. Our mill men are anxious to sell heart lumber, but they greatly increase the price charged therefor.

Square-edged and sound Virginia southern yellow pine, free from all defects which would injuriously affect the timber for the uses intended, are all that is needed in an up-to-date, first-class timber specification for paving blocks.

With these precautionary suggestions as to timber classifications, treatment and construction observed, we will have in the creosoted yellow pine block pavement the ideal pavement.

COAST TO COAST.

Vancouver, B.C.—The contract for the building of the new police headquarters has been awarded to Mr. C. F. Perry, his tender being for $250,000.

Montreal, Que.—Canada has now 26,727 miles of railroad in operation, and 3,466 miles under construction. Gross earnings of Canadian railroads in 1912 increased 16.2 per cent.

Winnipeg, Man.—A report issued by the highways commissioner for the province of Manitoba shows that a sum of over $1,000,000 will be spent during 1913 on the highways of the province.

Montreal, Que.—The Montreal Trust Company estimate the total output of the Cedar Rapids plant, when completed, to be 100,000 horse-power This would mean an annual revenue of $3,500,000.

Montreal, Que.—Mr. George Janin, in his report to the Board of Control, estimated that it will cost three and a half million dollars to pave streets and sidewalks that are not paved now within a radius of two miles of the city hall.

Minneapolis, Minn.—The Minneapolis, St. Paul and Sault Ste. Marie Railroad will spend $25,000,000 in building 725 miles of new road, which will cross Montana and strike the Canadian Pacific road somewhere near the Montana-Idaho boundary line.

Hamilton, Ont.—The council has decided to contribute $25,000 towards the construction of the proposed concrete highway between Hamilton and Toronto, provided the Ontario government builds and maintains the new road starting where the asphalt pavement ends at the cemetery gate.

Guelph, Ont.—County Road Superintendent J. M. Young reported that the amount of money spent under the Highway Improvement Act for road and bridge construction from November 16th, 1911, to December 31st, 1912, was $33,597.38, of which $13,242.38 was for bridges and $20,355 for roads.

Sault Ste. Marie, Ont.—The H. E. Talbott Company of the Soo, have been awarded the contract for the construction of a 1,500 foot dam and the installation of a complete hydro-electric system at Grand Mere, Que. The contract involves a sum of over a million and a half and 1,000 men will be employed on the work.

Vancouver, B.C.—The province of British Columbia stands third among the provinces in the Dominion in amount of articles manufactured, producing $65,204,235 worth of goods; and fifth in the cities of the Dominion in the rate per cent. of increase of values of products with 695.16 per cent. for 1910.

Victoria, B.C.—Mr. W. Fleet Robertson, provincial mineralogist, has completed a preliminary review and estimate of the mineral production of the province of British Columbia for the year 1912, which sets the total value of the production for the past year at $32,606,000, or $9,106,928 in excess of the production for 1911.

Calgary, Alta.—Mayor Sinnot has submitted an estimate to the city council, providing for a $10,000,000 pipe line from Bow Island to Calgary and neighboring points, to be controlled by the municipalities and retailed at cost to manufacturers and other consumers. The Bow Island town council is preparing to operate municipal gas wells and furnish this natural fuel free to manufacturers locating here.

Hamilton, Ont.—Jas. Bain, electrical engineer, in his report shows that during the four months the two electrical pumps were in operation the cost per million was $6.35, while during the eight months coal was used the cost was $7.01. With the combined use of electrical power and coal, however, the average cost per million gallons was $5.23, the net saving by the use of steam to keep down the peak load being $1.11 for every million gallons.

Sarnia, Ont.—The Huron Lake Shore Railway, with a capital of one million, are seeking a charter to construct not only a railroad from Sarnia to Seaforth, but also a line of steamboats is contemplated by the company, which will mean the building of wharves, warehouses and other adjuncts of marine shipping. Telegraph and telephone service will also follow the line of the railroad. It is understood that hotels, pleasure resorts along the proposed route are possibly to be included in the plans of the company.

St. Thomas, Ont.—The City Council have awarded the contract for the construction of the new Just Wright shoe factory to Albert E. Ponsford, his tender for the complete work being $33,953. Other contracts in connection with the work are as follows: Sprinkling system, to cost $3,100, the General Fire Equipment Company of Toronto; vault doors, costing $56.25, Ford & Fetherston, of Hamilton; electric elevator, $520, will be supplied by the Otis-Fensom Company. The factory, complete, will cost $37,629.25.

Hamilton, Ont.—Articles incorporating the International Harvester Corporation, with an authorized capital of $70,000,000, was filed with the secretary of state at Trenton, N.J., the incorporators being connected with the International Harvester Company, a concern already chartered under the laws of New Jersey with an authorized capital of $140,000,000. The new corporation has been formed for the purpose of taking over the business and properties of the International Harvester Company in foreign countries, including the manufacturing plants in Canada, France, Sweden, Germany and Russia.

VANCOUVER BRANCH OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

At the annual meeting of the Vancouver branch of the Canadian Society of Civil Engineers, held on 20th January, 1913, the following officers were elected for the ensuing year: Chairman, G. E. G. Conway; vice-chairman, L. G. Robinson; secretary-treasurer, F. Pardoe Wilson; executive, C. E. Cartwright and W. A. Clement. Secretary's address, 422 Pacific Building, Vancouver.

ALBERTA ARCHITECTS' ASSOCIATION.

The annual convention of the Alberta Architects' Association was held January 23, 24 and 25, at the Edmonton Board of Trade Rooms, Edmonton, Alta. The following officers were elected for the coming year: President, R. W. Lines, Edmonton; hon. president, G. M. Lang, Calgary; 1st vice-president, Jas. Henderson, Edmonton; 2nd vice-president, J. J. O'Gara, Calgary; hon. secretary, W. D. Cromarty, Edmonton; hon. treasurer, G. H. McDonald, Edmonton. The following is the newly elected council: R. P. Blakey, Edmonton; L. Gibbs, Edmonton; Geo. Fordyce, Calgary; W. S. Mayor, Calgary, and R. P. Barnes, Edmonton.

MEETING OF THE SOCIETY OF CHEMICAL INDUSTRY.

A largely attended meeting of the Society of Chemical Industry was held last week in Montreal. Prof. R. F. Ruttan was in the chair. The lecturer of the evening was Mr. James O. Meadows, superintendent of the filtration plant of the Montreal Water and Power Company, who spoke on "Water Purification," with special reference to rapid sand filtration. In the course of his lecture he described various forms of chemical and mechanical filtration, and referred to the systems being installed for Montreal and suburbs. The lecture was followed by an interesting discussion.

PERSONAL.

SETON PORTER has been admitted as a member of the firm of Sanderson & Porter, consulting engineers, New York.

RICHARD S. BUCK has retired from the firm of Sanderson & Porter, of New York, and has become chief engineer of the Dominion Bridge Company, of Montreal.

GEORGE CRAIG, assistant city engineer of Omaha, Neb., has been appointed city engineer of Calgary at a salary of $5,000 per annum.

W. A. OSTROM, chief engineer of the power house, Saskatoon, Sask., has resigned his position and will become general erecting superintendent of the General Electric Company west of Winnipeg.

LEE MURRAY, M.C.E. (Melb.), M.Inst.C.E., M.I.E.E., M.I.Mech.E., who recently retired from the position of general manager of Messrs. Bruce Peebles & Company, Limited, engineers, Edinburgh, has started business on his own account in London as engineering representative (buying, inspecting, etc.) for firms and corporations in the colonies and abroad. Mr. Murray's address is 10 Norfolk Street, Strand, London, W.C.

PHELPS JOHNSON was born in Orange County, U.S. From 1872 to 1879, Mr. Johnson was engineer for the Hawkins Iron Works, at Springfield, Mass. In 1879 he became assistant engineer for the Wrought Iron Bridge Company, of Canton, Ohio. In 1882 he came to Toronto as engineer and manager of the Toronto Bridge Company, which afterwards became the Dominion Bridge Company. In 1888 he became chief engineer of the Dominion Bridge Company, at Lachine, P.Q., which position he retained until 1892. In 1892 Mr. Johnson was appointed general manager of the Dominion Bridge Company, which position he holds to-day. Mr. Phelps Johnson is also president of the St. Lawrence Bridge Company, which company was formed to construct the steel superstructure of the new Quebec bridge. Mr. Johnson is a member of the St. James Club, the Engineers' Club and the Royal St. Lawrence Yacht Club of Montreal. Last year at the annual meeting of the Canadian Society of Civil Engineers he was elected a member of the council.

Phelps Johnson, the New President of the Canadian Society of Civil Engineers.

RAY R. KNIGHT has received the appointment of city engineer of Fort William. Mr. Knight, who is an associate member of the Society of Civil Engineers and associate of the Institution of Municipal and County Engineers, is at present chief designing engineer in the sewer department of the city engineer's office, Toronto. During the two years he has held this position he has been responsible for the design and planning of sewerage schemes and storm sewers to the value of nearly $4,000,000. In addition to this he was called upon to report and give estimates for the disposal of the house refuse of Toronto involving an expenditure of $900,000. Before coming to Canada, a little more than two years ago, Mr. Knight was deputy town engineer of Bromley, England, and for five years previously held a similar appointment at Wood Green, London, England. Special street railway and sewerage work occupied his time before this at Folkestone, England. He was articled to the town engineer, Carnarvon, North Wales. For nearly sixteen years Mr. Knight has been engaged in municipal engineering in every phase, including many large sewerage, street railway, roadway and waterworks undertakings.

FRANCIS C. GAMBLE, the new vice-president of the Canadian Society of Civil Engineers, is the second son of the late Clark Gamble, K.C. He was born in Toronto, on October 23rd, 1848. His early education was received in Upper Canada College and by private tuition. He began his engineering career on the Intercolonial Railway in 1869. In 1872 he was assistant engineer on the Canadian Air Line (Great Western Railway), subsequently he became resident engineer for the contractors on the P.E. Railway. He was assistant engineer for the Intercolonial Railway, the Q.M. & O. Railway, and the Canadian Pacific, at Rat Portage, during construction. In 1880 Mr. Gamble was sent to British Columbia as assistant engineer on Government work above Yale, B.C. He was afterwards transferred to the Department of Public Works of Canada in British Columbia. In 1887 he was appointed resident engineer in the province which position he resigned in 1897 to become public works engineer and inspector of dykes for the province of British Columbia. In 1911 he became chief engineer and inspecting engineer of Railways for British Columbia. Mr. Gamble was elected a member of the society in 1887. He is also a member of the Institute of Civil Engineers, of London, Eng., and of the American Society of Civil Engineers.

Mr. Francis C. Gamble, Vice-President of the Canadian Society of Civil Engineers.

S. BRUCE McCONNELL, Assoc. M. Can. Soc. C.E., formerly assistant division engineer of the Canadian Pacific Railway, at Montreal, Que., has been promoted to be assistant engineer. His headquarters will remain at Montreal. Mr. McConnell entered the railway service in 1898 as a transitman on the location of the Midland Railway of Nova Scotia.

Later he was transitman and resident engineer on construction of the Great Northern Railway of Canada, and resident engineer of a railway in Cuba. He joined the engineering staff of the Canadian Pacific in 1902, as assistant engineer in charge of yard construction at North Bay, Ont.

MAJOR W. W. CROSBY, M.Am.Soc.C.E., chief engineer to the Maryland Geological Survey, and consulting engineer, Baltimore, Md., on January 31st delivered an illustrated lecture on "Engineering Duties and Responsibilities," before the graduate students in Highway Engineering at Columbia University.

OBITUARY.

JULIAN THORNLEY, M. Am. Soc. C.E., died in the Masonic Hall Building, New York City, December 28. He was 44 years old, was formerly an engineer with the New York State Water Supply Commission, and was at one time resident engineer on the construction of the plant of the Electrical Development Company at Niagara Falls, Ont.

COMING MEETINGS.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. Fourth Regular Meeting. Toronto Section, will be held at Engineers' Club, 96 King Street, West, 8 15 p m , Friday, February, 7th, 1913. Secretary, H. T. Case, 611 Continental Life Building, Toronto

UNIVERSITY OF TORONTO ENGINEERING SOCIETY.--Meeting on Wednesday afternoon, Feb. 12th. Illustrated lecture by Mr. David Molitor of Engineering Staff of the Panama Canal. H. Irwin, Secretary.

ILLINOIS WATER SUPPLY ASSOCIATION.—The Fifth Annual Meeting of the Association will be held at the University of Illinois, Campaign-Urbana, Ill., March 11th and 12th, 1913. Secretary, Edward Bartow.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.—Annual Meeting will be held March. 3, 4 and 5, 1913, in the Green Room, Congress Hotel and Annex, Chicago, Ill. Secretary, Will P. Blair.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod

KINGSTON BRANCH—Chairman, A K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa: Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos: meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James: Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway: Secretary-Treasurer, F. Pardn Wilson, Address: 422 Pacific Building, Vancouver B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary R. W. MacIntyre: Address P.O. Box 1290

WINNIPEG BRANCH—Chairman, J. A. Hesketh: Secretary, E. E. Brydone-Jack: Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O Box 7, St Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—P ident, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O , Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W H Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

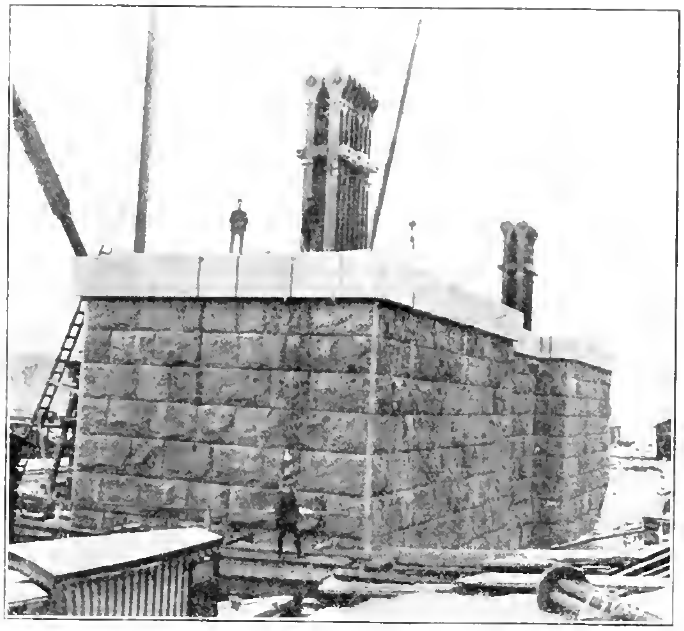
An Engineering Weekly

PROGRESS IN CONNECTION WITH THE CONSTRUCTION OF THE QUEBEC BRIDGE.

Very satisfactory progress has been made in connection with the construction of the huge Quebec bridge, situated some seven miles above the city of Quebec.

The contract for the substructure was let in January, 1910, and the contract for the superstructure in April, 1911. The work on both contracts has gone ahead as rapidly as possible since these dates, and at the present time there are material evidences to prove that before very long the River St. Lawrence will be successfully spanned by the largest bridge in the world.

Owing to the increase in weight and width of the superstructure, the piers of the old bridge had to be removed and new ones constructed in their place. All the more difficult work in connection with the substructure is now practically completed. The caissons for the north and south main piers have been sunk to the required depth, that for the nortn pier about 50 feet and that of the south about 85 feet below the bed of the river. All the rest of the work in connection with the substructure is above high-water mark or protected from the water, and presents no serious problems. The masonry involved in this contract includes alterations to the existing abutments and the entirely new construction of one intermediate pier, two anchor piers, and two main piers. The total yardage in these various pieces of masonry amounts approximately to 105,000 cubic yards. The timber used in the caissons is mostly 12-inch by 12-inch long leaf southern pine, and some 18,000,000 feet B.M. were used in the construction. The piers on the north side of the river are well advanced, and will be ready to accommodate the steelwork early in the coming season.



View Showing North Anchor Pier with Eyebars Extending Above.

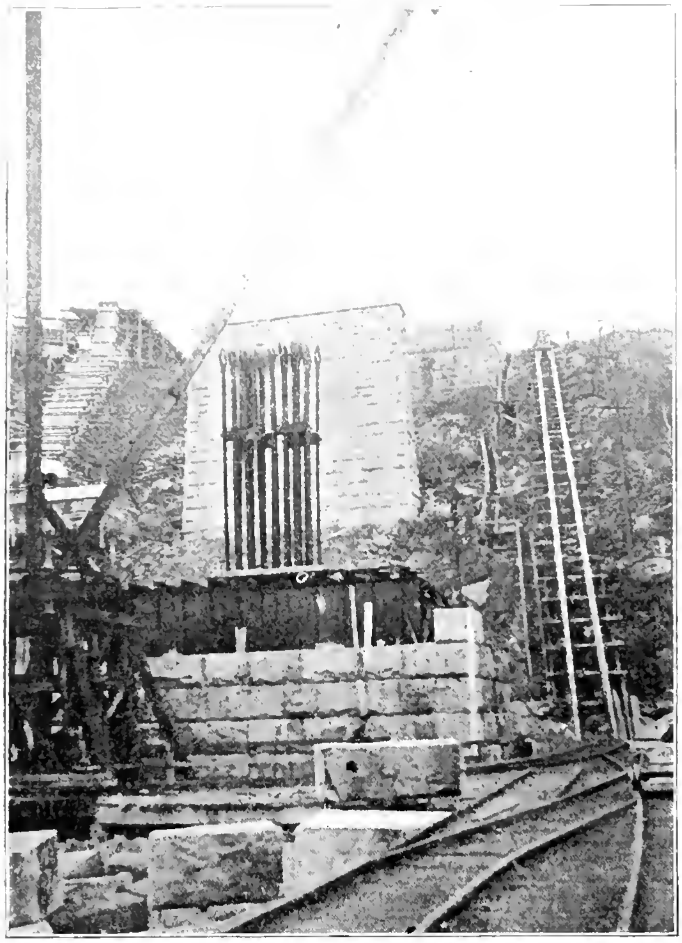
This pier will be extended 100 ft. higher than is shown here. Some idea of the enormous size of the stones can be gained by comparing with men in the picture. Dec. 2nd, 1912.

Since the awarding of the contract for the superstructure, the contractors, the St. Lawrance Bridge Company, of Montreal, have had a staff of between thirty and forty men engaged in their offices working on the detailed plans of the design. The design, details and problems in connection with this bridge are to a large extent without precedent, and as a result much time has been spent in investigation and studies that would not have been necessary with a smaller structure.

Plan after plan has been made, studied and revised, no detail of construction or calculation being too insignificant to court the minutest investigation. The contractors work in conjunction with the designers and calculators of the board of engineers, and no detail was passed unless thoroughly approved by both. Entirely independent sets of calculations were made by the board of engineers, each calculation being checked and re-checked independently so that there could be no possibility of error creeping in. Therefore, each simple calculation was subjected to two independent investigations by the contractors and two independent investigations by the board before it was finally approved. The suspended span was first designed and shop drawings completed from which the actual dead loads were computed before starting on the cantilever arm, which is in turn being completed before the drawings of the anchor arm are made. It can therefore be seen that there can be no chance of over-run in dead weight in the completed structure, as was the case in the old bridge.

The enormous proportions of this bridge cannot be properly appreciated until actually viewed in place. Some idea, however, may be gained from the following facts:—The completed bridge will probably exceed 50,000 tons of steel, equivalent to 1,700 carloads of 30 tons each, or over 500 train loads of 30 cars each. While this is an enormous quantity of steel to go into any one structure, yet there would be no difficulty in handling it were it manufactured in the ordinary commercial sizes used in bridges and structures to which we are accustomed. The great difficulty of the mechanical side of this enterprise arises from the fact that nearly all the members of the bridge are of such enormous proportions that the ordinary shops or equipment are entirely inadequate to manufacture or handle them. Shops with columns and girders of unusual strength are required to carry the heavy cranes which handle the enormous members. Almost every piece of machinery used must be of the largest capacity, and in the majority of cases are specially designed for this job.

The main posts of this bridge are about 10 feet by 10 feet in outside area and approximately 320 feet high, or equal to the height of a thirty-story building. The shoes on the main pier upon which each of these posts rests are 21 feet by 26 feet square and 15 feet high. Many a family lives in a house



View Showing Lower Anchorage, Girders and Eyebars in Place.

(Also completed intermediate pier and abutment in the background).

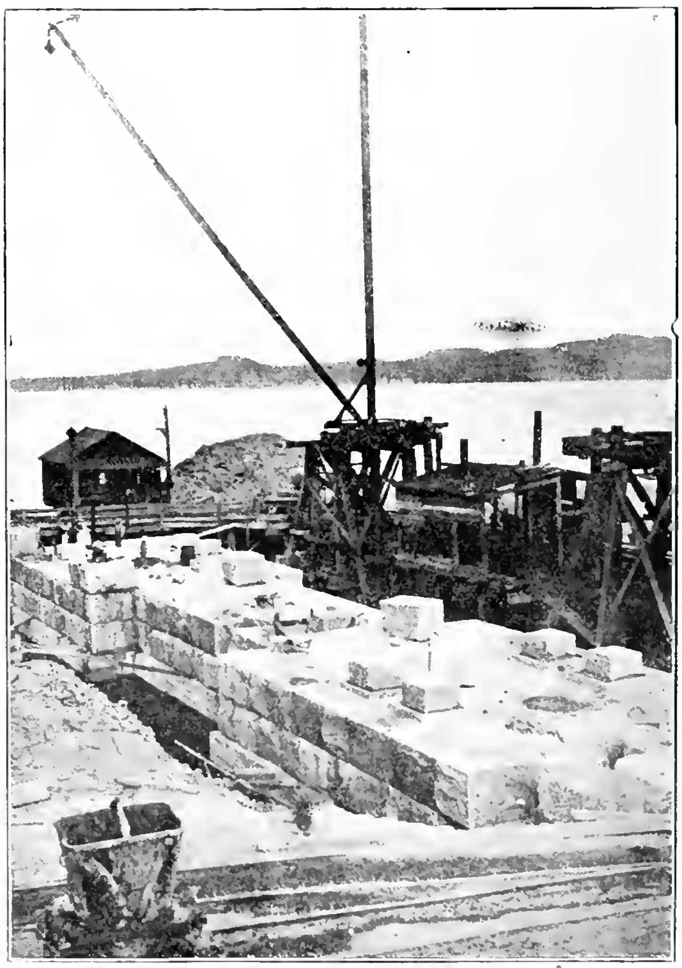
considerably smaller. The main bottom chord near the pier is about 10 feet wide and 8 feet high. If it were not for the interior webs and diaphragms six men could walk abreast inside this chord without crowding or fear of hitting their heads. This chord will weigh about 8,500 lbs. per lineal foot and is erected in sections weighing from 75 to 100 tons each. The main floorbeams are approximately 90 feet long and 10 feet deep, and weigh between forty and fifty tons. In most cases they are connected to the truss by pins in order to do away with the secondry stresses in the posts. The top chords of the cantilever and anchor arms are composed of two banks of eyebars of half panel lengths, and are supported by light Warren trusses between main panel points.

The floor system is designed to carry two railway tracks and two sidewalks for pedestrians. No allowance is made for highway traffic.

Elaborate preparations are being made by the contractors for the erection of this steel work. Erection will be carried on on both sides of the river simultaneously, which means a duplicate erection plant throughout. While this entails somewhat more expense for the contractors it will be justifiable by the saving of time. The anchor arms will be erected on heavy steel falsework which is so designed that the trusses will be carried on falsework independent from that which carries the traveler. The main traveler will be an enormous structure about 200 feet high and weighing, inclusive of hoisting machinery and tackle, about 900 tons. The traveler is constructed with an overhang from which heavy blocks are suspended and operated by means of electric hoists. Each hoist is capable of lifting 50 tons simultaneously, 60 feet beyond the point of support. The traveler is also equipped with cross gantrys and electric cranes and enormous booms which can handle material in practically every position. The blocks for the dozen or more hoists used in this traveler have all to be specially designed and constructed, many of them being over 5 feet in height and weighing over 5,000 lbs. each.

Probably one of the most interesting features of the erection will be the floating in of the 640-foot centre span. By means of this scheme of erection the difficulty of joining up at the centre is overcome and one year saved in the erection of the bridge.

While the floating in of a bridge span is a common enough occurrence to bridge erectors, yet, taking into consideration the length, weight and height of this span, and also the fact that there is a seven or eight-mile current and a 20-foot tide at this point, it can be seen that this part of the work is also without precedent. It is proposed to erect this span on steel falsework or staging on the shore or in shallow water at some point near the bridge site. This falsework is founded on concrete piers so spaced as to allow pontoons to



Starting Construction of the North Anchor Pier.

(View shows granite bed rock in place upon which steel anchorage is to be placed. Sept. 11, 1912.)

float in between them and under the falsework. When the span is completely erected and ready to be floated, the pontoons are placed in position under the falsework when the tide is low. As the tide rises the pontoons lift the bridge off the concrete piers. After the span has been towed to its

proper position under the bridge it has yet to be lifted over 130 feet in the air and connected to the ends of the cantilever arms. This is done by means of hangers with slotted holes which can be quickly attached to the four corners by means of pins. After this has been done at highest tide the pontoons are floated from under and the span is lifted in place by jacks at each corner of the cantilever arms.

View Showing North Main Pier.
(Completed up to high water mark and the caisson removed. Nov. 8th, 1912)

Entirely new shops have been constructed by the St. Lawrence Bridge Company, of Rockfield, near Lachine, and manufacturing has just been started. This shop is completely equipped with the latest and most powerful electrically driven machine tools, and will have a capacity of about 2,000 tons a month.

The supervision of the entire work is under the direction of the board of engineers appointed by the government. Mr. C. N. Monsarrat is chairman and chief engineer, with whom are associated Mr. C. C. Schneider, of Philadelphia and Mr R. Modjeski, of Chicago.

THE PRINCIPLES OF SCIENTIFIC MANAGEMENT.

On the occasion of his visit to Toronto to address the Canadian Club, Frederick W. Taylor, M.E., gave an address on "The Principles of Scientific Management" to the Engineering Society of the University of Toronto, on January 21st, 1913.

In his opening remarks Dr. Taylor presented his subject as referring principally to workers of co-ordinated industry, in distinction to isolated workmen, it being applicable only to the former.

Nineteen of every twenty workmen believe that it is to their best interest to turn out as little rather than as much work as possible. It is the most serious fallacy that possesses our working class, and is attributable to two causes, for neither of which are the workmen themselves to blame.

First, if it be suggested to a group of workmen that they double their output, they reply that the procedure would throw one-half of their fellow-workers out of employment. To them it appears self-evident, and others, among whom are many of our philanthropists, uphold the belief, heralding over-production as one of the greatest social evils conducive to national idleness. It is immensely true in every trade, so its followers believe, that in going slow, their interests are advanced. Any device, therefore, tending to increased output is rebelled against by this deeply rooted nature.

No more fallacious than such belief exists, and it is borne out by history everywhere, with but one exception, that the introduction of such a device or system, into any trade, instead of forcing men out of work, has provided more work for men of that trade The exception is in farming. Improved processes in the United States have reduced the providers of food supplies from eighty per cent. in years past to thirty-five per cent. at the present time, because the human capacity for food does not increase from generation to generation. This is the only instance where such a condition obtains.

As an illustration of the effect in other forms of labor, Dr. Taylor referred to the cotton industry, its history being comparatively older and its evolution more spectacular. The power loom was invented early in the last quarter of the eighteenth century, but the year 1840 witnessed the climax of its introduction, after a struggle many years in duration, to gain entrance into the manufacturies. In Manchester, Eng., the workmen felt that these looms would throw 3,500 of their 5,000 men out of work, and they strongly resented such outside intervention between them and their daily bread. Conditions were grave, as it was most difficult in those days to change one's trade, or even to move from one works to another. No alternative means of livelihood presented itself. The result was clear and concise. They forced the establishments, destroyed the looms, and maltreated the operators. Their rioting, however, did not affect the entrance of the loom into the industry.

Be the means what it may, bitter opposition, adverse legislation, public opinion, trade unions—all forces are powerless and futile in defeating the introduction of labor-saving development, and the effect is frequently that of accelerating its use.

The speaker stated that there is great opposition from labor leaders to scientific management, but since that opposition has become open and strong, scientific management has gone ahead more rapidly.

The result in the case of the cotton industry in the three-quarter century that has elapsed has been that the workmen have been proven wrong in their convictions. Has the increase of output thrown laborers out of work? In 1840 there were 5,000 workers. At the present time there are about 265,000 employed at the same work in Manchester. For every yard of cloth in 1840 there are now five hundred yards manufactured, though the population of England has not more than doubled within that time.

"There is a broad meaning back of it all. Wealth need only be brought into the world, for the world to use it. Although there are undeniable cases of over-production, they are abnormities, due to a general cause—the world undertaking a greater number of new enterprises than available capital warrants. It is a disease to which the public is susceptible, and the panics of 1873 and 1893 are unforgotten. On the other hand, production is necessary to wealth, which is derived from two sources, viz., out of the ground and by manufacture at the hands of man. The relation of wealth to production should be recognized, particularly by the poorer classes; their impression is erroneous that by far the major

part of the bounties of this world are consumed by the wealthy classes. The reverse is the truth.

"The best index of progress in the world is the increase in output per individual, it being a measure of the increase of prosperity of the individual. The 'good old times' slogan indicates the user to be ignorant of conditions, as increase in output per man has provided such a variety of good things of life that the workmen of to-day live as the kings of yesterday. Luxuries of history are considered necessities now."

Reverting to the previously discussed condition in the farming industry, apart from those who provide the food supplies in the United States, sixty-five per cent. of the population may now engage in other industries as against the twenty per cent. years ago. This indicates increase in output per individual, which is the object of scientific management.

The second belief the workman entertains as a reason for going slow, Dr. Taylor emphasizes as being again in no way attributable to the man himself. It is illustrated by the case of a workman being paid $2.50 per day and making 10 pieces a day, entering then upon the piece-work system. The foreman pays him twenty-five cents per piece for the ten pieces which he turns out. Gradually the laborer increases his output, probably reaching twenty pieces per day, thereby doubling the contents of his pay envelope. Both laborer and foreman are well satisfied with the result.

But at the annual meeting of the board of directors, the pay-roll may properly be called for and closely examined. The foreman must explain his action in paying $5.00 per day instead of $2.50 per day. A storm of protest ensues, savoring of competitors' prices and pay-rolls, and resulting in measures to prevent the supposed ruin of the firm's labor market. The foreman is obliged to reduce the workman's salary to perhaps $2.75 per day.

"There are a great many bitter things said against the workingman, concerning his selfishness, his tyranny, etc.; some of them are true, but there is just one thing that the working man of our country is not—he is not a fool. It is only necessary to give him one lesson, or at the most two, and he becomes a 'soldier' for life. He studies just how much the management will permit him to earn, and that is the amount of his output."

The fallacy of going slow is of such vital importance that the evil of it cannot be pointed out too strongly. There is not the slightest doubt that this is the greatest evil of the age in England She is suffering from under-production, not over-production, and no voice is raised in protest. England preceded this continent by a generation in the adoption of the policy of "soldiering," and the result has been detrimental in the reputation of the working man hailing from her shores, although he is, especially the steel worker, the most skilled workman in the world. The speaker cited cases where the laborer from across the seas absolutely refused to increase his output, curtailing it at every turn, thus necessitating drastic measures against his employment. The same thing is going on in England to-day and is the reason for unemployment and poverty. The policy of curtailing output strikes at the very root of the trouble.

"The first step of scientific management was to endeavor to prevent this diminishing output, and each succeeding step has been an earnest endeavor to remedy other existing evils in previous forms of management. Scientific management is no new or untried theory, and is no food for profound suspicion. It is a gradual evolution tested and proven step by step. It is the fruit of many men's ideas. Some years ago over fifty thousand men were working under its principles while the number has probably doubled since that computation was made.

"As in the case of all labor-saving devices, the ultimate result is that the general public gets the entire profit. The end of it all is that the whole world is going to profit from it. At first the companies that have introduced it are reaping large profits, many of them more than doubling their output. They are the pioneers, and as such are entitled to the gains."

A workman under scientific management immediately increases his wages from 33 to 100 per cent. This increase is not the greatest good to the working people, however, but the change of mental attitude toward work on the one hand and employers on the other is a more important part of their lives. They have changed from war to peace. There is now co-operation for the same object. The old suspicious watchfulness is supplanted by confidence, peace, conscientious work, and, on the whole, a feeling of satisfaction and pleasure that the employers are profiting as well as themselves. Scientific management has been introduced in almost every department of industry, and in the thirty years in which it has been thriving there has not been a strike in a place where it has been in force, although scores of strikes have occurred in other and similar works.

"It is not any efficiency device for increasing output; it is not a bonus system; it is not a cost system; it is not motion study, or time study; it is not unloading a lot of blanks at the goods entrance and saying, 'There is your system, go ahead and use it.' Most people think of it as one of these things. Scientific management cannot and does not exist until there has been a complete mental revolution on the part of the workmen and the employer, and until this great and complete mental revolution has taken place, scientific management does not exist."

Part of the cost of manufacturing is the cost of material. Another part is the cost of production of the article, and a third is the overhead expense. The difference between the sum of these three and the selling price is the surplus. All labor troubles are due to the division of this surplus. The workmen desire as much as they can get in the form of wages, etc., and the owners as much as they can get in the form of dividends. Under scientific management they have ceased combat over the division of this surplus. The result has been a surplus so large that both contenders get more than they ever received before. The workmen get at least 33 per cent. more wages, and the company gets larger profits. This is one result of the mental revolution.

Dr. Taylor pointed out forcibly the delusion almost universal among workmen that the division of the surplus in the past has been entirely wrong; that the working men are not getting their proper share of the general profits of capital and labor. Although in some cases it is true, their feelings have been rashly augmented by the labor leaders, newspapers and the public. In an article on "Division of Capital," in the Atlantic Monthly of June last, Norman Faig showed their conviction to be wrong. All that the working man can ask for is that the profits that accrue to capitalists should come to the people of the United States. They themselves could not demand all this profit. If it should be divided in the manner suggested there would be thirteen cents per day per man as dividend. It shows conclusively that the hope of the workman does not lie in the division of capital. It lies rather in an increase of output.

The speaker outlined the older type of management where, for example, 500 to 1,000 men in perhaps twenty different trades, have acquired their knowledge, not by books, but by observation and by traditional word of mouth. This is just the condition that obtained in the middle ages, and still largely obtains. Yet, in spite of lack of progress his trade is the workman's greatest asset. To achieve the best results one realizes that he must get the initiative of his workmen, but one's realization of "soldiering" forces him to the conclusion that to render this initiative the workman must receive a larger remuneration than his competitors.

The employer who has the pluck to do this, and to continue doing it, will find that his men will respond to such good treatment. This is the highest type of management under the old system, yet it cannot compete with scientific management, for under the latter there is no spontaneity on the part of the workman, but continuous effort. This, because of the new and unheardof burdens which the management assume.

The first of these principles is the gathering-in of the great mass of traditional knowledge held by the workmen; recording it, and reducing it to laws, rules and mathematical formulas. These deductions become of immense assistance in increasing the output. Rule-of-thumb knowledge is replaced by science.

Secondly, it becomes the management's duty to study carefully every man in the plant, his capacities, possibilities and limitations; and to train each to the highest class of work for which he is shown to be fitted—progressive selection and progressive study.

Thirdly, the science and the scientifically trained man are brought together. This is difficult. It can be accomplished only by binding the workman to work by science. This, however, does not cause appreciable trouble. Nine-tenths of the trouble experienced comes from forcing the management and owners to assume their burdens.

And, fourthly, a great mass of work formerly done by the workmen is now partly taken over by the management, until the whole is more equally divided. On the management's side there is generally one man for every three workmen.

These principles are deduced from years of study and work under scientific management. The system is no longer something which might be found beneficial if tried—it has been well tried—and pays.

To illustrate the application of the principles of scientific management, Dr. Taylor chose the operation of shovelling. A careful study and series of observations in a plant where four hundred to six hundred shovellers were employed resulted in a reduction in the cost of handling iron ore from eight cents per ton to less than four cents, after paying the workmen employed 60 per cent. higher wages, establishing a labor office, employing teachers to instruct the men how to scientifically handle a shovel, and timekeepers, etc., to record performances.

Investigation showed that the loads upon shovels under old methods varied from three and a half to thirty-eight pounds. Placed on a scientific basis, a load of about twenty-one pounds to the shovel, proper motions, simple and untiring, the work was now being done by 140 men. Furthermore, investigation into their private affairs showed the workmen to be living better lives, in every way, than before.

Illustrations were also given in the operation of machinery. The speaker claimed that not one in fifty of the machines in the factories of America are speeded accurately. The majority of them are 200 per cent. to 400 per cent. out, and from two and a half to nine times as much work could be done by them if they were properly adjusted. In the work of the high-class mechanic science is so great a factor that he cannot gain the proper knowledge of himself.

Dr. Taylor instanced, in closing, a case in machine manipulation where mathematicians were confronted with a problem involving twelve unknowns, and struggled with it for eighteen years. Now the problem is solved in twenty seconds on a slide rule taking care of the twelve variables.

"If you are willing to pay the price in time and hard work, things that have through the ages been termed impossibilities, can eventually be solved and put to use for the good of man."

MANITOBA'S MINERALS.

By Dr. R. C. Wallace.*

It cannot be said that a great deal of attention has been paid to the possibilities of Manitoba as a mineral producer. This is as might be expected in a province where agriculture has been and is of paramount importance. And yet the soil is not the only natural asset of any country; and a systematic investigation of the mineral resources must always play a prominent part in contributing to the development of the whole.

If we associate with the name of minerals such ores as are mined for gold or silver or copper, then it is indeed the case that minerals and good agricultural soil are not, as a rule, found together in nature. But under mineral resources must also be included materials such as clays, shales, sands and gravels, limestones, marls and coals, all of which are frequently found in districts which support a thriving agricultural population, and all of which call for development in the agricultural areas of our own province. One need only instance the case of our neighbor across the international boundary line, where a strong State Geological Survey and equally strong School of Mines, both integral parts of the University of North Dakota, are doing magnificent combined work in directing the development of the clays, cements, and coals of that state along the most rational and economical lines. A study of the features of industrial progress in a state pre-eminently agricultural, which are to be directly attributed to the researches and guidance of these organizations, would well repay the people of Manitoba.

But at a time when the province is on the eve of entering into a larger heritage, it is natural that attention should be directed rather to what we are likely to obtain than to what we already possess. Although certain areas in the vast Archaean territory of the new Manitoba have a coating of clay sufficient to provide an agricultural soil, the possibilities of revenue lie mainly in the mineral resources, the timber, the fisheries and the water power which the new territory will provide. And it is here that the onus of the work will fall. Up to the present time it has been found possible to carry out organized geological survey work only along some of the principal waterways, and private prospecting has been desultory in the extreme. In order to realize the extent of our possibilities, and the importance of systematic work in this field, it need only be pointed out that in a district—comparatively speaking at our own doors—a discovery of gold was made over two years ago which has led to the influx of a large number of prospectors into that particular area; and this in a belt which had not previously been geologically examined or even topographically mapped.

In the great Archaean Shield discoveries of ore deposits have been confined to the belts popularly known as Huronian, and consisting usually of Keewatin, Huronian, and even younger deposits, which may be generally characterized as dark or dark-green schists, conglomerates and slates, in contradistinction to the lighter color of the surrounding Laurentian granites and gneisses. Of these dark schists there lie within the enlarged boundaries of the province several areas, no one of which has as yet been subjected to detailed investigation. Future exploration may discover still more such areas, and it is certain that the boundaries of some of those already located, as for instance the "Huronian" band in the basin of the Hole River, will be considerably extended in the future mapping of the areas concerned. Two of these "Huronian" belts—one of them rather extensive in area—will be rendered directly accessible by the Hudson Bay line. A

* Professor of Geology and Mineralogy, University of Manitoba, Winnipeg.

third is connected by water route with Cumberland House and the Saskatchewan. Our knowledge of the existence of a fourth is primarily due to the fact that it lies along the well-used canoe route between Norway House and York Factory. Other areas lie near God's and Island Lakes; and the Black Island and Hole River belt extends eastwards beyond the limits of the province.

What these formations will produce is as yet largely a matter of conjecture. One district—that of Star Lake—near the eastern boundary of the province, and forming the western extension of the Lake of the Woods area, has now reached the producing stage, and gold mining in the province is happily an assured fact. Another, the Hole River and Rice Lake area, has been the scene of exceptional activity during the past year, and capital is now interested in developing this district, in which gold has been found over a wide area, and which, if present indications may be taken as a guide, will be producing gold within the next two years. Gold has been found in more than one of the other areas referred to, iron in several, specimens of copper ore are by no means uncommon, and discoveries such as have been made at Sudbury and Cobalt, names of worldwide importance, are by no means beyond the range of possibility. And in this connection it may be well to remember that although Cobalt is only a few miles distant from one of the earliest routes of travel in the country, its wealth lay hidden till some ten years ago; and it was due to a cutting for the Canadian Pacific Railway that the world's attention was first directed to Sudbury.

But the glamor of the Northland ought not to blind us to the necessity of utilizing the resources more easily available within the limits of the province. If Portland cement were manufactured from raw materials mined in Manitoba, a very considerable saving in freight rates might be effected. Limestones sufficiently pure for this purpose outcrop at various points on Lake Manitoba, and the necessary clay or shale is available conveniently near at hand. The calcareous Niobrara shales provide a suitable material for a natural cement, and future investigations in this direction may result in considerable increased activity. Valuable gypsum deposits are mined in the vicinity of Lake St. Martin, and in the country between Lake Manitoba and Lake Winnipeg other beds may yet be found. Borings have shown the existence of gypsum over wide areas at varying depths from the surface. A pure friable sandstone at the base of the sedimentary strata of the province will provide a good material for a future glass industry. A good phosphatic shale which is found in the western part of the province will come into requisition as a fertilizer when the soil begins to show signs of exhaustion. Our limestones are already a valuable asset, not only from the point of view of building-stone, but as lime and rubble producers. Extensive northern areas of limestone are awaiting development, and for the furtherance of the "Good Roads" movement not only the limestones, but also the available sand and gravel ridges will be utilized. Because of our great clay resources the brick and tile industry will occupy a very prominent position for many years to come; and the Geological Survey is at present investigating the possibility of utilizing the stiff till underlying the upper clays. With regard to fuel, the value of peat is being more and more emphasized in Canada and elsewhere; and Manitoba has her fair share of this commodity. Of lignites, Turtle Mountain contains on a rough estimate 160 million tons; and the formations in which lie the Lethbridge lignites extends into Western Manitoba, and deep borings may yet repay the expense they entail.

In reviewing the mining situation of Canada for 1911, the Canadian Mining Journal is compelled ot state that this province pays as yet practically no attention to exploiting her mineral resources. When, however, the greater Manitoba of the future acquires the control of her natural resources, the authorities will undoubtedly see their way to initiate a vigorous policy of development of the minerals we will then possess.

Statement of Production, 1910-11.—The following figures are given as summarizing the present situation, in so far as can be done with the latest available figures. They will also serve to contrast the present with possibilities for the future, when serious attention is given to developing our minerals.

Total production for 1911	$1,684,677
Total production for Saskatchewan	618,379
Total production for Alberta	6,404,110

Detailed Statement for 1910.

Gypsum	$195,000
Clay products and sandlime brick	735,232
Granite	3,345
Cement	21,995
Lime	100,808
Limestone	328,029

RAILWAY BUSINESS FOR NOVEMBER.

The high tide of business in the United States continues to be reflected in the railway statistics compiled by the Bureau of Railway Economics from the reports of the railways to the Interstate Commerce Commission.

The returns for last November show an increase over November of the previous year, but do not maintain the ratio of increase displayed by the month of October; while operating revenues increased $122 per mile of line for the month, operating expenses increased $74, and net revenue only $48.33. Taxes were greater than for the previous November, amounting to $46 per mile of line. Operating income averaged $12.13 per mile of line for each day in November, an amount greater by $1.63 than for November, 1911. This is the entire amount available to the railways for rentals, interest on bonds, appropriations, and dividends.

For the five months of the fiscal year the net operating revenue per mile of line of the eastern railways, compared with the corresponding months of the previous year, increased 6.3 per cent.; that of the western railways increased 15.8 per cent., while that of the railways of the south increased less than one-tenth of 1 per cent.

For the eleven months of the calendar year the net operating revenue per mile of line of the eastern railways, compared with the corresponding months of the previous year, increased 4.8 per cent.; that of the western railways increased 7.4 per cent., while that of the railways of the south shows a decrease of 4.5 per cent.

LE BULLETIN DE L'ECOLE POLYTECHNIQUE DE MONTREAL.

L'Ecole Polytechnique, of Montreal, has deided to publish a monthly bulletin, beginning with January, 1913. This bulletin is published and edited through the co-operation of a number of the professors of the School. The first issue, which has just come to hand, is a thirty-two page, 6 x 9 in. book, handsomely bound in brown board. The bulletin is intended to help in furthering the interests of the graduates of L'Ecole Polytechnique in the School, and to follow and encourage scientific and engineering movements. The editorial and business offices are located at 228 St. Denis Street, Montreal.

THE TOWN OF MAGOG, MUNICIPAL HYDRO-ELECTRIC DEVELOPMENT.

BY A. C. DOCHERTY.*

The town of Magog inaugurated in January, 1912, its new hydro-electric plant on the Magog River, which supplies energy for its waterworks, and electric lighting system, also to the cotton mills of the Dominion Textile Company. This plant replaces the town's old development which had to be abandoned owing to its delapidated condition, and to its serious waste of water due to antiquated design, and non-utilization of the whole head.

The Magog River drains Lake Memphremagog, which is a considerable sheet of water, having a length of 30 miles and an average width of one mile and being fed by numerous small streams and springs. It affords a remarkable natural storage basin for regulation of stream flow which would be advantageous to all the powers on the Magog River, and to the St. Francis River, of which the Magog is a tributary. The flow at present fluctuates considerably, though the dam of the Dominion Textile Company, which controls the outlet of the lake, helps equalization to some extent.

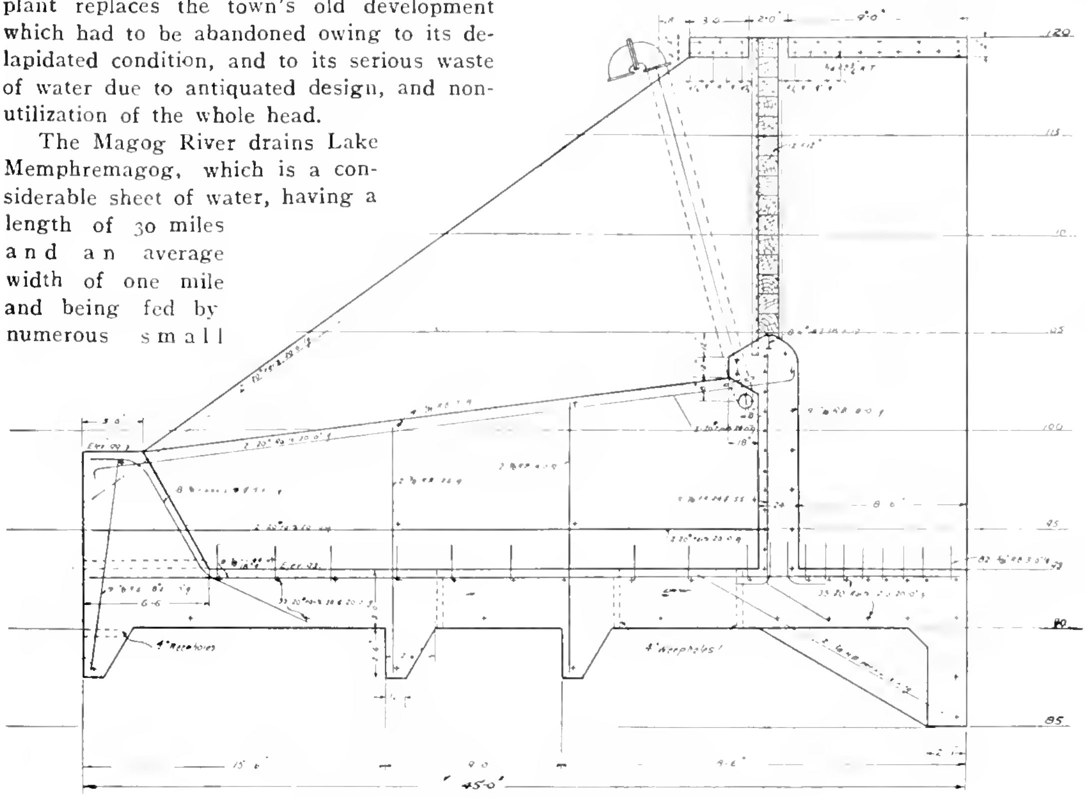


Fig. 1.—Cross-Section Through Sluiceways.

The Development.—The new plant is situated about two miles below the town, just below the site of the old plant, previously mentioned, and consists of a reinforced concrete power house, a reinforced concrete sluiceway, and earth embankment wing walls with concrete cores. Owing to the absence of rock, the design had to be suitable for an earth bottom, and erosion was guarded against by providing tumble-bays below the stoplog sluiceways in which the force of the falling water is absorbed by a water cushion, and by a timber crib which prevents any washing as the water leaves the tumble-bays.

The early spring of 1911 was spent in surveys and sinking test pits to obtain data for designing. The formation generally consisted of a top layer of gravel and boulders, and a heavy underlying stratum of hard clay. In March a wagon road was built into the site as well as a siding from the main line of the Canadian Pacific Railway. As the heavy blanket of snow disappeared clearing the timber and brush from the site, and flooded area was begun, and a start made on the first half of the cofferdam which was built around the site of the power house, work progressed rapidly so that by August 1st the river was turned through the turbine chambers and draft tubes, and the second part of the cofferdam, enclosing the sluiceway section, was begun. Simultaneously with the main part of the work, the concrete core walls and earth embankments were constructed, so that by October 30th the work was practically complete, except for its equipment, which was late in arriving, and it was not until January 20th, 1912, that current was turned on to the transmission line for the first time.

The Dams.—The concrete dam, 144 feet long, 35 feet high, 45 feet wide, at the base, is composed of six stoplog sluiceways and two blind sections, and is built with tumble-bays to break the force of the falling water, as shown in the section of the dam, Fig. 1. Four-inch weep holes are left in the floor of the dam for seepage and to prevent upward pres-

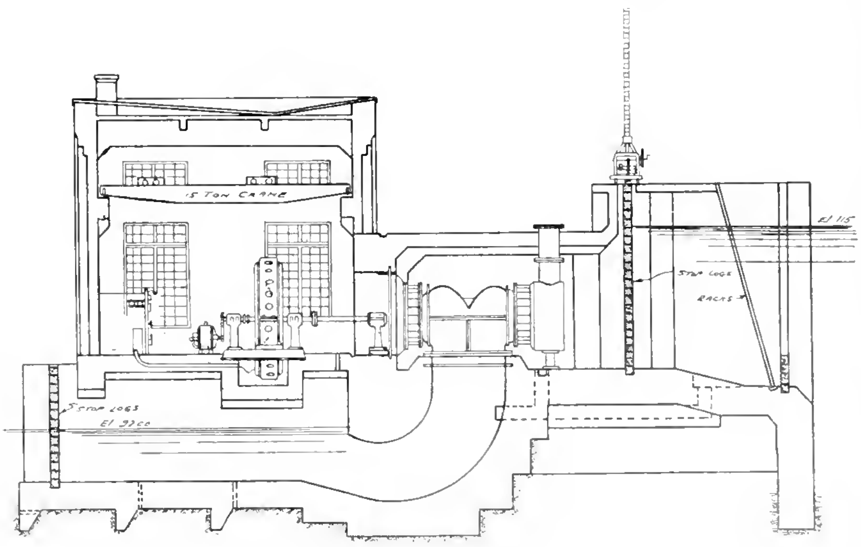

Fig 2.—Cross-Section Through Power House.

sure and a twelve-inch pipe is imbedded in each pier to prevent a vacuum behind the sheet of falling water. Two recesses, 12 inches by 14 inches, lined with a 12-inch channel are left in each pier to allow the timber stoplogs to slide in. The stoplog openings in the six bays are 15 feet high by 14

* Of T. Pringle & Son, Limited.

feet wide, and the stoplogs are removed and forced into place by a hand-operated travelling winch, which travels on rails built into the top of the dam. The winch operates all the stoplogs in both the dam and power house. A 12-inch reinforced concrete slab, nine feet wide, extends from pier to pier, to form a platform or runway.

The earth dam, which is 10 feet wide at the crest, is built with tapering concrete core wall extending into the hard pan; puddle is placed around the core, then sand and gravel, coarse gravel and boulders follow the puddle and rock fill around the toe. The slopes which are 2:1 are sodded to the water line.

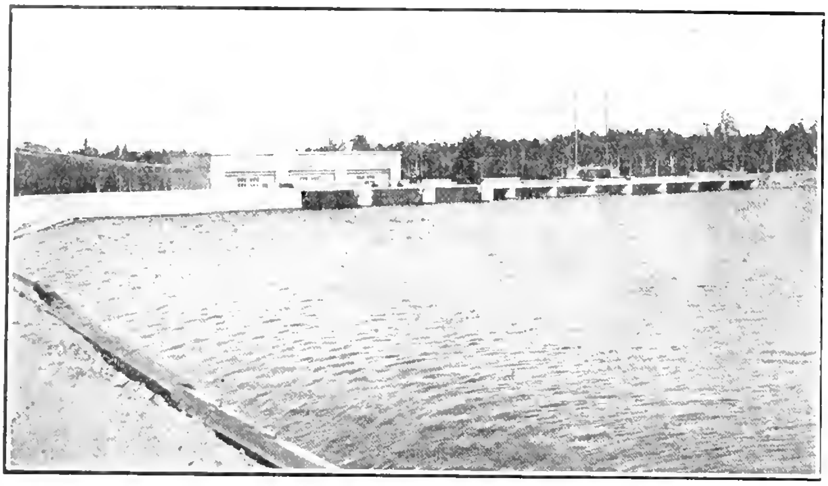

Fig. 3.

The Power House.—The entire power house, including the draft tubes, is built of reinforced concrete. Fig. 2 (cross-section) gives an idea of the construction, and Figs. 3 and 5 show the exterior. The structure is seventy feet long by twenty-nine feet wide and comprises three turbine chambers and generating room. Two sets of stoplogs are provided in the gate chamber to allow the racks to be repaired or cleaned out. The water leaves the turbines through an irregular-shaped draft tube, varying from a circle at the turbine to rectangular at the point where it discharges in the tail race. Cast iron manholes are built in the roof of the turbine chambers for inspection purposes. The power house is built for three units, two of which are at present installed—the third space being left for utilization when the flow regulation scheme for Lake Memphremagog is carried out. A fifteen-ton crane travels the lengths of the generating room. An excellent finish has been obtained on the concrete work, the general effect being good, and the large number of windows provides excellent lighting.

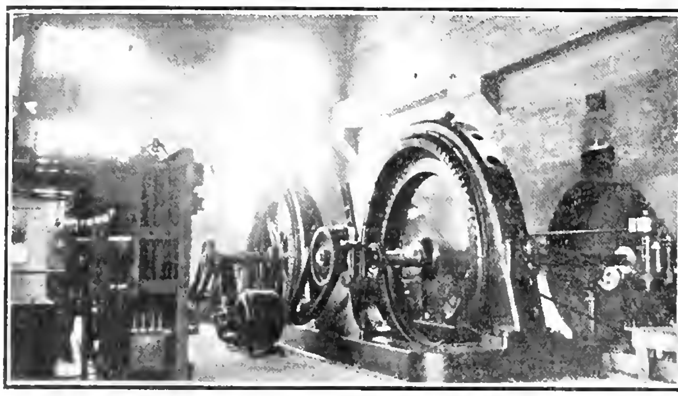

Fig. 4.

Fig. 5.

Hydraulic Equipment.—The present installation consists of two Escher Wyss water-wheels of the twin horizontal type, each of a rated capacity of 850 horse-power, at a speed of 150 r.p.m. under an effective head of 20 feet, with a guaranteed full load efficiency at full gate opening of 81 per cent. The turbine gates are of the wicket type, controlled by Escher Wyss governors. The regulation is 3 per cent. variation in speed on 25 per cent. change of loads and 15 per cent. on a hundred per cent. change on the basis of a fly-wheel effect of 225,000 lbs. feet.

Electrical Equipment.—This part of the installation has been designed to conform with the best modern practice. The generators are each of 500 kw. capacity and generate at 2,400 volts, 60 cycles, 2-phase, having a full load efficiency of 94.7 per cent. at 100 per cent. power factor and a regulation of 8 degrees from no load to full load, temperature rise of 35 degrees C. for 24 hours' run at full load. With a 25 per cent. overload the temperature rise will not exceed 50 degrees C. The outside diameter of the stator is 14 feet and the total weight of the generator is 50,000 lbs. The two exciters are shunt-wound each of 50 kw. capacity at 125 volts, 680 r.p.m., and are driven from the generator shaft by a silent chain, as shown in Fig. 4. Either exciter is capable of exciting both generators. The switchboard consists of six panels of marine finished marble, and is equipped with instruments and protective devices of the most modern type, to guarantee against breakdown and to ensure a constant and reliable service. There is one panel for each of the generators, one for the two exciters and two feeder panels. The generators are connected through double-throw oil switches to either of two sets of busbars. The exciters are also connected to duplicate busbars, so that the generator can take current from either exciter. The cables from the generators and exciters are run through the floor in fibre conduits to the switchboard. The outgoing cables are run along the wall in iron conduit and are protected by Garton Daniels lightning arresters.

Transmission Line.—The current is transmitted at 2,400 volts and the line is carried on 35-foot cedar poles, spaced 125 feet apart. There are three two-phase circuits of No. 0000 B. & S. bare aluminum wire, on three cross-arms, the wires being spaced 21 inches apart. Two of these circuits supply the cotton mills, the other going direct to the receiving station at Magog, a distance of about two miles.

Engineering.—The plant was designed and supervised by T. Pringle & Son, Limited, consulting engineers, of Montreal, Que., and Toronto, Ont. The power house and dam were built by the Bishop Construction Company, Limited.

The complete electrical equipment was supplied and erected by the Swedish General Electric Company, the transmission line by the Electric Repair and Supply Company, of Sherbrooke, Que., the hydraulic equipment by Escher Wyss and Company, of Zurich, Switzerland, and the stoplog winch by the Victoria Foundry Company, of Ottawa, Ont.

THE BRITISH COLUMBIA ELECTRIC RAILWAY.

One of the most active properties on the Pacific Coast is the British Columbia Electric Railway Company, Limited, of Vancouver, B.C., which has a number of important improvements under way, and which are noted in a recent issue of Electric Traction. Recently it arranged with the city of Vancouver for the construction of a new terminal for its Lulu Island interurban railway. This line extends from Vancouver through Point Grey to Eburne, from which point one division runs across Lulu Island to Steveston and another extends along the North Arm of the Fraser to New Westminster. Along this route settlement has been very rapid of recent years and a large commuter traffic is now carried on over the division. The line now enters Vancouver by a bridge spanning False Creek, terminating at a station at the water level. This location is inconvenient inasmuch as the station is located on low ground and passengers transferring to city lines must either walk up a steep hill or climb a spiral stairway to the level of the Granville Street bridge, over which run all the connecting city lines except one. The new arrangement proposed by the company is the location of an interurban terminal at the south end of the Granville Street bridge. By this plant interurban passenger cars will not be obliged to cross the False Creek bridge but will be brought into the city directly on a level with the Vancouver city cars. The terminal will also be of advantage to the city system as it is located near Fourth and Granville Streets, an important city transfer point.

The terminal will consist of two wings, each about 40 by 28 feet in size, connected by a covered passageway 25 feet in width, ample to accommodate the traffic from the interurban lines to the city system. In the south wing will be located the ticket office, agents' office, etc., while in the opposite wing will be a general waiting room and separate ladies' room. The terminal being located on made ground will be of wood construction. The plans call for a handsome structure costing between $30,000 and $40,000. The trackage arrangements provide a terminus for the Lulu Island cars on the west side of the station.

The management of the company is also providing for the comfort and convenience of the motormen and conductors employed on its Vancouver lines by the construction of a five-story club building at the corner of Main and Prior Streets, Vancouver. This location is directly opposite the principal car houses of the company in the city.

The building will have a frontage of 25 feet on Main Street a depth of 60 feet on Prior Street. The Prior Street frontage to the rear of the block is owned by the company and in the plans of the building arrangement is being made for the extension of the block should the need arise.

On the first floor will be located the general waiting room for the men and offices for the station master and inspectors. On the second floor will be a large billiard room which will be furnished with billiard and pool tables. On the third floor will be located the reading room and about one-half the floor space will be used for lockers. The fourth floor will be divided entirely for lockers, this accommodation in connection with the third floor providing lockers for over 500 men. The gymnasium will be located on the fifth floor, the entire flat being left free of obstruction as far as possible. In this room will be installed a complete set of gymnasium apparatus. The upper floor of the building will be reached by an elevator as well as a winding stairway. Lavatory accommodations are provided on each floor.

The block will be of brick construction, the frontage being trimmed with terra cotta. The estimated cost is between $30,000 and $40,000.

The management of the company recently announced that a contract had been closed with the Preston Car and Coach Company, of Preston, Ontario, for 65 city passenger cars. This is the initial order of the company for 1913 delivery. The cars are to be of single-end type and 44 feet in length. The specifications are still subject to minor changes but the cars will be of the latest model throughout. Delivery will be made during the months of April and May.

The company expects soon to operate its interurban line from Victoria north through the Saanich Peninsula, 22 miles in length. For this line orders for rolling stock have been placed as follows:—Two baggage and express cars from the Niles car and Manufacturing Company and six passenger cars from the St. Louis Car Company. For freight service 15 flats and 25 box cars have been ordered from the Seattle Car Company and two 45-ton locomotives will be taken from the mainland system for use on the new interurban line.

For service on its mainland freight lines, the company has recently ordered 25 box cars from the Seattle Car Company and five 50-ton locomotives from the Westinghouse Electric and Manufacturing Company, of Pittsburg. Other rolling stock recently ordered consists of two snow-sweepers from the Ottawa Car Company and six Hark-Otis steel dump cars.

During December full delivery was made of the 24 interurban cars ordered by the company from the St. Louis Car Company last summer and this equipment is now in service. The initial shipments have also been made by the J. G. Brill Company from its Philadelphia shops on the large order for city passenger cars recently placed with that concern.

In announcing its contract with the Preston Car Company, the management of the British Columbia Electric Railway stated that it was not the intention of the company to abandon the car building work in connection with its New Westminster shops. It was stated that the schedule for new rolling stock for all lines of the system for 1913 is now being prepared and in this program ample work would be allotted the New Westminster plant. At these shops is now assembled and finished a shipment of 25 steel city passenger cars which have been constantly arriving on an order placed some time ago in the old country.

LAKE SUPERIOR CORPORATION.

The Lake Superior Corporation propose to expend a large sum of money—$12,000,000 is mentioned—to extend its plant at Sault Ste. Marie, Ontario. Mr. J. F. Taylor, vice-president and managing director of the company has been in New York in consultation with his associates, and states that the company has determined to meet the Canadian demand for steel rails. Sixty-seven acres of land have been purchased for the proposed extensions. Another blast furnace and a new steel rail mill will be erected and large additions made to the open heart hand coke plants.

Mr. Taylor states that when the new works are completed the corporation will be in a position to turn out six hundred thousand tons of steel rails per year, or a daily average of two thousand tons, and he estimates that that will be sufficient to meet the requirements of the country. The maximum output of the present steel mill is about three hundred and sixty thousand tons a year.

STORM WATER DISCHARGE.

By R. O. Wynne-Roberts* and T. Brockmann.†

The subject of storm water discharge has been dealt with in two very instructive papers, one by Mr. Lloyd Davies, the city engineer of Alexandria, Egypt, and the other an expansion of the first, by Mr. Wallington Butt. Mr. Wynne-Roberts, however, in collaboration with Mr. T. Brockmann, has made a study of the matter, and purposes to present a series of articles, of which the following is the first, to explain the several factors that affect the solution of the above problem. As the theme is being developed, Mr. Wynne-Roberts proposes to show in what manner the calculations of storm water discharges can be made more comprehensively and accurately than, he is aware, has hitherto been suggested in the English language. He, however, does not claim any originality of the method to be described later on, as it is an adoption of an idea put forward by an eminent German engineer, the late Prof. Frühling, of Dresden. —[Editor.]

The engineer who is called upon to design sewers has first of all to decide whether it is advisable to adopt the "combined" system or the "separate" system. In the former the ordinary sewage and rainwater are conveyed by one common sewer, whereas in the latter case they are conveyed by separate conduits.

Whichever system is adopted, if the sewers are constructed practically water-tight, it will not be a difficult matter to calculate the probable volume of ordinary sewage, for it must largely depend on the consumption of water for various purposes. In Europe this quantity averages about 30 gallons per head per day, but in Canada and United States, for reasons which need not be gone into here, it ranges from about 40 to over 200 gallons per head daily.

The quantity of ordinary sewage will necessarily vary during different hours of the day and in different seasons of the year. The range of fluctuation in volume of sewage to be dealt with will approximately be from about 40 per cent. below to about 60 per cent. above the mean daily flow.

When, however, the engineer has to attack the problem of providing sewers to drain away storm water, he is confronted by many perplexing considerations. The quantity to be drained away per unit of time is generally vastly greater than the volume of sewage, so much so, that the latter can oft-times be ignored when calculating the dimensions of combined sewers.

While ordinary sewage has to be disposed of in volumes ranging within more or less definite limits, the quantity of storm water varies so enormously, it is so erratic in its periodicity, and is dependent upon so many variable factors, that it is not surprising some eminent authorities who have been extensively quoted, have abandoned all attempts to establish a general formula for this purpose.

This subject has engaged the attention of many capable engineers in Europe and America, some of whom have deduced formulæ by which they considered it was possible to arrive at the probable volume of storm water to be provided for, with sufficient accuracy.

The following are some of the formulæ which have been extensively quoted:—

Bürkli-Ziegler:

$$Q = R \times C \times \sqrt[4]{\frac{S}{A}}$$

McMath:

$$Q = R \times C \times \sqrt[5]{\frac{S}{A}}$$

$$Q = R \times C \times \sqrt[5]{S \times A^4}$$

Q = Cubic feet per second per acre reaching sewers.
Q = Cubic feet per second from the whole area drained.
R = Average rain during heaviest rainfall, in cubic feet per second per acre, varying from 1.75 to 2.75.
C = Constant, 0.75 for paved streets, 0.31 for rural districts, average 0.625.
A = Area of district drained in acres.
S = General fall of area per thousand.

Hawksley and Bazaloette:

$$\text{Log } D = \frac{3 \text{ Log } A + \text{Log } N + 6.8}{10}$$

D = Diameter of circular sewer in inches, to carry off a rainfall of one inch per hour.
A = Number of acres drained.
N = Length of sewer having a fall of one foot.

Kuichling:

$$Q = A \times a \times t \times (b - c \times t)$$

Q = Discharge in cubic feet per second.
A = Area drained in acres.
a, b, c = Empirical constants which vary for different localities.
t = Time required for the concentration of storm water at the outlet.

Lloyd-Davies:

$$Q = (60.5 \times \frac{60}{Tc} \times R) \times Ap$$

Q = Cubic fet per minute.
Tc = Time of concentration, i.e., time of flow through longest line of sewers in district in minutes.
R = Rainfall in inches during Tc.
Ap = Percentage of impermeable area in acres.

If the reader cares to solve any problem concerning storm water by the foregoing formulæ, he will find that the assumptions adopted by the different authorities are far from being uniform and the results obtained will be very dissimilar.

It is interesting as a matter of history, to note how Bürkli-Ziegler's formula was established. About the year 1878 he was city engineer of Zurich and during his term of office serious floods occurred, causing destruction, which was followed by litigation for compensation.

The information as to the intensity of rainfall and the quantity discharged into the sewers, was at that time very meagre and unreliable, and this induced him to take up the matter to see if some formula could be found to suit his requirements.

He found that Hawksley had assumed a rainfall of one inch per hour, which is equivalent to 70 litres per second per hectare, and had constructed a formula which, in metric terms, had the following expression:

$$D = 0.32 \sqrt[10]{\frac{A^3}{S}}$$

D = Diameter of pipe in metres.
A = Area in hectares.
S = Slope of area in 1,000.

* M. Inst. C.E., F. R. San. Inst., Consulting Engineer, Regina.

†Dipl. Ing. (Berlin), Civil Engineer, Regina.

Etylwein also had brought out his forumla for ascertaining the size of pipes, which was:

$$D = 1.2 \times \sqrt[10]{\frac{A^4 \times q^4}{S^3}}$$

q = Volume of discharge per second per hectare in cubic metres.

A and S were the same as above.

By combining the two formulæ, Bürkli-Ziegler obtained the value of "q" corresponding to the rainfall assumed by Hawksley. Thus:

$$D = 0.32 \times \sqrt[10]{\frac{A^3}{S}} \text{ equal } 1.2 \times \sqrt[10]{\frac{A^4 \times q^4}{S^3}}$$

$$q = 0.037 \times \sqrt[4]{\frac{S}{A}}$$

Reducing this to litres per second per hectare he got

$$q = 37 \times \sqrt[4]{\frac{S}{A}}$$

The ratio between the discharge and the quantity of rain fallen, which was sought for by Bürkli-Ziegler, was found thus:

$$\frac{\text{Volume of discharge}}{\text{Rainfall}} = \frac{Di}{Rn} = \frac{37}{70} \times \sqrt[4]{\frac{S}{A}}, \text{ say } 0.5 \times \sqrt[4]{\frac{S}{A}}$$

$$Di = 0.5\, Rn \times \sqrt[4]{\frac{S}{A}}$$

This is the classic formula deduced by Burkli-Ziegler. Considering 0.5 as the factor of impermeability denoted by "P" it then takes the form in which it has been so extensively published in America, etc.,

$$Di = P \times Rn \times \sqrt[4]{\frac{S}{A}}$$

Of the foregoing formulæ, the last (Lloyd-Davies) is the most advanced, but is does not satisfy all the conditions, as will be shown later on. With regard to the others, it can be stated that they are inadequate and no longer up-to-date.

These formulæ (excepting Lloyd-Davies') are unsatisfactory inasmuch as it is assumed that the discharge is constant, regardless of the shape and configuration of the drainage area, and the velocity of the flow in the sewers.

Lloyd-Davies' formula is an advance on the others, for it takes into consideration the above mentioned factors, which are ignored by the others, but which, nevertheless, are important, as they actually influence the discharge of the storm water. But he and Mr. Wallington Butt, who have read interesting papers on this subject, assumed that the entire area must be contributory to the flow in the sewers, before the maximum discharge is attained. This assumption, however, must be controverted, as it does not suit all conditions.

The principal factors which influence the discharge of storm water are:

1. Rainfall intensity.
2. Impermeability of the surface of the drainage area.
3. Retardation, which depends on the shape, extent, and configuration of the drainage area and also on the velocity of flow in the sewers.

1. Rainfall Intensity.—The annual rainfall in different parts of any country varies considerably. The mean annual precipitation over a long period, in parts of Prairie Provinces, for instance, is about 18 inches, but in other parts it is much less. In the semi-arid parts of the United States it is under 10 inches, whilst in the Canadian Rockies it must be many times as much. On Table Mountain, Capetown, the average yearly rainfall over a certain area is nearly 70 inches, but in the city, which is only four miles distant, it is 30 inches. In the Berg River Hoek watershed, which is about 50 miles inland from Capetown, the mean annual precipitation is about 120 inches, whilst in the valley, less than ten miles away, it is only 36 inches.

The mean rainfall in Germany is about 26½ inches, although near Berlin it is 24 inches and near Basel 33½ inches.

The rain, moreover, does not fall in convenient, uniform showers, but often in erratic torrential downpours, with very great intensity, during more or less short periods.

In New England, a rate of 3.6 inches an hour, continuing for 5 minutes may be expected every year or so, a rate of 2 inches continuing for 20 minutes; 1½ inches for 30 minutes, and 1 inch in one hour (Folwell).

(To be continued).

LOCATING A RAILWAY LINE.

By J. A. Macdonald.*

When surveys are to be conducted in a country which is timbered and little known, it is, in the long run, a great saving of time and money if it is practicable to have the engineer who is to have charge of the survey, accompanied by a good assistant, and say, half a dozen or more men, go over the country as best he can, running rough compass lines, using a micrometer, pacing or estimating for distances, taking barometrical altitudes, and generally becoming acquainted with the nature of the country and principal difficulties he may expect to have to overcome. Having gone over the whole of the section allotted to him, and thoroughly explored the country for several miles on either side of his rough compass line, he will have naturally formed some idea of the best route to be followed and save the cost of a large party running instrumental lines that may prove, after weeks of hard labor, utterly impracticable through running into some unforeseen obstacle. The engineer in charge of work of this character should be one who has had considerable experience in a timbered country, able to find his way anywhere, and not afraid of being lost. He should be able to establish his latitude and approximate longitude by observation though, owing to the difficulty in carrying a reliable chronometer, the latter is seldom to be relied upon. On reaching his point of departure his aneroid barometers, of which he should have at least two, or better four, having all been previously compared and rated, he will assume a datum for elevation for his work, and all altitudes should be reduced to that datum. By arranging the movements of his party he can provide that one barometer will always be stationary, and if a half-hourly record of its readings is carefully kept all altitudes taken by the party in the field can be reduced to one datum, the party having kept record of the time at which the observations were made. As is well known, such barometrical altitudes cannot be explicitly relied upon, but with care and good barometers it is surprising what close approximation to the true altitudes can be obtained. My experience has been that the aneroid barometers best suited for rough work are those about two and a half inches in diameter, divided to read five feet. The range of such barometers does not generally exceed two thousand eight hundred feet, but are much less

* Late of the staff of the National Transcontinental Railway.

liable to get out of order than the larger ones, which are supposed to read verniers to one foot.

Having thoroughly explored the country through which he is to operate, the engineer-in-charge selects a route for his preliminary line, and having been joined by his transitman and the rest of the party he proceeds with the running of such a line. If the country is rough and unbroken a transit should be used, but if tolerably level a picket line run by the aid of field glasses, the angles being turned with a transit or box sextant is generally the most rapid method and sufficiently accurate for preliminary purposes if the line is checked by compass bearings. The chainage should be done with a light steel chain.

Having assumed a datum for elevation, the levelling should in all cases be carefully done and checked wherever practicable, bench marks being established at least every half mile. Cross sections should be taken by the topographer as frequently as the nature of the country may require, to enable him to show contour lines for every five feet of elevation on either side of the line for considerable distances. As the through levels are not in any way affected by the cross-section work, these sections can be taken with sufficient accuracy with a good hand level, the distance right or left being measured with a chain or tape. It is a good practice to insist that the field notes of all instrument men be plotted up by the men who made them each night as the work progresses; this will save time and avoid many errors.

Having completed his preliminary line, the engineer-in-charge lays down on his plan, with the aid of contour lines, a proposed location and proceeds to stake it on the ground, the levels being checked with those of the preliminary line and bench marks established every thousand feet.

Having completed his first location and made any revisions that may have occurred to him, the engineer who has been in charge of such work should be moved on to other work and a new man put in charge of the party. This new man should, before taking charge of the party, be furnished with the plans and the profiles and given ample time to go out of the lines run by his predecessor. He may or may not be able to improve on the previous line, but in any case the judgment of two in place of one is obtained on final location.

In conclusion the commissariat for the survey party today is a very different matter from what it was thirty years ago. Formerly, if a party was well supplied with the necessaries of life, in the shape of bacon, beans, flour, tea, and sugar, it was all that they expected, whereas to-day, the addition of canned meats, dried fruits, vegetables and canned goods generally has added much to the variety of food supplied, but one thing that in the old days contributed more than others to the well-being and comfort of a party is still the same, namely, a good cook.

FACTOR OF SAFETY IN REINFORCED CONCRETE STRUCTURES.

In discussing the factor of safety in reinforced concrete structures, Mr. R. G. Clark, in the January issue of Ferro-Concrete, gives an interesting discussion. Mr. Clark says that the factor of safety in a reinforced concrete structure has generally been denoted by the ratio of the maximum working stress in the steel to the ultimate strength of the steel. For example, assuming that the working stress is 16,000 lb. per square inch, and the ultimate strength is 64,000 lb. per square inch, the factor of safety would be 4 by this theory.

Others, again, take the view that if the steel is stressed beyond the elastic limit the structure has, to all intents and purposes, failed, and, taking this line of reasoning, the factor of safety is expressed by the ratio of the maximum working stress to the elastic limit of the steel. Assuming the working stress at 16,000 lb. per square inch, and the elastic limit at 45,000 lb. per square inch, we then have the factor of safety reduced to about 2.75. This, however, is purely a theoretical calculation which deals with the steel only, but in any scientifically designed reinforced work we know that the concrete shares with the steel an equal responsibility concerning the stability of the structure, so that before the factor of safety can be accurately determined it is essential to see that the concrete also has an ample margin of safety.

The designer, in the matter of the quality of the steel, can safeguard himself by specifying that the British Standard Specification must be adhered to, but unfortunately no such standard is available for the concrete.

It is true that as far as the cement is concerned we have the assistance of the British Standard Specification as regards quality, but in the matter of the quantity of cement the greatest latitude is allowed when we have mixtures varying from 1:4 to 1:9 parts of cement to aggregate.

Dealing with the aggregate used for the concrete, this is more or less controlled by the materials available in any given district, and here again, to make matters worse, much difference of opinion exists as to suitable concrete materials. Very often the selection is left to the contractor, whose natural aim is to get something cheap in order to outstrip his competitors, and as the designer is generally many miles away he may not know of this arrangement, and the prejudicial effect it may have upon the factors of safety provided by his elaborate calculations.

In the past it cannot be denied that the concrete has been more or less overshadowed by the advocates of particular kinds of reinforcing steel, but the concrete in reality needs more attention than the steel, not only because of the reasons stated above, but also for the reason that the lifetime of the structure depends upon the efficient protection of the steel from corrosion. Therefore, as we assume in assessing the factor of safety of the steel that it will not deteriorate, then every care must be taken to protect it, and this can only be done by having the concrete composed of the best materials available, carefully graded and mixed with a generous quantity of the best cement.

It is by no means uncommon for competitors to state their calculated factor of safety, and it is interesting to note that for precisely the same work the factors of safety given by various firms vary from 4 to 9.

How the latter figure is arrived at is frequently a mystery, especially in cases where the firm submitting the lowest tender quote the highest safety factor.

It is obvious that something should be done to standardize the method of calculating the factor of safety, and that any method adopted should include due consideration of the strength of the concrete mixtures. It is altogether unfair to fix a limit of working stress on the concrete unless inquiry is also made into its constituent parts, as the limit may be much too low for some mixtures or too high for others.

In conclusion, it must be pointed out that the actual factor of safety is much above the calculated value if the best materials are used, but it should be remembered that the calculated factor of safety is only used for purposes of comparison. With a good concrete and steel efficiently protected the factor of safety increases as time progresses, owing to the fact that the concrete increases in strength with age, and in this respect affords a striking contrast with structural steel, timber or brickwork, which are at their best when new.

WATER RAM RESULTING FROM THE OPERATION OF A HYDRAULIC ELEVATOR.

About three years ago the Northeast Harbor Water Company experienced difficulty with fluctuations of water pressure arising from the operation of a hydraulic elevator. The company served notice upon the proprietor of the building in which the elevator was installed, to install a tank to supply water through a 4-in. service pipe for the operation of the elevator instead of drawing water for that purpose directly from the 8-in. street main. The proprietor objected to installing tanks. The company notified him that his water supply would be shut off unless he complied with their requirements. At that point the proprietor brought suit in equity to enjoin the company from shutting off his water. The result of the case, which was tried in April, 1910, may be summarized briefly as follows: The court decided that the use of water for a hydraulic elevator was a domestic use within the ordinary meaning of that term. On this ground it ruled that the company was obliged to furnish water for a hydraulic elevator, if the proprietor so desired. The court ruled, however, that the company was justified in asking the proprietor to install a tank of suitable capacity to relieve the street mains from the water ram caused by operating the elevator by direct pressure from the mains. The court decided, further, that the requirement of the company was justified since its order was given to protect its own property and to safeguard the interests of other water consumers on the same main pipe line. The injunction was not granted and the company was left free to enforce its ruling unless the proprietor substantially conformed to the requirements it laid down.

Mr. Charles W. Sherman, principal assistant engineer with Metcalf and Eddy, of Boston, was called as an expert witness by the proprietor. The results of tests made by Mr. Sherman in preparation for his testimony as well as the principal figures submitted by the water company, were given in Mr. Sherman's paper before the New England Water Works Association at the annual meeting of the association which was held in Boston on January 8, 1913. The information here given is taken from Mr. Sherman's paper.

The hotel was supplied by a 4-in. pipe, 300 or 400 ft. long, leading from an 8-in. main supply pipe at a distance of some two or three miles from the pond from which the supply is taken. The hydraulic elevator—the only one in town—is of an old type and has a total lift of about 32 feet. The travel of the plunger is about 4 feet, and its diameter is 22 inches. It was found that the elevator valve was made to open or close a series of holes, with the intention of making the opening or closing rather slow; and that it was necessary to overhaul 4½ ft. of valve rope to open or close the valve, or 9 ft. to reverse the elevator. The static pressure at the hotel was about 40 lbs. per sq. in., and a relief valve set at 45 lbs. had been installed near the elevator.

Nobody seemed to know just how long it took the elevator to make a trip, but it was conceded that it could hardly have been less than 30 seconds. Assuming this to be correct, the 22-in. plunger traveled about 4 ft., and consequently the displacement was 79 gals. in 30 seconds, or the flow was 158 gals. per minute. This flow corresponded to a velocity of less than 3 ft. per second in the 4-in. pipe, which is certainly not an excessive velocity. If this could have been checked instantaneously the resulting water ram would have been considerable, but it would obviously have required an appreciable time to overhaul 4½ ft. of valve rope to shut off the water.

The data available before the water company had presented its case were not sufficient to enable Mr. Sherman to make an estimation of the increased pressure which might have resulted from the operation of the elevator, to which he would care to testify. In order to get some information an experiment was made, through the courtesy of the superintendent of the waterworks at Ellsworth, Maine, where the court was in session. Here a place was found where there was a 4-in. pipe, some 400 ft. long, supplying a locomotive standpipe, where the normal pressure was about 68 lbs. per sq. in. This branch, like that at Northeast Harbor, was from an 8-in. main leading from the reservoir at a considerable distance. No method was discovered of drawing water, or of opening and closing the valve, at the same speed as with the elevator, so it was determined to make the test as severe as possible. The pressure gauge was attached to a house service pipe about 150 ft. from the locomotive standpipe, and the standpipe valve was opened wide, as rapidly as possible, left open until a condition of steady flow was obtained, and then closed as rapidly as possible. Mr. Sherman estimated the maximum velocity in the 4-in. pipe at not less than 10 ft. per second. The time of opening the 4-in. valve was 30 seconds, and the time of closing was 20 seconds. The pressure dropped almost immediately upon starting the valve from 68 to 28 lbs. per sq. in., or to 41 per cent. of the normal. At the instant of closing the pressure gauge registered 134 lbs. per sq. in., or 202 per cent. of the normal.

Mr. Sherman considers that this maximum pressure is not great enough to be dangerous to any well-constructed pipe system, although he believes that the sudden fluctuations would doubtless be annoying at times.

The officers of the water company presented gauge readings showing what the actual fluctuations had been in various parts of town. The significant figures, as taken down during the testimony, are as given in Table I.

Table I.—Pressures Observed at Various Places During Operation of Hydraulic Elevator.

Pounds per square inch			Per cent. of normal	
Normal.	Highest.	Lowest.	Highest.	Lowest.
56	75	40	135	71
58	60	35	104	60
55	62	32	112	58
32	40	10	126	31
32	50	10	156	31
60	80	40	133	67
58	85	35	147	60
55	75	35	136	63
54	70	25	128	46
51	70	28	137	55
30	50	10	167	33
30	50	8	167	27
28	60	10	213	35

The figures given in Table I. show that in general the operation of the elevator caused a drop in pressure ranging from 40 per cent. to between 60 per cent. and 70 per cent. when the valve was opened, and an increase in pressure, or water ram, amounting to from 30 to 50 per cent. of the normal pressure under ordinary circumstances, and sometimes running up to about 100 per cent. increase in pressure.

These results confirm in a general way the conclusions reached by Mr. Sherman from the experiment described above—that the pressure might drop about 60 per cent. below normal when the valve was opened, and rise to a maximum of about 100 per cent. above normal at the moment of closing the valve. These fluctuations are sufficient to cause annoyance, but where the normal pressures are as low as in the cases cited, should not be dangerous to the pipes.

Mr. Sherman points out that none of these results can be applied to conditions differing materially from those here described, but they may serve to give some indication of the extent of the water ram that may be experienced in a small waterworks system from the rapid closing of valves or fire hydrants.

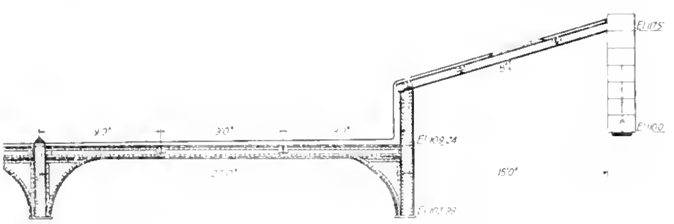
THE OTTAWA PASSENGER TERMINAL TRAIN SHED.

Three types of train shed are in general use, the long-span, high-arched roof type, the open platform canopy type and the short-span, continuous low-roof type.

The following comments and abstract from an article in a recent issue of the Engineering Record in which the Jersey-Central freight shed and the Ottawa train shed were described. The details which deal with the Ottawa shed are here abstracted.

The long-span, high-arch roof type, while having an imposing appearance, cannot be easily ventilated, and the gases not only are an annoyance to passengers but attack the steelwork, necessitating frequent painting, which is expensive because of the height of the structure. Even then the life of the shed rarely exceeds 20 years. The soot moreover impairs the lighting and the inaccessibility of the sky-lights makes their cleaning difficult. As a consequence of the frequent cleaning of skylights and painting the maintenance costs are high. The width of the shed is limited by the moderate length of span of arch roof trusses, and with increasing business, additions to the trackage are not possible without building a new shed or housing the new tracks beneath a structure having no architectural unity with the main shed. The first cost is also high, and increases much more rapidly than in simple proportion to the width of the structure. Its erection is expensive, requiring elaborate falsework.

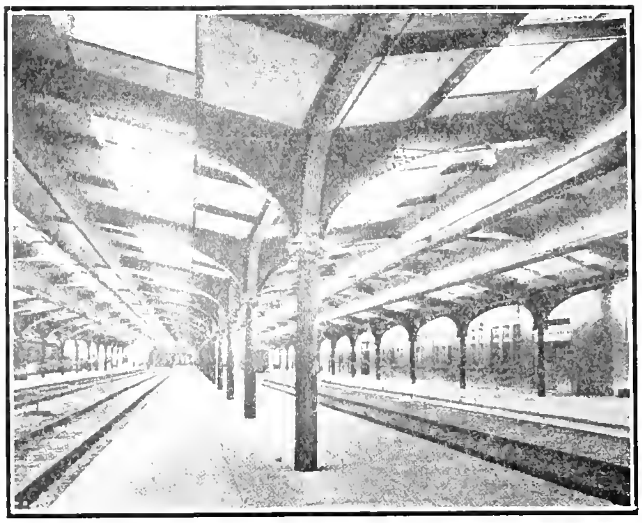
The canopy shed is simple and inexpensive, is adaptable to future longitudinal and transverse extension and is accessible for maintenance and repairs. It does not retain locomotive gases, and the ventilation is therefore good, and the



Part of Section Through Ottawa Train Shed and Head House.

corrosion a minimum. Besides it affords unobstructed light and lends itself to convenient and cheap methods of erection. It does not, however, offer a sufficient shelter from wind or driving rain or snow. The roofs extend beyond the platforms only a few feet, at most, and consequently the tops of the cars act as chutes to carry rain from driving storms on to the platforms.

The short-span, continuous low-roof type, represented by the Bush train shed, full details of which are given in this article in connection with a description of the shed now being built at Jersey City for the Central Railroad of New Jersey, has longitudinal rows of columns carrying short-span transverse roof girders that support a continuous roof surface sheltering the whole area of the shed. By means of a concrete duct over each track, gases, smoke and cinders are carried outside at once, and in consequence there is neither annoyance to passengers nor deleterious action on the steelwork. The ducts are so deep that wind, rain and snow cannot drive into the shed. The skylights are readily accessible, thus insuring frequent cleaning, with consequent good illumination in the shed. It should be noted that deposits of soot on the under side are entirely avoided, since the smoke does not enter the shed. Painting is likewise facilitated, and



Interier View of Ottawa Train Shed.

since, in addition, no more painting is required than for ordinary steelwork, this item of train-shed maintenance cost is reduced far below that for a high-arch shed. The freedom from gases gives these sheds practically unlimited life, provided they receive ordinary maintenance and care.

In first cost the shed is more economical both in material and in erection. The steel required per square foot of shed is not more than half that needed for a high-arch shed. Instead of using costly falsework, as is required for the high sheds, the erection is accomplished by an ordinary derrick car, and by taking one bay at a time the work can proceed without interrupting traffic. Should increased trackage be needed there is no difficulty in adding more bays of the same design, thus preserving the architectural unity.

The Ottawa train shed is of the Bush type and has recently been completed for the Grand Trunk Railway Terminal at Ottawa, Canada, Mr. H. R. Safford, chief engineer, and Mr. Wm. McNab, principal assistant engineer. It is 533½ feet long and 163½ feet wide and has seven tracks. The principal structural differences are in the use of a concrete longitudinal sidewall along one side of the shed, provided with movable windows for side ventilation and the substitution of riveted girders for I-beam longitudinal girders connecting the tops of the columns. The passenger platforms between the tracks consist of solid concrete slabs laid on the surface of the ground, and the columns are supported on piers without pile foundations.

A NEW MONTHLY MAGAZINE.

The first issue of "Steam Machinery," published by the Steam Machinery Publishing Co., of Duluth, Minn., has just come to hand. The magazine is devoted to descriptions of machinery and methods, and this first issue presents a most pleasing typographical appearance. In the editorial announcement the following statement of its purpose is given: "We believe the times are ripe for a frivolous magazine with a serious purpose. We believe this to be the sub-conscious spirit of these times. To laugh a lot; to work a lot, and to live like Billybedarned!"

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of the CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MARINE AND MINING ENGINEER, THE SURVEYOR, THE MANUFACTURER, AND THE CONTRACTOR.

JAMES J. SALMOND, MANAGING DIRECTOR

CONTENTS OF THIS ISSUE.

AN EXAMPLE OF COUNTY COUNCIL CONTROL.

A good example of the manner in which engineering and construction work is handled by municipal bodies is shown in the management of the good roads system in the county of Welland. At the last meeting of the County Council a by-law was passed appointing Mr. George Ross, of Welland, as engineer in charge of the work in place of Mr. J. C. Gardner, of Niagara Falls.

A year ago Mr. Gardner was appointed as engineer for the county good roads system, and three foremen, who were conspicuous more for their political activity than for their ability as construction men, were placed on the work. The work of organization and the buying of new machinery and supplies took up a good deal of time, and a great deal of time was wasted, in addition, by the council in quibblings and dickerings over what should be done. Instead of the work being placed under a small executive committee of the County Council, the whole Council acted as a committee on the work, with the result that much valuable time was lost.

Instead of this year giving Mr. Gardner full control of the situation by allowing him to appoint his own foreman and men, and profiting by the experience of last year, the Council have removed Mr. Gardner to make way for another man. Such injustice and lack of business capacity is typical of bodies of men, made up as county council is. Where political pull and local jealousies and prejudices are allowed to interfere with the carrying on of public work, inefficiency and waste is always the result.

CLASSIFICATION OF COAL LANDS.

It is a widespread popular impression that if coal is found outcropping on a tract, the land is coal land, and that if no coal is to be found outcropping the land is non-coal land. If this were true, probably more than one-half of the coal produced in the country (in some States more than 95 per cent.) would be coming from mines not on coal land.

As an illustration, 196 mines in Indiana in 1908 produced 11,997,304 tons of coal. Of these 196 mines, fifteen were working the coal from the outcrop, and produced 400,733 tons, or a little over 3 per cent. of the total. The rest was mined from land, the surface of which showed no coal. In Illinois the percentage is still less, and in both States the average production of the mines working on the outcrop is small, compared with the average of all the mines. The percentage of coal worked from the outcrop is greater in Pennsylvania, West Virginia, and the southern Appalachian States than in the two just cited, but not much, if any, greater in the Michigan field, the western interior field, or some others of the large fields of the country. It is true that in many of the fields when first exploited mines were mostly driven in on the outcrop, but for two reasons that condition has greatly changed: First, the coal close to the outcrop has been mined out; and second, after a time it has been found to be cheaper to mine the coal from shafts sunk to the bed from a point some distance back from the outcrop than to haul the coal, water, and waste up the slope of the bed as it pitches into the ground.

If, therefore, any producing coal field is examined there will usually be found a belt of outcrop in which the coal-bearing rocks rise to the surface of the ground, and outside of that belt an area, which may amount to thousands of square miles, where the coals are all below the surface, and the surface rocks may even be of en-

tirely different age, and perhaps not coal-bearing at all.

If in any tract a bed of coal of workable thickness outcrops it evidently does not underlie all, and may underlie only a small part of the tract, and to that extent the land is not coal land, so that it sometimes happens that a bed of coal outcrops or is exposed on a given tract, and yet underlies so small a part of the tract that it would hardly be fair to consider the whole tract as coal land.

In Indiana shafts have been sunk to coal beds at a depth of 250 feet without any preliminary drilling where the coal bed did not outcrop nearer than fifteen miles, and many of the mines of Illinois are twenty-five to fifty miles from the nearest outcrop of the coal they are working.

In classifying land as to its coal character a few general principles are involved:—

1. If the land is known to be underlain only by groups of rocks known nowhere to contain coal, the land is assumed not to be underlain by coal and to be non-coal land.

2. If land is known to be underlain by one or more groups of rocks known to contain workable beds of coal, and a study of the dips shows that those groups are not too deep for the coals they contain to be worked, the land may be presumed to be coal land.

In nearly all cases where public lands have been withdrawn pending examination and classification it is known or believed that the land is underlain by groups of rocks known elsewhere to contain workable beds of coal. In probably a majority of cases it is also known, or later examination demonstrates, that coal does not outcrop on most of the land withdrawn, but underlies it, perhaps at a considerable depth.

Given, then, an area of public land withdrawn for examination and classification, under what conditions will it be classified as non-coal land?

1. Detailed examination may show that the coal-bearing group of rocks may have thinned out before reaching the area, so that although the rocks above and below this particular group are found to underlie the area, and normally this particular group should also, yet under the circumstances, if this is the only coal-bearing group in the region that might underlie the area, it is classified as non-coal land.

2. Detailed study of the dip and lay of the rocks may show that the coal-bearing group lies deeper than the limiting depth imposed by the departmental regulations governing the classification of coal land, and the area must, therefore, be classified as non-coal land.

3. Detailed study may show that the area is underlain by a coal-bearing group of rocks within minable depth, but the coal is too low in grade to be worked, or it may be found that the coal occurs only in local pockets, none of which are thought to extend under the area involved.

Where, as is the case in many parts of the western coal fields, more than one group of coal-bearing rocks exists in any area, it must be found that the facts above stated are true of each group before the area can be classified as non-coal land.

On the other hand, if, although there is no coal outcropping within many miles of a given tract of land, it appears to be true that the tract is underlain within workable depth by a group of rocks known to contain coal beds of such character, thickness, and extent as to make it highly probable that they underlie the tract within workable depth and are there of workable thickness and quality, the tract is classified as coal land.

When such a tract of coal land is valued the attempt is made to take into consideration all the data bearing on the problem, possibly data covering half the State, or more, including usually data on every coal bed in every coal-bearing group of rocks of that field, to ascertain as nearly as possible how many groups of coal-bearing rocks underlie the tract, how many beds are of workable thickness, the thickness, chemical and physical character, depth, pitch, and any other factors affecting the workability and value of the coals, and then to make all due allowance for depth, uncertainty, distance from outcrop, etc., according to fixed schedules and regulations.

It must be admitted that the data gathered for many tracts are very meagre, and a large element of uncertainty enters into the final result, but it is believed that in the vast majority of cases the allowance for uncertainty is so large that additional data, even though they show less coal than might have been expected, will, by diminishing the factor of uncertainty, tend to raise the price rather than reduce it, for, as a rule, where the uncertainty is large only the minimum price is put on the land, and unless evidence such as that obtained by deep drilling or new prospecting shall demonstrate beyond question that the supposed beds of coal are absent or too thin or too poor to work, the classification will not be changed.

The evidence obtained by the United States Geological Survey consists of observed outcrops and measured sections, properly located and described on the spot, and analyses made in the Government laboratories from coal samples collected in a definite, prescribed way, supplemented when necessary by such second-hand data as appear to be accurate and reliable, and to be in accord with the personal observations of the field men.

EDITORIAL COMMENT.

At the annual dinner of the Dominion Marine Association, held last week in Ottawa, the Minister of Railways made an announcement concerning the new Welland Canal which shows that the Government and Mr. J. L. Weller, the engineer-in-charge of the design of the new work, are thoroughly alive to the necessity of providing for the future of the shipping interests of the Great Lakes. He stated that the lock-gates on the new Canal would be thirty feet in depth, although the depth of the Canal itself would be only twenty-four and a half feet for the present. When the locks at the Sault on both sides of the river are deepened to thirty feet, as they eventually will, it will be a simple matter to provide this depth on the Welland Canal by dredging.

SAULT STE. MARIE DRYDOCK.

Substantial interests are backing the enterprise of the Sault Ste. Marie Drydock and Shipbuilding Company, Limited, particulars of which appeared in The Monetary Times last week. The shareholders in the company consist of the estate of the late Mr. W. H. Plummer, Messrs. J. O'Brien, J. J. McFadden, J. O'Boyle and D. P. O'Boyle, all of whom are well known throughout Ontario; Sir Alexandre LaCoste, Messrs. Ernest Marceau and F. H. Clergue, of Montreal; A. Simpson, of Ottawa, and other Canadian interests. Among other strong financial European interests are Mr. Robert E. Pauwells, of Brussels, Belgium; Mr. William Brice, of London, England; Dr. Charles Casoretty, of Paris, France; and Messrs Pethick Brothers, Limited, of Plymouth and London, England.

RAILWAY HEADLIGHTS.

A review of the requirements for locomotive headlights by G. H. Stickney, is given in the January issue of the Lighting Journal, from which the following is taken:

In connection with the recent developments in drawn wire filament tungsten lamps, the writer has been led to look up the locomotive headlights as a possible application. It is the general practice to utilize for this purpose flame oil lamps equipped with parabolic reflectors so as to concentrate the light into a beam, although within the past few years, electric arcs have been substituted for the oil flames in some sections of the country.

In considering the application of tungsten filament lamps, the first question which arises is what intensity of beam is desired. Investigation shows that there is a wide variation of opinion among railroad men in regard to this point. Some insist that the headlight should be very powerful so as to illuminate a long distance ahead of the locomotive, while others object seriously to a powerful beam and demand that the headlight be made simply a marker. Analysis seems to show that the demand for the powerful headlight runs strongest on railroads which have a considerable amount of single track, while the other extreme reflects the opinion of such railroads as have two to four tracks and extensive block signal systems. And this appears to be logical. On the single track road the most dreaded accident is the head-on collision, and the powerful headlight is unquestionably an important means of last resort in preventing such accidents. On the double track roads the danger of head-on collisions is minimized, while complaint is frequently made that the headlight of an approaching locomotive momentarily blinds the engineer and may prevent his seeing properly. The further objection has been raised of the interference due to the reflection of light from signal glasses or rondels.

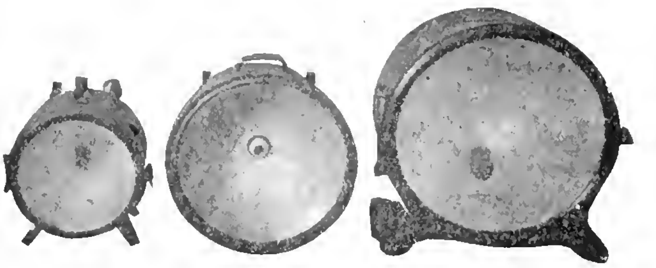

Fig. 1.—Types of Railway Headlights.

A thorough test was carried on by Profs. Harding and Topping, of Purdue University, in 1910, and their report, which may be found in the Transactions of the American Institute of Electrical Engineers, indicated in favor of a headlight of intermediate power; that is, one which would avoid the glaring and reflection effects of the powerful arc headlights and yet furnish a much stronger beam than the ordinary low intensity oil headlights.

There is, however, another phase of this question: namely, the legislative requirement. In many of the states laws have been passed regulating the headlights to be used on locomotives. Inquiry was made into the requirements of various states, and the following collation, prepared by Mr. L. C. Porter, gives a general idea of the requirements.

The States of New Jersey, New York, Connecticut, Minnesota, New Mexico, North Dakota, Virginia, Wyoming, Iowa, Massachusetts, Pennsylvania, Rhode Island, Vermont, Nevada, New Hampshire, Michigan, West Virginia, Nebraska, Missouri, and Delaware advise that they have no law covering this subject.

Colorado and Kentucky have had a bill requiring [illegible] of "1,500 unreflected candlepower" headlights introduced, but the bill was defeated.

Illinois had a bill introduced and defeated requiring each locomotive to carry a headlight of sufficient candlepower to enable the engineer to distinguish a human form at a distance of 800 feet.

Arizona has a bill pending requiring the use of a high candlepower headlight this bill calling for "1,500 unreflected candlepower" on all locomotives except switch engines.

North Carolina requires a locomotive headlight of "1,500 unreflected candlepower" on all locomotives, with the exception of switch engines, on roads having 100 miles or more of track within the State.

Washington requires that each locomotive be equipped with an electric headlight of approved design and capacity.

Montana requires that each locomotive, with the exception of switch engines, be equipped with electric or other headlight of 1,500 candlepower when measured without a reflector.

Wisconsin requires that each locomotive be equipped with a headlight which will enable the engineer to see a man on a clear night at a distance of 800 feet.

Ohio requires that each locomotive, except switch engines, shall carry a headlight of such candlepower as to render plainly visible, at a distance of not less than 350 feet, whistling posts, land marks and other warning signs.

It is somewhat of a reflection upon the activity of illuminating engineers that in no case was the intensity of beam specified in beam candlepower or foot candles at some specified distance. It does not seem reasonable or good practice to require 1,500 unreflected candlepower, without any mention of the quality or condition of the reflector. While it might be presumed that an efficient parabolic reflector would be used, there seems to be no assurance that this would be done. The specification seems to favor one type of unit to the exclusion of others which may be more effective, as well as more economical and practical.

The requirement of sufficient intensity to pick up a man at 800 feet is the most logical and sensible of any of the specifications given. While this is somewhat indefinite and somewhat difficult of exact determination, it was probably the best requirement that could be drawn up with the information then available. As suggested, this specification could readily, by a series of tests, be interpreted in terms of foot candles at, say 200 or 400 feet, or beam candlepower measured at corresponding distances. These values are more readily reproducible than general specifications, which may depend upon local conditions, such as the color of the roadbed, color of background, color of clothes worn by the man, etc.

It is understood that this question is now under investigation by the Wisconsin Railroad Commission and others, and it is hoped that good results will soon be available.

The writer has not made any accurate measurements to determine the relation between intensity and seeing power. A western railroad, which has been conducting such experiments, reports that, with an equipment utilizing a 100 c.p. tungsten filament lamp* with the filament concentrated in a cylindrical space about ½ inch long and ⅜ inch diameter, they were able to pick up a man on the track at 1,000 feet, the locomotive being stationary, and at 800 feet with the locomotive running 30 miles per hour.

Measurements with a similar equipment gave a beam candlepower of 50,000, which is equivalent to .078 foot candles

*The lamp mentioned was made up especially for the experiment and is not standard or commercially available.

at 800 feet and .05 foot candles at 1,000 feet. The beam candlepower obtained in this case indicates the inadequacy of the specification calling for 1,500 unreflected candlepower, which does not ensure anywhere near as powerful a beam as is here produced from a lamp giving only about 100 unreflected candlepower.

A second question which arises and to which there has not, as yet, been a final answer, is the requirement of the shape and width of beam. Ordinarily a fairly narrow beam would seem to be desirable, since it not only makes it practicable to furnish a high intensity down the track, but also minimizes interference with signals or approaching trains on either side of the track. On the other hand, a wider beam would be more useful on curves.

Still a third question is that of the color of the light. Professor Harding's report intimated, to some extent that interference with colored signals was in some degree due to the color of the light, but it is in its relation to weather conditions that the color of the light would seem to be the most important consideration. The headlight question would be a comparatively simple one if fair weather only were to be considered, but the real test comes on the foggy or stormy night, when the mist or rain not only breaks up the beam, but reflects the light back into the eyes of the engineer, thus causing a haze which makes it more difficult to see distant objects, which, in themselves may be darkened and rendered less visible by being wet. That the most powerful light may be the worst under such conditions is quite conceivable; on the other hand, we know that a red or yellow light penetrates a fog more readily than the other colors, and hence not only delivers a larger proportion of the light where needed, but also decreases the likelihood of the haze or diffraction effect obstructing the vision of the engineer.

It may be well to consider briefly the theoretical and practical requirements of a headlight for railway purposes, at least from a qualitative standpoint, assuming that a reasonably powerful headlight is desirable.

As is well known, a perfect parabolic reflector, equipped with an absolute point source of light at its focal point, would reflect all the light incident upon its surface in a direction parallel to the axis, and hence form a beam which would retain its intensity for an indefinite distance, barring only atmospheric absorption. In the practical application of this principle, it is not possible to produce a true point source, so that the actual light incident upon each point of the reflector will, in all cases, come from several directions, at least within an appreciable angle, and, since the angles of reflection and incidence must be equal, it is evident that each point of the reflector will emit a cone of light, depending for its width upon the angle which the light source subtends with reference to that point of the reflector. It is also evident that, since at a distance from the reflector these cones will appear to blend, the beam of light from a parabolic reflector must be in the form of a cone and be dependent for its spread upon the relative area of the light source. It therefore appears that, where a powerful, narrow beam is desired, it is essential that the light source be made as small and brilliant as possible.

This condition is, of course, best met with the D.C. open carbon arc, which can be so arranged that a large percentage of the light from the positive crater is projected upon the reflecting surface. The carbon arc, however, is efficient and stable only in high power units. With the recent development of the drawn wire tungsten filament, it has become possible to make lamps in which the filament is concentrated into a very small space, and is strong enough to withstand reasonably hard treatment. The lamp possesses the further advantage of being free from mechanism to get out of adjustment or requiring maintenance care, does not smoke or destroy the reflecting surface, and produces a light of slightly yellowish tint, which is favorable for inclement weather conditions.

Incandescent headlights have proved very satisfactory for automobiles and are being used to some extent on interurban electric cars. It would seem that this application to railway service is principally a question of determining the requirements and adapting the automobile type of equipment to them.

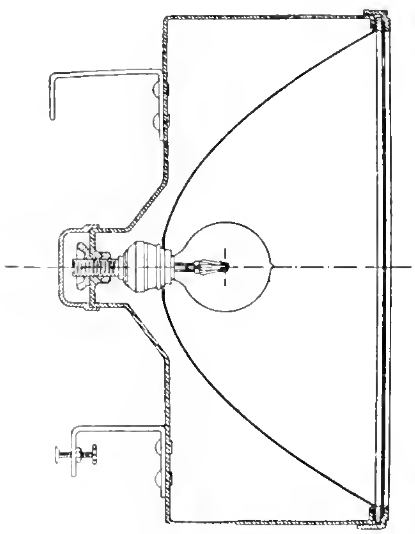

Fig. 2. Suggested Arrangement for Railway Headlight for Use With Mazda Lamp.

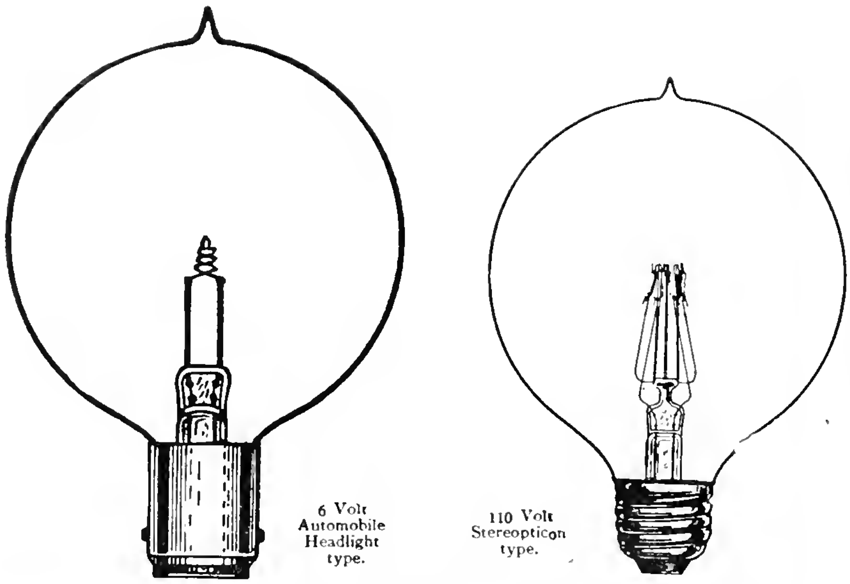

Fig. 3. Concentrated Tungsten Filament Lamps Suitable for Headlight.

Mr. F. H. Ward has resigned the position of vice-president of the Canadian Consolidated Rubber Company, but will remain a member of the executive committee and a director of the company. He will in future be associated with Mr. D. Lorne McGibbon

THE PIECEWORK OR UNIT SYSTEM OF HANDLING TIES AND TIMBERS.*

By W. W. Eldridge.†

The handling of ties and timbers on a "Piecework" or or "Unit" basis is, I believe, not universally practiced in the timber-treating industry. Some plants follow the practice to a greater or lesser extent under one system or another.

Our company has been using the piecework system of handling ties and timbers at both our plants for several years with what we consider the best of results, and my remarks will be confined to the efficient operation of a timber-preserving plant from a physical standpoint only.

A short time ago I asked my friend, Mr. Waterman, what he thought of the "piecework system," and he replied: "Piecework is the only thing for the timber-treating plant." This opinion is backed by thirty-odd years of practical experience in the handling of material, principally ties, piling and lumber, and men of all kinds, under both the "day work" and "piecework" system. I may be easier to satisfy or convince than some of you, but this recommendation is good enough for me. The proof of the pudding is in the eating, therefore, my only recommendation is that you taste it. If you like it you will eat more, if not you will leave it alone.

The question arises, "What is the object of piecework, and what are the advantages to be derived therefrom?"

The object of piecework is to get one dollar's worth of labor for one dollar, and to give one dollar for one dollar's worth of labor, or, in other words, to increase the efficiency in handling ties and timbers to the maximum so as to get the largest possible output at the least cost.

The advantages of the piecework system are numerous. In the first place, it reduces by approximately one-third the number of men required to do the work, and hence makes a corresponding decrease in the amount of supervision needed.

It enables you to get the "cream" of the laborers to do your work. There is no place for the "drone" in the piecework system, as he will be pushed aside and eventually crowded out.

It systematizes the work and assists materially in the accounting, figuring costs, etc.

It places each individual workman in business for himself, and enables him to secure pay for what he does. Being paid for what he does, it is natural for him to combine mental ability with physical strength in order to accomplish all possible.

Knowing that he is getting paid for what he does, and that in proportion as his efforts are increased his earnings are increased, he is able to make better wages than his fellow-workmen in other lines of business on a day rate system, hence he is satisfied and contented with his job at all times, and when the "shortage of labor" problem arises you will find your men still at the helm, while other industries on a day rate basis are suffering for lack of laborers, which means loss of business and decrease of efficiency and earning power. This condition brings out another important point, and that is, always treat your men in such a way and improve conditions to such an extent that the glitter of gold, so to speak, will not entice them to abandon the best of working conditions and a sure thing for an experiment. You will always find a few who are prone to become dissatisfied and wander away in search of something better, but my experience has been that within a short time they will drift back, sadder but wiser for their experience. Last, but not least, it promotes efficiency.

The installation of the "piecework system" is no small task. A great deal of tact and good judgment must be exercised, and unless it is established on good business principles it will be a failure rather than a success. There are a good many things to be taken into consideration along this line.

First, be open and above board with your men in everything you do in connection with their work, as it is of the utmost importance that the men fully understand what you expect of them, and what they can expect of you in return. You must have confidence in your men and they in you to obtain the best results to all concerned. Every detail should be fully explained to them. The existence of doubt would be disastrous, and might be likened unto the little Toredo, which enters the piling unseen and slowly but persistently destroys life and tissue until nothing but the shell is left and the piling fails. Metaphorically speaking, you should so thoroughly impregnate the minds of your men with the antiseptic "piecework" that there would be no chance for the little Toredo to gain entrance, to say nothing of existing, in your piling "the piecework system."

Second. Treat your laborers as men, and be fair and square with them at all times. Be ready and willing to counsel with them and explain any points that are not quite clear to them. My experience has been that there is a common feeling among men that in order to exist under the piecework system they must exert themselves unduly. This impression is erroneous, and you should disabuse their minds of the same. The man who starts out in the morning on a run to perform his work, regardless of method, does not accomplish the desired result, for the reason that he has set a pace that is not in keping with his physical ability, and before the day is half done he is exhausted and compelled to quit. What is the result? The man is dissatisfied because he is disappointed with the results of his efforts, and he immediately condemns the system when in fact he should condemn his own lack of good judgment. In no case should a man be permitted to set such a pace, but rather strike a good even gait that he can maintain throughout the day, and by combining method and system he will be more than satisfied with the result.

When you have done all this you have gained their confidence, and when you have won their confidence you have won a battle, gentlemen, that means much to you and to your men. The spirit of indifference vanishes, and the spirit of co-operation and mutual interest is enthroned in its stead. I doubt if any of us could place a monetary value on the loss incurred by the indifference, carelessness and wastefulness which is bound to occur when all men are classed as physically and mentally equal and all paid the same stipulated scale of wages for the same class of labor. If you are a careful observer and have ever taken the time to watch a gang of men working on a day-rate basis, they having no knowledge of your presence, what did you observe? This is what you saw. A gang of men organized to do a certain piece of work without regard to the number of men, their comparative size, strength or ambition. You saw one or two, or possibly three of the men performing, at least a part of the time, all of the work that was being done, while the rest of the gang was looking on. You also saw that their efforts were absolutely devoid of system. You will naturally ask, "where is the foreman?" in most cases he is everywhere but where he should be, but in either case you will invariably find that the foreman has imbibed the same spirit exhibited by the men under him, and the only purpose he serves is to point out to the men what he wants and leaves them to work out their own salvation in any way they see fit, regardless of time, ex-

* Abstract of paper delivered before the American Wood Preservers' Association.

† General Piecework Inspector (State Department), Chicago, Burlington & Quincy Railroad.

pense or efficiency. Only the other day I was going along the street when I saw a gang of twelve men handling some stone cornice work. For ten minutes eleven of these men did nothing, while the other one was trying to saw a one-inch board in two with a hammer. The board was finally cut, and then six of them picked up a piece of stone and loaded it on the wagon, and still there were six men looking on and drawing wages for expert advice or statuary effect, I presume. I could see no other reason for keeping them there.

What do we get out of this object lesson?

Woeful lack of efficiency and improper organization.

The foreman should have been released for permitting such a condition to exist under his supervision.

We find twelve men drawing wages for a six-man job. Undoubtedly the prevailing spirit was to let the fellow who was willing do the work.

With the piecework system it is different. Every man or gang of men secure a job on their merits, the goal is pointed out to them, and immediately they enter the race with a determination to reach that goal. Some few fall by the wayside, either for lack of strength, ambition or ability, but the majority of them win the race under proper supervision, and are giving you one dollar's worth of labor for your dollar. Under the day-rate system there is no incentive for the man to do other than plod along from morn till night, day in and day out, doing as little as he can and hold his job. You might drive him, but he is continually grouchy and dissatisfied and you do not get results. How much nicer it is to have a man jump into his work with a will of his own accord, and how much greater the results to all concerned. Under the day work system his highest ambition is to see that he does no more than his fellow-workman. The piecework system sets him to thinking, and figuring out ways and means of accomplishing all he can in the best way he can to promote his and his employer's interests. He knows that he is in a sense an essential part of your organization and that his services are appreciated.

For example: We have at one of our plants a gang of nine or ten men loading trams with ties for treatment. In this gang is one man who will average sixteen trams per day, another who will average fourteen, while the poorest man in the gang averages eight to nine trams. How long would the sixteen-tram man continue to load sixteen trams if his compensation for the day's work was no more than that of the eight-tram man? Why is this man able to load sixteen trams and his co-worker only eight or nine? In this case it is partly due to his superior strength, but in a great measure it is due to his superior ability in other ways to handle ties. He has studied out all the short cuts and knows just how to pick up a tie, how to shoulder it, and how to land it on the tram where it will require the least possible shifting to properly load the tram. To what degree do men become efficient? To illustrate this I will give you the benefit of one or two of my own personal experiences. On this occasion we received an extra heavy consignment of ties in cars that were badly needed for commercial loading. The regular force was not large enough to release these cars as quickly as desired by the management, consequently they diverted two or three extra gangs to help out. The regular men were working piecework at ⅝c. to ¾c. per tie, and averaged from 25c. to 30c. per hour. The extra gang were working for $2.00 per day, and unloaded their portion at a cost of .03½c. to .04½c. per tie. Why this cost? Because the men were working for a stipulated rate of wages, and because they had absolutely no knowledge of how to handle a tie, and furthermore were physically unable to cope with the regular men, due in a great measure to their habits of living. I will leave it to you, gentlemen, to figure out which was the best paying proposition to either the company or the men

The installation of piecework would, of a necessity, need to be worked out to fit conditions peculiar to each individual plant, hence it would be useless for me to attempt to tell you what rates should be applied, but there are several important underlying principles that should apply to all.

First. The selection of competent supervision, or foremen. A man to be a good foreman must be wide awake and energetic at all times. He should be familiar with every detail of the work assigned to him, as also the most practical way to handle ties and timbers so that he can impart it to his men. He should have a knowledge of handling men and be on the ground all the time. He should not be a slave driver, but should be firm and diplomatic in all his relations with his men. These men should understand that his word is law, but if for any reason they deem his demands unreasonable they should be at liberty to put the case up to the general foreman or other higher authority for final decision. In my opinion the superintendent or manager personally should make the final decision, if necessary to carry it that far.

Second. Care should be exercised in perfecting your organization to place your men to the best advantage, and to see that there are no more men in the gang than needed, and yet enough to handle the work without delay to other parts of the organization. You would not hitch a draft horse and a donkey to the same wagon and expect to get efficiency. This is a feature that should be considered in the personnel of your organization.

Third. Schedules should be made to cover each and every operation. These schedules may be based on any of the following units, depending entirely upon your own views and the existing conditions.

Ties—Per tie, or per team loaded.

Lumber, switch ties and crossing plank—Per 1,000 feet boardmeasure.

Piling—Per pile, or per lineal foot.

We have found the following a very good plan:—

Unloading and storing ties on ground—Per tie.

Loading trams for treatment—Per tram.

Unloading treated from trams to cars—Per tram.

Unloading treated from trams to ground—Per tram.

Piling, when handled with derrick—Per pile.

Piling, when handled by hand—Per lineal foot.

Paving blocks—Per square yard.

Lumber—Per 1,000 feet boardmeasure in all cases.

Fourth. In wording your schedules particular attention should be given to the phraseology to see that it is clear, concise and easy to understand, so there will be no chance for any dispute to creep in under the guise of a technicality, and last, but not least, cover all the work which you expect the men to perform under any schedule.

In handling ties and lumber of all kinds a distinction should be made between hard and soft wood as follows:—

Oak or hardwood.

Pine or softwood.

This for the reason that pine or fir weighs approximately three pounds per foot, while oak weighs five pounds per foot. You would not expect any man to handle 5,000 pounds for the same price as 3,000 pounds.

A competent man should be selected to make the schedules and establish the rates of pay. In order to get the best results he should have a knowledge of handling men and material. He should be competent to recommend practical changes or improvement of conditions, tools or other devices that will facilitate the handling of the ties or timbers. Oft-times a dollar judiciously spent to improve conditions means many in return. In establishing prices it is important that all the facts and figures bearing on the operation be accumulated in order that prices may be established on an intelligent basis. To accomplish this the party getting the in-

formation should be on the ground personally, watch the operation from start to finish, and make notes as to number of men, kind of material handled, how handled, time consumed by each man, degree of efficiency, or anything else that would have an important bearing on the wording of the schedule or the base rate. Prices should be based on three things: the authorized hourly rate, degree of efficiency obtained under the day rate system, and the conditions and tools furnished.

All prices should be made on a basis that is fair to the employer and the employee. Once a price is established it should never be changed unless there is a change in conditions. Suitable blanks should be provided for keeping the time and checking material in and out. These will be turned in to the timekeeper daily to figure up and enter on the pay roll.

In establishing piecework a good plan is to start in with some one gang. Advise them daily of their earnings and arrange it so that the rest of the men working on a day rate will know what this gang is earning. They will immediately begin to get interested and ask for the piecework system, and in a short time your entire force is working on the piecework basis. There will perhaps be days when, due to some peculiar unforseen condition or nature of the material, the men will fall below their former day rate, while there will be other days when they will do exceptionally well, hence only the average for the month would be a fair comparison.

Foremen should be on a monthly basis, the rates to be fixed according to your own ideas. In no case should a foreman have supervision over more than twelve men, and eight or nine men is better, in my opinion, when handling ties or lumber by hand. The duties of the foreman are to instruct his men what to do, give them the benefit of his experience in handling material, keep them supplied with work at all times, see that it is properly done, and keep track of their time and material handled, checking same personally in all cases.

When unloading ties to season, also loading trams for treatment, each man works as an individual. When handling treated ties the men generally work in pairs or gangs of three, each man getting an equal proportion of the earnings of the gang. If a man is taken out of the gang during the day and another put in his place, the foreman should take proper record so that the earnings can be properly apportioned. With us when unloading ties to season no effort is made to sort them. The sorting as to kind of wood and grade is done when loading them to trams. When unloading switch ties by hand we find four men to the gang the best, and handling switch ties, piling and lumber with a locomotive crane three men in addition to the engineer. In all cases I would advocate the same rate from start to finish of an operation, unless some unusual condition arises. The man gets the same for the last tie as for the first.

There is a maximum to all things when efficiency is considered. In storing ties to season, piling them eight to one, the maximum height of the pile should be sixteen to eighteen feet. Treated ties when piled on the ground should be in solid square piles eight to ten feet high.

It has been said that ties and timbers cannot be properly piled under the piecework system. In this connection I would invite your attention to some photo views which I have taken at our Galesburg plant showing what we accomplish under this system. These photos are representative views of our entire yard, not a pile here and there. I would call your particular attention to the symmetrical piles, both from a side and end view, as also the alignment of the piles. Look them over and decide for yourself whether or not ties and timbers can be properly piled under this system.

Someone has said that the efficiency of a timber-treating plant should be based on the number of retort hours worked out of the total possible retort hours. In obtaining efficiency in plant operation the fact must not be lost sight of that good and effective treatment is the first or primary object, and at the same time your supervision, your organization, and your system of physical handling must be the best possible. This is what we claim to have under the "piecework system." During the year 1912 at our Galesburg plant we obtained on the above basis 98¾ per cent. efficiency, or, in other words, each of the three retorts were in actual operation 98¾ per cent. of the time. This means that out of a total of 7,488 possible retort hours for each retort they were operated 7,394.4 hours, holidays excluded.

Efficiency is a watchword, and the day is now at hand when the railroads, the corporations and the business man in all lines expects and demands efficiency. This demand is growing every day, each year we are expected to do better than we did the previous year until we have reached the limit, and unless you and I, or whoever is held responsible, get in "the efficiency band wagon," we are going to wake up some day and find someone else occupying our seat.

PRESERVATION OF LUMBER FOR CAR CONSTRUCTION.*

By J. H. Waterman.†

I have been requested by your committee on programme to write a paper on the above subject. I have compiled a few facts for you, but before I give you the facts I want to say that my observation leads me to make the statement that treating lumber with creosote for car construction will be necessarily limited, on account of the fact that it is impossible to paint timber, or rather impractical, after it has been creosoted. Most roads in this country have a standard color for their cars, and they would not want to change that color to black in order to please the wood preservers of this country. If any road should desire to change their stock cars to a standard black, then the creosoted timber would be the ideal, for they would be permanently painted, providing the timber was framed before it was treated, and as they are used for taking stock to the market, which means the grave for the stock, why not advocate painting all the stock cars in this country black. It would be a good color, if it did remind you of a funeral train as it went by.

So far we have treated only car sills and car decking.

Fir Car Sills.—To date we have treated a total of twenty-three runs.

We succeeded in getting an average absorption of 11.41 lbs. per cubic foot.

Board feet treated, 326,204.
Average steam pressure, 15 pounds.
Average time steam, 2 hours 23 minutes.
Average initial vacuum, 23 inches.
Average initial vacuum held, 1 hour 37 minutes.
Average solution pressure, 175 pounds.
Average solution pressure held, 17 hours 26 minutes.
Average final vacuum, 20 inches.
Average time final vacuum, 1 hour.

Fir Car Decking.—To date we have treated a total of thirty-nine runs.

* Abstract of paper delivered before the American Wood Preservers' Association.

† Supt. Timber Preservation, C., B. & Q. R.R. Co.

We succeeded in getting an average absorption of 14.33 lbs. per cubic foot.

Board feet treated, 1,013,472.

Average steam, 15 pounds.

Average time steam, 57 minutes.

Average initial vacuum, 24 inches.

Average initial vacuum held, 1 hour 6 minutes.

Average solution pressure, 175 pounds.

Average solution pressure held, 13 hours 10 minutes.

Average final vacuum, 21 inches.

Average time final vacuum, 1 hour.

The Fir Car Sills.—In the sap wood we got a thorough penetration; in the hardwood not to exceed one inch all around.

In the car decking, when it was dry, it was thoroughly penetrated with creosote. I presume you all understand that car decking is 1¾ inches thick.

Our people feel that it is not only practical, but that it pays, to treat the car sills and car decking for stock cars. You all realize that it would be impractical to treat car decking for box cars on account of the odor. They could not be used for flour and many other lines of merchandise, which would absorb at least the odor from the wood if treated with creosote. We never can look for a very broad field to operate in so far as treating car lumber goes. However, I believe it is practical to treat car decking for stock cars and flat cars. For stock cars it also acts as a disinfectant, and from that point it would be not only practical but, I believe, effective, and the roads that are using lumber for car sills, there is no question but what it would lengthen the life very materially. How much I am not able to say, for we have only practiced treating car sills and car decking for about one year.

All of our new stock cars now that we build with wooden sills we treat the sills and all of them we treat the decking.

I would recommend that the president appoint a standing committee to go into carefully, not only the treating of car sills, but the treating of any and all timber which would be practical, and by that means the field for treating timber will be broadened and strengthened, and the committee should have power to make recommendations, and we, as the American Wood Preservers' Association, should stamp our approval or disapproval on what they recommend. And, gentlemen, I believe it would have weight in the commercial world, and what are we here for if we do not further our own interests and conserve the forests of our country by getting the longest possible life out of all wood that is used.

THE REQUIREMENTS FOR SUCCESSFUL TIMBER TREATMENT.*

By Hermann von Schrenk.

Treated timber has been used in the United States for a sufficient number of years so that we are beginning to obtain some results. As is the case in every other industry, some failures are becoming evident in various parts of the country. During the last year I have spent a good deal of time investigating the reasons for failures of pieces of so-called treated timber. I say so-called treated timber advisedly. In discussing the causes for failure of the cases referred to with a number of persons interested in wood preserving, it was suggested that I say a few words about the general subject of successful timber treatment to the members of this association. I do this with the feeling that there is probably no subject in which we are more vitally interested than to see to it that the results of our labors give satisfactory returns to everybody concerned.

Timber treatment has grown so rapidly in the United States that the amount of material actually treated every year is ten times what it was seven or eight years ago, and the number of men engaged in the industry has correspondingly increased. As the use of treated wood has increased, inevitably some conditions have arisen which I believe it is well for us to consider. In the early days of timber treatment there was a good deal of experimenting as to methods, and, for that matter, there is still some experimenting, but, as the result of some twenty years' experience, some facts are sufficiently well known at the present time to all of us, and these facts have become more or less axiomatic. Briefly stated, in order to get good results from treated timber the following points must be observed:

1. Only perfectly sound timber should be treated.

2. In order to obtain the best results, properly seasoned material should be used.

3. A good preservative is essential to long life.

4. Proper injection as to quantity and penetration is essential.

5. Proper subsequent handling of the timber is essential.

In my investigations I have found that the premature failures of so-called treated timber were almost without exception due to the non-observance of one or more of the above principles. I am perfectly sure that in the early days a good deal of timber was treated which was sap rotten. It was not realized ten years ago, as it is to-day, that timber may be very badly decayed in the interior and yet show absolutely no evidence on the outside. With the best intentions, therefore, many sticks of wood were doubtless treated which we would unhesitatingly throw out to-day. Many of the failures were, however, due to the fact that timber was treated because of certain contract requirements and in spite of a better knowledge of the person responsible for the actual treatment. The lessons to be drawn from failures are very obvious, and I believe we should take cognizance of them, particularly in view of more thorough knowledge of all the factors surrounding the operations which make for successful treatment.

While there is no doubt very general agreement among the men engaged in the timber-preserving industry as to the fundamental conditions enumerated above, we all know that frequently, under stress of business circumstances, they are not always adhered to. The consumer frequently makes demands which cannot be fulfilled, and if they are they are bound to result in speedy and ultimate failure.

The inspection of material before treatment should be made with greater care. I believe that every treating company should be empowered to refuse to treat material which they know to be defective. In other words, I do not think that anyone is warranted, under any circumstances, to treat material which he knows to be unfit because of various defects. A defective stick was never improved by any kind of treatment.

The same holds true for improperly seasoned material. The excuse is frequently given, in demanding treatment of absolutely green material, that emergencies have arisen which necessitate such treatment, or some similar explanation is given. Unfortunately, with the increased use of timber in its various forms, the tendency to require and do such rush work seems to me to be increasing. It is frequently inconvenient to wait six or eight months, or more, to properly season material; besides, it costs considerable for interest charges.

That which has been said for the inspection of the material before treatment holds equally for the preservative used and the manner of treatment. How much service do you suppose will be obtained by treating green red oak ties with two gallons of creosote oil by the full-cell process? We all

* Abstract of paper delivered before the American Wood Preservers' Association.

know that the penetration of timber so treated is insignificant and that internal sap rot is bound to occur in comparatively short periods of time.

I may be treading on delicate ground when I refer to the relation which should exist between a treating company and its customer. I have no hesitation, however, in saying that I believe it to be the duty of the man who knows how timber should be treated (because that is his business) to protest vigorously against any requirements which necessitate his treating a customer's material in a manner which he knows to be wrong. I wish to protest against the tendency which requires the actual treating operation to be conducted in accordance with any demands which may be made by the customer, because not only does this give disappointing results so far as any particular piece of work is concerned, but also because it reacts on the company doing the work and on the industry as a whole. The people as a whole are apt to forget that when the piece of so-called treated material fails, that that particular piece of material was treated under unusual conditions, no matter how much these conditions may have been justified at the time. I wish to protest against the "necessity" tendency to do rush work. We might as well face the problem now and say that successful treatment of timber can only be accomplished by observing certain laws, and that when one or more of these laws are broken, the consequences will be swift and certain. If I had the opportunity I could demonstrate the truth of this statement to anyone interested, and all I would have to do would be to show him some choice samples of so-called treated timber, which I have in my possession, which failed after three or four years' service, and explain why it failed, and then point to work well done, with twenty to thirty years' service behind it.

I have referred in this brief manner to what appears to me a very important situation affecting the timber-preserving industry at this time, and as one interested in the timber-preserving industry, and anxious to see timber last, I speak also as one anxious to see those engaged in this industry put into a position to carry out its basic principles. I know that there are difficulties which both the consumer and the timber-preserving company have to meet, and, as in all other affairs, that there are emergencies which will warrant doing exceptional things. I know also, however, that frequently requirements are made in the best of faith which it is hard to object to. I believe it would be perfectly proper for this association, standing as it does, for all that is best in the wood-preserving industry, to give expression to some of the sentiments herein expressed. I would favor the passage of some resolution emphasizing the necessity for a careful observance of the principles referred to. I am sure that a strong statement coming from this representative organization would be of the greatest service in giving a proper appreciation of what the wood-preserving industry as a whole stands for.

NEW STEAMER ORDERED.

The Collingwood Shipbuilding Company has been awarded a contract for a combined passenger and freight steamer by the Pelee and Lake Erie Navigation Company, which operates between Pelee Island and the mainland ports including Rondeau. The new steamer will be constructed of steel and will be 145 feet long with 24 feet beam and a depth of 18 feet 3 inches. It will be a day boat and will be fitted up specially for the route on which she will ply. The motive power will consist of triple expansion engines, 12½, 21, 34 inches with a stroke of 21 inches. This will be supplied with steam by one Scotch boiler 12 feet 6 inches in diameter and 10 feet 6 inches in length. The steamer will develop a speed of thirteen miles per hour. The contract calls for delivery in July next.

TORONTO RAILWAY COMPANY.

The gratification of a shareholder who was present at the annual meeting of the Toronto Railway Company this week, at the excellent financial statement presented by the directorate, was apparently disturbed by prospects of civic competition. Mr. Fleming, the general manager, however, quieted those fears, merely pointing out the heavy loss at which the short existing civic lines were being run. Every street railway is trailed by an army of critics. Mr. Fleming told his shareholders, and incidentally the army, that the Toronto system is one of the best on the continent, and we think that fair-minded critics will agree with the statement.

The gross earnings last year amounted to $5,448,050. Deducting therefrom charges of $2,866,550 for operating, maintenance, etc., the net earnings were $2,581,500. Several substantial payments were made from that sum, the heaviest being to the city and amounting to $942,048, while $879,595 represented dividends to the shareholders. Bond interest, etc., absorbed $190,992. The payments to the city were greater by $119,815 or 14.6 per cent. than in the previous year.

The progress of the company in recent years is shown in the following table:—

	1902.	1908.	1912.
Gross income	$1,834,908	$3,610,272	$5,448,050
Operating, maintenance.	1,015,361	1,889,046	2,866,550
Net earnings	819,547	1,721,226	2,581,500
Passengers carried	44,437,678	89,139,571	135,786,573
Per cent. of charges to passenger earnings .	55.3%	52.9%	58.4%

The Toronto and York Radial Railway Company report that their earnings continue to show satisfactory increases, the gross earnings amounting to $492,922, compared with $449,059 for the previous year—an increase of 9.76 per cent.

OTTAWA ELECTRIC RAILWAY.

The shareholders of the Ottawa Electric Railway Company have every reason to be pleased with results of operations for the year ended December 31st, 1912. The gross earnings were $934,397, an increase of $93,717 over the previous year. The net earnings were $400,059. Out of that sum, four quarterly dividends of 3 per cent. and a bonus of 3 per cent. were paid, being a distribution to shareholders of $255,947. The gratification of the shareholders was further strengthened by the prediction of Mr. T. Ahearn, the president, that the prospects for the coming year are of the brightest character.

The growth of the company in the past few years is clearly shown in the following table:—

	1893.	1903.	1912.
Gross receipts	$110,071	$348,888	$934,397
Total expenses	70,221	254,346	578,540
Net income	39,850	94,541	355,856
Passengers carried	2,394,504	7,911,718	21,815,798
Per cent. of operating expenses to receipts		61 4-5%	57 1-5%

After the payment of dividends and bonus last year, the substantial sum of $69,000 was placed at the credit of contingent account to be applied to the reduction of track renewal, car equipment and other accounts. Interest on bonds and loans absorbed $21,303; mileage payments, $13,435, and taxes, $9,463. There remained a sum of $30,908 for transference to credit of profit and loss account. The balance at credit of that account is now $138,264 and at the credit of rest account $200,000. Several important improvements were made to the company's system last year, by which the earning capacity and facilities for handling the increasing traffic will be greatly augmented.

NOTES ON STAKING OUT TRACK CONNECTIONS.

The solution of maintenance engineering problems in railway work is well treated in an article published in the January 24, 1913, issue of the Railway Age Gazette. This article is written by W. H. Wilms, and is here given in full.

The ordinary field book is of slight value to the engineer engaged in maintenance work in the solution of track problems. None of the problems presented in such books have been solved with a view to practical application. Following the methods outlined in these books, it is not uncommon, for instance, to see new sidings staked with the initial curve tangent to the centre of the track from which the turnout leads, although a little study will show that the curve is not necessarily tangent to the frog, and unless it is tangent, an elbow must be thrown in the curve, or a piece of tangent introduced, depending on whether the curve beyond the frog is of less or greater degree than the curve back of the frog. In either case, the siding presents a bad appearance and in case of an extremely sharp curve and close quarters, the engineer would probably find the siding could not be operated until relocated. The only field book that has attempted to treat track problems with a view to practical application by means of a so-called "reference curve" makes such problems really more complicated than they are. In the following notes only such problems as commonly occur in practice are given, leaving it to the ingenuity of the engineer to modify these methods to meet his particular requirements in more complicated cases. While no claim to originality is made in the solution of these problems, it is believed a number of them will be new to not a few engineers.

Switch Leads.—From both the operating and maintenance standpoints the installation of turnouts leading from curves is to be avoided whenever practicable. When the installation of a turnout on the outside of a curve is unavoidable, the switch leads should be made straight wherever it is possible

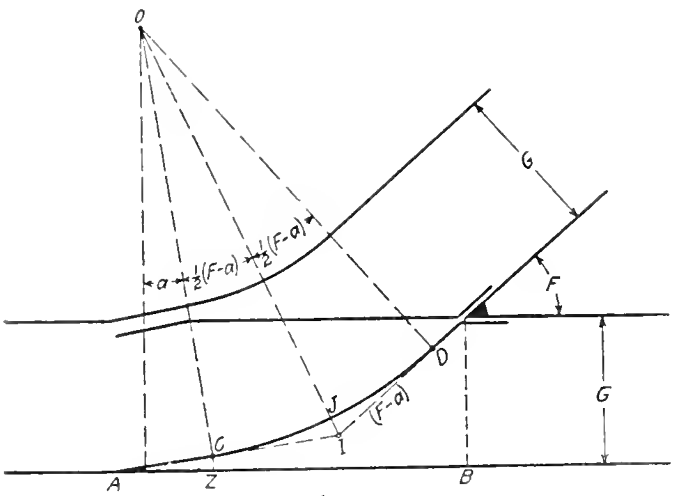

Fig. 1.

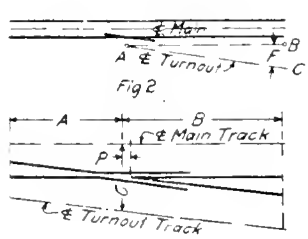
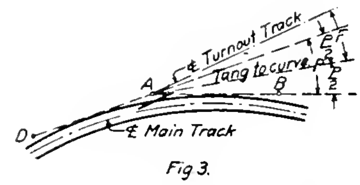
to do so, as the benefits in safer operation and decreased maintenance of the switch by using straight leads are very pronounced. Often a slight change of alinement or the substitution of a different size frog will readily effect this.

Of equal importance is the reduction to a minimum of the curvature in the leads of a turnout on the inside of a curve. This also can often be effected by slight changes in alinement and the substitution of a higher frog number.

Also, for similar reasons, the alinement of the turnout track immediately beyond the frog is of importance. Where a curve is necessary it should, if possible, be of the same degree as the curvature in the lead; otherwise there results the objectionable feature of a change in curvature in a very bad place, which not only looks bad but is apt to be a constant source of trouble in operation and maintenance. This is especially true where the curvature is sharp and connections close.

In order to obtain a solution to such problems as the above where the alinement of the switch lead is taken into consideration, it is quite necessary to know the actual length and degree of curve of the leads of the road's standard turnouts from straight track. Knowing the length of switch rail,





No	Angle	A	B	C	D	p	Lead

Fig. 4.

spread at heel of switch and length of frog from theoretical point to toe, the length and curvature of the lead are readily obtained from the following formulas:

(From Manual of Am. Ry. Eng. Assoc.).

F = Frog angle
W = Length of wing rail of frog
S = Length of switch rail
H = Heel distance of frog
G = Gauge of track
R = Radius of centre line of lead curve
a = Switch angle

$$\text{Lead dis. AB (Fig. 1)} = (S - W)\frac{\sin \frac{1}{2}(F - a)}{\sin \frac{1}{2}(F + a)} + G \times \cot \tfrac{1}{2}(F + a)$$

$$\text{Radius of lead curve} = \frac{G - H - W \times \sin F}{\cos a - \cos F} - \frac{G}{2}$$

Having once computed this data from the road's standard frog numbers, the engineer should place it in his field book for future reference.

Significance of Stakes.—Due to the fact that many track foremen and supervisors have to work to stakes set by many different engineers, some of whom make it a practice to set stakes indicating the location of a frog on the rail line at the theoretical point and others who set such stakes on the centre line of track opposite the actual point, costly mistakes sometimes result. To avoid such trouble, it is a good plan to have some definite system of marking and setting stakes, and after the tracks have been staked out to go over the layout with the track foreman and explain to him the significance of the stakes, so that when track laying begins there will be no chance for mistake or confusion. In most cases it is unnecessary to take into consideration the difference between the theoretical and actual points in the location of a frog. There are a few cases, however, where a failure to observe this difference would result seriously. For example, in the location of the frogs of a No. 10 crossover between parallel straight tracks, 13 ft. centre to centre, where the track is straight between frogs, the distance from theoretical to actual point of a No. 10 frog with a ½-in. point is 5 in. Now, if stakes are set for theoretical points and the foreman sets the actual point of frogs to these stakes—a thing he is very likely to do unless the significance of the stakes has been explained

to him—there will result a total error in the position of the two frogs of 10 in., resulting in a gauge of only 4 ft. 7½ in. in the straight track between the frogs. This is no hypothetical case, but along with other mistakes of its kind is almost of constant occurrence with young and inexperienced engineers. To avoid such trouble, stakes marking position of frog should be set for actual point and plainly marked to that effect. When the location of a frog in the existing track

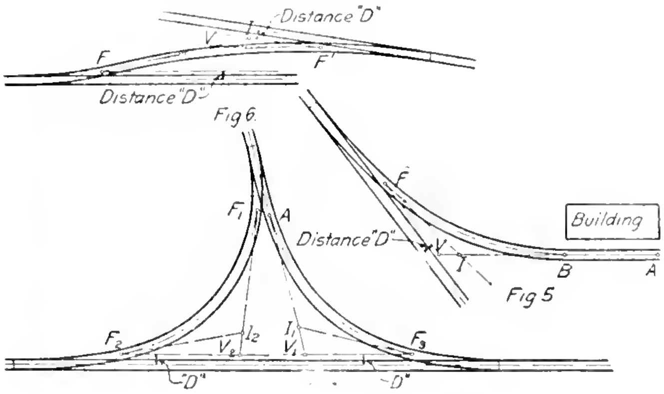


Fig. 7.

is not definitely fixed by conditions, the point of the frog should be so located as to bring the heel or the toe at a rail joint. If this is done, only one rail cutting is necessary and no short rails are required.

Graphical Solution of Track Problems.—A great many track problems can be readily solved by graphical methods. With careful and accurate drafting on a large scale—say 10 or 20 ft. to the inch—many complicated problems are readily solved with all the accuracy usually required in track work. In a great many problems a solution can be easily and quickly effected by making a few trials in the field. In such cases it has been the writer's practice to carry with him in the field a few curve templets, scale, triangle and drawing paper, and by locating the critical or determining points and plotting them to scale, he has generally been able to decrease the number of trials necessary for a solution to one or two.

In staking out tracks to and around existing structures the young and inexperienced engineer may not appreciate the importance of proper clearance and many a track has been staked and afterwards built 6 in. to a foot or more too close to an existing structure.

General Methods.—The ordinary method of locating turnouts where the position of the frog in the main or body track is not a critical feature is as follows: Set up the instrument at A (Fig. 2), this point being in the centre line of the turnout track opposite the point of the frog. Foresight is taken on point B gauge distance from the centre line of main or body track, with the vernier set at minus the frog angle so that when the reading is turned to zero the line of sight is in the centre line A-C of the turnout track. If, now, the turnout track is to proceed on a curved alinement, deflections may be turned either right or left and the curve located. A stake set back a distance from A equal to the length of the lead locates the switch point and the track foreman lines the curve between the heel of the switch and the toe of the frog, either by eye or by using a series of ordinates from the main track rail. If the main or body track is curved (Fig. 3), a backsight D and a foresight B are set, making the distance A-D equal the distance A-B. The angle between the line A-B and the line D-A extended is bisected to obtain a line parallel to the tangent to the main track rail at the point of frog and the frog angle F is then turned off from this tangent line. The work of locating the turnout track is thus done with one set up of the instrument, entirely independent of any theoretical assumption regarding the curve in the lead.

To make the curve (if any) in the turnout track tangent at the heel of the frog instead of at the point, which many would consider better practice, it is only necessary to have a table as in Fig. 4, and using the offset D, proceed as before.

In locating close connections between tracks and sharply curved branch tracks running into or along buildings where the exact position of the frog is a critical feature of the work, this position may usually be obtained as follows: Let A-B (Fig. 5) be the centre line of a branch track whose position for the distance A-B is determined by the building. Extend line A-B towards the main track to point V at distance D from the centre line of the main track. Measure the angle V and the distance VB. Let I be the point of intersection of the line AV with the line FI, angle IFV being the frog angle. Now the criterion for the minimum degree of curvature in the curve FB is that the point of intersection I shall be equally distant from the points F and B. This makes the curve FB a simple circular curve. To solve the problem, let FI = IB = T and let measured distance BV = M.

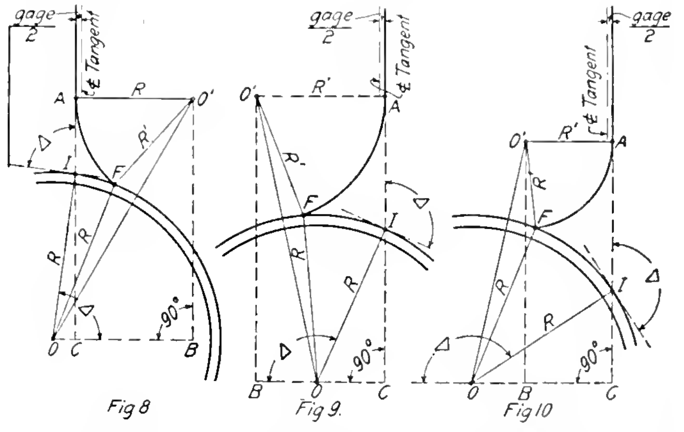
Then VI = M — T: and in triangle FIV we have:

Angle I = angle V + angle F, and

$$\frac{T}{\text{Sin } V} = \frac{M - T}{\text{Sin } F},$$

from which the tangent distance T may be obtained. After thus solving triangle FIV, first for T, then for distance FV, the frog may be located by measurement from the established point V. This method of treatment is applicable to crossovers between non-parallel tracks (Fig. 6), to wye tracks (Fig. 7), and to crossovers between parallel tracks where frogs or unequal angles are used.

In applying the problems, as found in the field books, where a turnout from a curved track is to form a connection with an established tangent, the engineer is restricted to the use of but one curve, the degree of which is that of the theoretical curve of the turnout, which equals the degree of curve of turnout from a straight track, plus or minus the degree of the curve of the track from which the turnout springs. The use of this one curve will rarely prove desirable on account of its being either too sharp or too flat.



[Case 1. Curves in Opposite Directions. Δ less than 90°.] | [Case 2a. Curves in Opposite Directions. Δ greater than 90°, R¹ greater than R cos Δ.] | [Case 2b. Curves in Opposite Directions. Δ greater than 90°, R¹ less than R cos Δ.]

Four general cases of the problem present themselves, as shown in the illustrations, Figs. 8, 9, 10, 11, 12, 13. The necessary field work in each case consists in measuring the angle between the centre line of tangent and the tangent to the centre line of the curve at the point of intersection; or better yet, the angle between a line offset one-half the gauge from the centre line of the tangent and the rail which will

pass through the frog, as the latter will simplify the problem, and the radius of the rail is determined simultaneously by measuring the middle ordinates for one or more chords.

Having the angle of intersection, as described above, the radius of the curved track, and the angle of the frog to be used, and having selected a radius for the connecting curve, the essentials of the location are the distance between the point of intersection and the point of the frog, the central

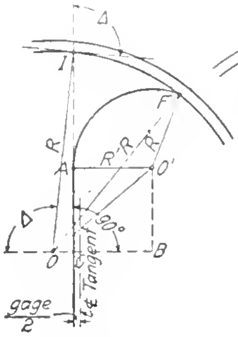


Fig. 11.

[Case 3. Curves in Same Direction. Δ greater than 90°.]

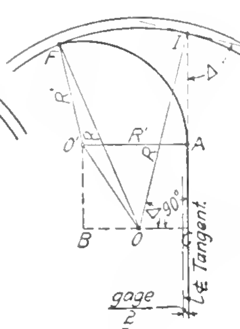

Fig. 12.

[Case 4a. Curves in Same Direction. Δ less than 90°. R^1 greater than $R \cos \Delta$.]

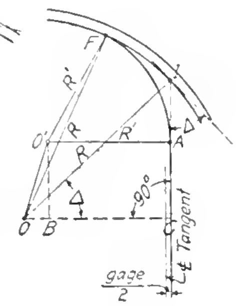

Fig. 13.

[Case 4b. Curves in Same Direction. Δ less than 90°. R^1 less than $R \cos \Delta$.]

angle of the connecting curve and the distance between the point of intersection and the B. C. of connecting curve.

The following solutions offer ready and accurate methods of obtaining the above-named points:

In Figs. 8, 9, 10, 11, 12 and 13 let CA represent a line offset one-half the gauge from the centre line of tangent, which is to be connected with the gauge line of the rail of the curved track by means of a frog having an angle of F and a curve whose radius is R. O and O^1 are the centres, I the point of intersection where the angle Δ has been measured, and the other notations are as shown in the diagrams. The rail opposite the frog and the switch rails are not shown as they have no bearing on the problem. Required to determine the angle I O F. Then measure on the curve:

Arc F I = R $\times$ angle I O F in minutes $\times$ a constant ($=$ 0.00029089).

Or chord F I = 2R $\times$ sin ½ I O F.

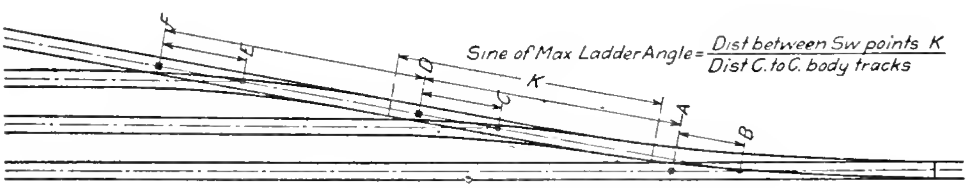

Fig. 15.

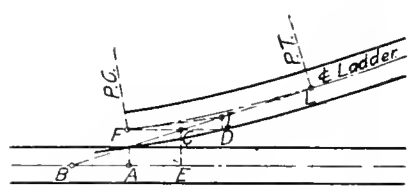

Fig. 16

The distance OO^1 is determined by solving the triangle OFO^1 of which the angle F and its including sides R and R^1 are known. This also determines the angles FO^1O and FOO^1.

In cases 1 and 3, Figs. 8 and 11, $O B = B C + O C = R^1 + R \cos \Delta$

In cases 2a and 4a, Figs. 9 and 12, $O B = B C - O C = R^1 - R \cos \Delta$

In cases 2b and 4b, Figs. 10 and 13, $O B = O C - B C = R \cos \Delta - R^1$.

It should then be noted that when O B is computed to be greater than O O^1, impossible conditions have been imposed; the radius of the connecting curve has been taken too large.

Having determined the angle O^1 O B from the right triangle O B O^1, in which O B and O O^1 are known, the angle I O F is found as follows:

In cases 1 and 2a, $I O F = \Delta - (F O O^1 + O^1 O B)$.
In cases 3 and 4a, $I O F = 180° - (\Delta + F O O^1 + O^1 O B)$.
In case 4b, $I O F = O^1 O B - (F O O^1 + \Delta)$.
In case 2b, $I O F = \Delta - (180° - O^1 O B + F O O^1)$.
In cases 1 and 2a, $A O^1 F = O^1 O B - F O^1 O$.
In cases 3 and 4a $A O^1 F = F O^1 O - O^1 O B$.
In case 4b, $A O^1 F = F O^1 O - (180° - O^1 O B)$.
In case 2b, $A O^1 F = 180° - (O^1 O B + F O^1 O)$.

To determine the distance AI:

In cases 1 and 2, $A I = A C - I C = O^1 B - I C$, $= O^1 O \sin O^1 O B - R \sin \Delta$.

In cases 3 and 4 $A I = I C - A C = R \sin \Delta - O^1 O \sin O^1 O B$.

The engineer should be careful to add or subtract one-half the gauge to the centre line radii, as the case may require. The point A which is the B C. of the connecting curve, and the point F, which is the theoretical point of frog P. T. of the connecting curve can now be readily fixed in the field and the entire connection staked out.

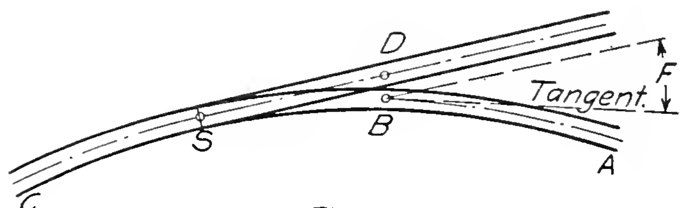

Fig. 14.

While the writer realizes that it is better practice to place the frog end of the connecting curve at the heel of the frog, to impose that condition in the above problem would complicate it beyond measure. In inserting 10 or 15-ft. frogs in a curved track, the trackmen cannot help slightly changing the original alinement of the track at that point, and energy spent in making a closer solution than that outlined above will surely be wasted.

Method of Obtaining Straight Leads.—Theoretically, a turnout leading off the outside of a curve, the degree of which is equal to that for the turnout from straight track will have a straight lead. Practically, however, the lead will not be straight, but curved to a greater or less extent. This is due to the fact that switch rails and frogs are straight and not curved as is generally assumed. When it is possible to do so, it is desirable from both the operating and maintenance standpoints to obtain absolutely straight leads. To obtain straight leads in turnouts leading off the outside of a curve where the main curve is also being staked at the same time, the following method will prove effective. (See Fig. 14).

After staking out the main curve ABC to B, the point decided upon for the location of the frog, set up the instrument at D, this point being in the centre of the turnout track opposite the point of frog. The frog angle is now turned off from a line through D parallel to the tangent to the curve at B, and the point S is located a distance equal to the length of the switch lead from point D. The instrument is now set up at S, and the main curve is continued from the line DS, or switch lead, after which the alinement of the turnout beyond the frog can be proceeded with.

Where conditions permit, it is desirable to have the alinement of crossovers between frog points straight. In the case of crossovers between parallel curved tracks, it is not generally possible to meet this requirement using standard frog numbers, a special frog being necessary in such cases. The writer has known of a number of instances where this requirement of straight track between the frogs of a crossover was of sufficient importance to justify the ordering of the special frog necessary, frog points being comparatively close together in most crossover work.

Ladder Tracks.—In order to obtain the maximum car capacity of the body tracks connected to a ladder track, the angle of the ladder track should be made the greatest possible under the conditions. The criterion for maximum ladder angle is given by the formula (see Fig. 15):

$$\text{Sine of maximum ladder angle} = \frac{\text{Distance between switch points K}}{\text{Distance centre to centre of body tracks.}}$$

In order that road engines may operate over the ladder track it is desirable that the curve beyond the main track frog be made as light as possible. In a number of extensive ladder layouts the writer has used two and three degree curves in such places with very good effect. The method of staking out such ladder tracks is as follows:

After locating the position of the main track frog the point of intersection of the centre line of the ladder track with the centre line of the main track, B, is found by measuring off the distance AB. The instrument is set up at B, the ladder angle turned off and the frog points along the ladder located by measuring the computed distances from B. At the same time the points of intersection of the centre line of various body tracks with the centre line of the ladder track are located by measuring the distance DC, FE, etc., from the frog points. The curve beyond the main track frog is now located. The instrument is then set up at the points C, E, etc., and the body tracks staked out by foresight established at the opposite ends of these tracks by measuring over the respective track centres of each track from the main track. The curves connecting the various body tracks to the ladder track being very short, it is sufficient to locate only their middle and end points.

To compute the distance AB (Fig. 16), let

T = Tangent distance of curve FL
ICD = Ladder track angle

Then

$$\begin{aligned} DI &= T \sin F \\ FD &= T \cos F \\ CD &= DI \cot ICD \\ FC &= FD - CD \\ AB &= BE - AE \\ &= \text{gauge} \times \cot ICD - FC. \end{aligned}$$

While the writer believes that the above method of laying out ladder tracks represents the best practice, there are a number of engineers who prefer to make the ladder angle equal to the angle of the frog to be used in the ladder track, thus making the ladder track frogs line up straight with the body tracks. The central angle of the curve beyond the main track frog is then simply the difference between the angles of the main and ladder track frogs. However, the writer sees no justification in sacrificing valuable ground space and consequent car capacity for the little, if any, advantage that is gained by eliminating the slight curve beyond the ladder track frogs. Those who favor this method claim that by the elimination of this curve in the body tracks, switching operations are rendered more safe by reason of the better views afforded trainmen. However, the writer believes this apparent advantage is more imaginary than real.

CONTROL AND REGULATION OF NIAGARA RIVER.

Hearings were held on January 22 and 23 before the United States House Committee on Foreign Affairs on the new bill controlling the diversion of water on the American side of the Niagara River and the importation of electricity from Canada. The Burton Act expires by limitation on March 4, and a fight is in progress to take from the federal government the control of the diversion of water in navigable rivers and, in the Niagara Falls case, vesting it in the State of New York. The Secretary of War has appointed a board to report upon the problem of diversion of water from Niagara Falls, consisting of Lieutenant-Colonel Mason M. Patrick, Colonel Francis J. Kernan and Major Charles Keller, all of the Corps of Engineers, U.S.A.

The treaty between Great Britain and the United States authorizes the United States to permit the diversion of not more than 20,000 cubic feet of water per second, while the Canadian government is empowered to authorize the diversion of not more than 36,000 cubic feet per second. At present the diversion on the American side of the Niagara River aggregates 15,600 cubic feet per second. The bill now before Congress does not permit the diversion of any more than that amount, and whereas the Burton Act permitted the importation of a maximum of 35,000 h.p. from Canada, the present bill limits the amount to 200,000 h.p. It also makes it obligatory for the generating companies to utilize the water at its maximum efficiency and stipulates that the companies receiving permits for the transmission or delivery of electrical energy shall be regulated to rates, etc., by the Public Service Commission of the State, or where such a commission is lacking by the governor of the State.

At the hearing on January 22 the State of New York through its attorney-general claimed, after the government has decided how much water may be diverted from the Niagara River, that it is entitled to control the diversion of the water and to decide the parties to whom it shall go. It was contended that while the federal government has a right to determine the quantity of water that may be diverted from a boundary stream in the exercise of its constitutional rights to control navigation, that power is exercised pursuant to that constitutional right only for the purpose of regulating and controlling navigation and for no other.

The president of the New York State Conservation Commission expressed opposition to any legislation which will permit the existing generating companies to get any additional water from Niagara Falls. He said that the present policy of the State is to utilize all the undeveloped water-powers for the benefit of the people generally. The generation of electricity which is to be transmitted to the various municipalities and through them to the ultimate consumer at practically the cost of its development. He also maintained that true conservation presupposes the utilization of all the water permitted by the treaty at its maximum efficiency.

It was brought out at the hearing that the taxes of the Niagara Falls Power Company to the State and municipalities aggregate \$3 per horse-power, while the Canadian government charges practically \$1 per horse-power. The Cataract Power and Conduit Company, which distributes Niagara energy in Buffalo, pays the Niagara Falls Power Company \$16 per horse-power-year and sells it at practically \$25 per horse-power-year, the difference being used to pay all the charges of transformation and transmission to Buffalo and its distribution in that city. The Hydro-Electric Power Commission of Ontario pays \$9.40 per horse-power-year for energy to the Ontario Power Company delivered at the terminals of the transforming apparatus, or practically at the power house.

It was also pointed out that the Ontario Power Company generates 17 h.p. for every cubic foot of water per second that is used, whereas the Niagara Falls Power Company is able to generate only about 11½ h.p. for every second-foot of water used.

NEW BUILDINGS OF THE CANADA FORGE COMPANY.

The Canada Forge Company, Limited, Welland, Ont., are rushing to completion a temporary building to replace the one recently burned, and will positively have a part of their forge department in operation within a week, which is record time. This quick work will enable them to satisfactorily care for the delivery requirements of their many customers.

This building will be covered within ninety days by a modern fireproof steel construction forge shop of the most advanced type, contract for which has been placed with the Standard Steel Construction Company, and especially designed for the manufacture of forgings up to 40,000 pounds in weight each.

The general dimensions of this building will be 100 feet by 200 feet, with centre bay equipped with 20-ton electric crane 60-foot span, with two bays each to be served with five-ton electric crane, 20-foot span.

At the end of this building and continuing a distance of 100 feet, there will be constructed a 60-foot span electric crane runway 20-ton capacity for handling raw materials and shipping.

This will not only insure the company against further interruptions in their production, on account of fire, but will greatly increase the scope of their work; and equipped as it will be with steam hammers, hydraulic forging presses, annealing and heat treating furnaces, it will be one of the finest forge shops on this continent.

WANT SHIPBUILDING ENCOURAGED.

A deputation, representing shipbuilding interests from coast to coast, has waited on Premier Borden. They state that the Canadian shipbuilding industry, in which twenty million dollars are now invested, will go out of business unless protected against British and United States competition, and encouraged by way of a government subsidy or bonus on a tonnage basis.

The government were asked to take prompt action to prevent the practical disappearance of the industry in Canada, and the deputation maintained that under existing conditions of competition with Great Britain a government encouragement to the extent of about 20 per cent. of the cost of building iron and steel vessels in Canada should be given either by way of subsidy or by way of tariff protection.

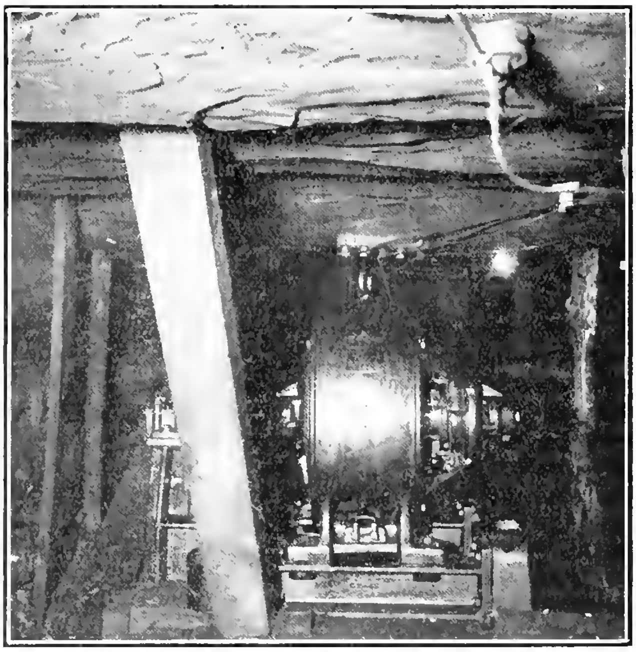
Premier Borden promised careful consideration of the written brief submitted by the deputation, coupled with a suggestion that the government might well adopt a policy of having all government vessels built in Canada, even if the cost was a little more than if the orders were placed in Great Britain.

The English shipbuilding firm of Swan, Hunter and Wigham Richardson are considering entering the Canadian shipbuilding trade, according to the statement of Mr. Clarence I. DeSota, Canadian director of the firm.

SELF-STARTING DIRECT-CURRENT MOTORS FOR DRIVING MINE PUMPS AND FANS.

The electric motor has proved so thoroughly satisfactory for driving mine pumps and fans that it seems almost impossible to improve it. It can be placed wherever a pump or fan can be located; a couple of wires supply it with the power it needs; and when running it requires no attention whatever beyond occasional inspection and oiling. In fact, motors have proved themselves so useful and economical that they are rapidly displacing all other forms of power for fan and pump service wherever electricity is available.

An improvement has, however, been recently developed which greatly increases the value of motors for mine work. This improvement consists in making the direct current motors self-starting.



Heretofore, while it has been possible under some conditions to start them from the power house, most motors driving nine pumps and fans had to be started by hand. Hence, if the power went off temporarily for any reason, the motors stopped, necessitating an attendant to go to each station to start them again.

With the new self-starting D.C. motors, this inconvenience is done away with. When the power fails, the motors stop, it is true, but as soon as the power comes on again, the motors start automatically and settle down to work as though nothing had happened. Moreover, starting boxes are rendered unnecessary, and the wiring is of the simplest possible character. An occasional visit of inspection is now all the motors require. Otherwise they can be left entirely to themselves.

These motors have been thoroughly tried out in practical service and their uses are commending them highly, as is shown by the number of repeat orders the mannfacturers are obtaining.

The electrical characteristics of the self-starting motor differ but little from those of the usual type, the only alteration being in the use of a heavier compounding winding which reduces the flow of current when starting. Mechanically, there is no change.

Self-starting motors are made by the Westinghouse Electric and Manufacturing Company, East Pittsburg, Pa., in ratings up to 20 horse-power for the voltage usually employed in mine work. They can be supplied for all kinds of pump and fan service.

COAST TO COAST.

Ottawa, Ont.—Western votes in the main estimates include an appropriation of $10,000 for a new dredging plant for Manitoba, Saskatchewan and Alberta, and $50,000 for improvements to Rainy River.

Boston, Mass.—President Chamberlin, of the Grand Trunk Railway, has raised $6,000,000 to help in the fight of extending the Grand Trunk lines through New England to Boston. The interests opposing this move are large and powerful and will put up a strenuous opposition to the Grand Trunk.

Windsor, Ont.—The Remington Arms Union Metallic Cartridge Company, of New York, have purchased a site for a large plant here and will enter the Canadian field on an extensive scale. No high explosives of any kind will be used and no powder manufactured in Windsor, and ample precautions to guard against possible explosions have been arranged for.

Winnipeg, Man.—Petitions are being circulated to have the duty of 52½ cents per barrel on American cement reduced to 26 cents, so that American cement can be shipped to Canada at a fair profit. This is due to the fact that nearly all the municipalities in the Dominion are looking forward to a banner road-building and construction year, of which cement forms the chief material and Western Canada fears another cement famine unless American cement can be shipped here, but which the present duty prohibits.

Chicago, Ill.—That the Canadian Pacific Railway will have one of its largest terminals in Chicago is indicated by recent purchases of real estate. The Central Terminal Railway, a local corporate name of the Canadian Pacific, has bought three full blocks on the west side. The company has now bought thirteen additional parcels of land near Fifteenth and South Union Streets. The entire property will be used for freight terminals, according to present plans. In addition to down-town land, the company is purchasing property at Harvard Street and West Forty-eighth Avenue for auxiliary yards. To date, the company has bought 252 parcels of land in Chicago at a cost of $2,480,681.

DOMINION SAWMILLS COMPANY REORGANIZED

The receivers, managers and the liquidator of the Dominion Sawmills and Lumber Company, Limited, announce that the following have been appointed as the board of Forest Mills of British Columbia, Limited, successors to the business heretofore carried on by the former corporation:—Messrs. J. M. Savage, of Victoria, chairman; R. S. Lennie, barrister; W. J. Blake Wilson, T. Frank Patterson, all of Vancouver, and W. A. Anstie, of Calgary.

Mr. Anstie will occupy the position of executive agent of the board with headquarters in Vancouver. The receivers express their appreciation of the support accorded them during the period of their management of the business which has now terminated.

The Forest Mills of British Columbia, Limited, owns extensive timber tracts in the interior in proximity to its five sawmills located at Three Valley, Taft, Comaplix, Cascade and Nelson respectively, as well as an organization for selling the output in the local and prairie markets.

The bonds of the Dominion Sawmills, Limited, were practically all sold in Great Britain, and the failure of the company did not help the cause of British capital in Canada.

DOMINION TAR AND CHEMICAL COMPANY.

The timber preserving plant at Sydney of the Dominion Tar and Chemical Company, Limited, is far from being unable to accept orders, but is ready and anxious to treat all classes of timber, railroad ties, bridge timbers, piling, sheathing, etc.

It is not the only plant of its kind in Canada, as the Dominion Tar and Chemical Company, Limited, has a larger plant at Transcona, near Winnipeg, where they have three large treating cylinders operating, creosoting ties and other timbers chiefly for use of the Canadian Pacific Railway. The treating plant at Sydney is an adjunct to a large tar distilling plant of the company which produces in large quantities the creosote oils used in the preservative treatment of timber.

The company has another large tar distillery at Sault Ste. Marie, Ont., engaged in the same operations, except that there is no timber treating plant at that point.

PERSONAL.

JAS. McKEOWN has been appointed superintendent of highways in Welland County, Ont.

E. J. PHILLIPS has been appointed manager of the Berlin, Ont., light and water department to succeed C. T. Wilkinson.

JOHN McKAY, engineer of the trunk sewer, Regina, Sask., has been appointed superintendent of the Regina waterworks.

GEO. ROSS, Associate Member of the Canadian Society of Civil Engineers, has been placed in charge of roadways in Welland County, Ontario.

J. R. WEMLINGER has been re-elected for the second time secretary of the American Society of Engineering Contractors, with headquarters at 11 Broadway, New York.

FRANK H. MARTIN, superintendent of the Toronto Power Company's hydro-electric plant at Niagara Falls, has returned after a six weeks' trip to Bermuda on account of his health.

A. W. ELLSON FAWKES, chief assistant engineer in charge of the mechanical water filtration scheme at Minneapolis, has been appointed waterworks engineer for the city of Calgary.

W. ARMSTRONG, of the Canadian P. J. Mitchell Company, Montreal, will sail for England in about two weeks on business concerning the lines manufactured by Richard Garrett & Sons and Lassen & Hjort.

ALLAN McQUEEN, B.A.Sc., an honor graduate of the School of Practical Science, Toronto University, 1912, has been appointed assistant power engineer of the city light and power system, of Winnipeg, Man.

GEORGE W. FULLER, of New York City, has been retained as consulting engineer to prepare plans and specifications for the 12,000,000-gallon, slow sand filtration plant to be built at Evanston, Ill. Mr. Langdon Pearse will be associated with him on the work.

CANADIAN MINING INSTITUTE.

The annual meeting of the Canadian Mining Institute will be held at the Chateau Laurier, Ottawa, on March 5th, 6th and 7th. The meeting will be opened by H.R.H. the Duke of Connaught. The papers read and discussions will deal with mining industries in the vicinity of Ottawa, including mica and graphite; ore dressing subjects, especially the treatment of the gold ores of the Porcupine district, and the silver ores of the Cobalt district; mining and metallurgy of iron.

ENGINEERS' CLUB OF TORONTO.

The annual meeting of the Engineers' Club was held on the 6th inst., and the annual report for 1912, which showed a very successful year, was discussed. Five new directors were chosen for the coming year: Messrs. Willis Chapman, Hustace G. Bird, E. T. J. Brandon, W. T. Ferrier, and Jas. Milne. The officers for the coming year will be chosen by the directors at the next meeting.

CANADIAN FORESTRY ASSOCIATION.

The annual business meeting of the Canadian Forestry Association was held at Ottawa, February 5th. The election of officers resulted in the choice of Hon. W. A. Charlton, vice-president, as the new president, and W. Power as vice-president. On the board of directors Messrs. J. B. White, E. J. Jarvis, R. D. Pretty, H. R. MacMillan, of British Columbia, and G. Colquhoun were added to the list. The secretary, Mr. James Lawler, was re-elected.

COMING MEETINGS.

ILLINOIS WATER SUPPLY ASSOCIATION.—The Fifth Annual Meeting of the Association will be held at the University of Illinois, Campaign-Urhana, Ill., March 11th and 12th, 1913. Secretary, Edward Bartow.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb 26th to Mar. 8th.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.—Annual Meeting will be held March, 3, 4 and 5, 1913, in the Green Room, Congress Hotel and Annex, Chicago Ill. Secretary, Will P. Blair.

CANADIAN MINING INSTITUTE.—Annual Meeting will be held at Chateau Laurier, Ottawa, March 5th, 6th and 7th. H. Mortimer Lamb, Windsor Hotel, Montreal, Secretary.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St., Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Bravley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P. O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chas. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

NOTES ON HEADGEARS FOR COLLIERIES AND OTHER MINES.

By F. TISSINGTON.

The headgear or frame supporting the pulleys around which pass the ropes attached to the cages for the conveyance of men and material to and from the working level is generally the most important structure in any mining equipment, as on its utility and stability depends the entire output of the mine as well as the safety of the men working underground.

Under these circumstances, therefore, it will be readily seen that it is not a wise policy to attempt to skimp the material, design of details, or execution of the work in the shop, but, in view of the indeterminate nature of the vibratory stresses on the structure and the sudden application of loads, good allowances should be made for impact and low unit stresses adopted generally.

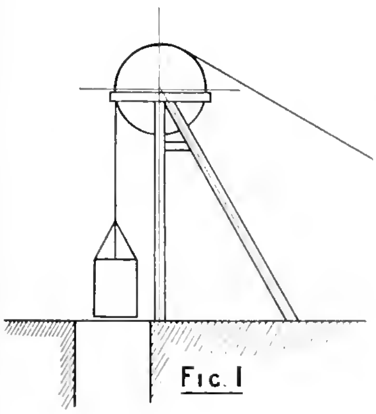

Fig. 1

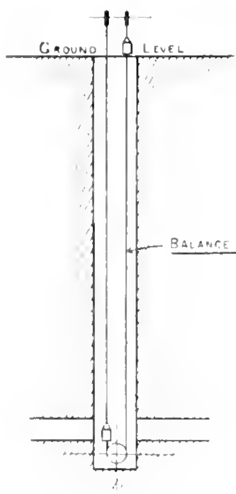

Fig. 2

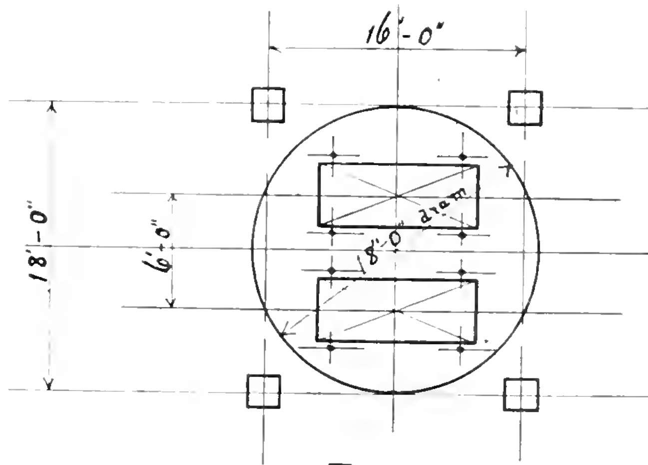

Fig. 3

Quite a large amount of the detail work is purely derived from experience and practical requirements, and this will be referred to in detail later.

Probably the earliest form of headgear consisted of a timber frame built up in the manner shown in Fig. 1. The writer has seen quite a number of this type, ranging from about fifteen to thirty feet high, with more or less detail, according to the loads carried. Generally, however, the speed of winding was very slow and the loads light; also, each frame carried one pulley only, so there was no necessity for much equipment in the way of guides.

As the seams near the surface were worked out and the demand for coal grew, a gradual evolution took place in all colliery equipment.

With the increased depth and greater time occupied in winding the material to the surface, the desire to carry more coal per trip arose, and consequently we see to-day collieries with winding plants capable of handling three and four loaded tubs per trip and landing same at the pit mouth from the working level, which may be anything up to about three parts of a mile, well under a minute.

Double, and even treble, decked cages are to-day quite an ordinary event, and occasionally you will find a plant where two pit tubs or corves are carried on each deck, each containing about 1,600 or 2,000 pounds of coal, and, with the cage, chains and rope, making in all somewhere around 30,000 to 40,000 pounds of dead weight to move on the loaded side of the shaft.

Practically all modern plants are designed with two sheaves or pulleys on the headgear, each provided with a rope supporting a cage, arranged so that when one is at the top of the shaft the other is at the bottom, and thus to a large extent they balance each other, so far as the winding engine is concerned, as the two ropes are led to two drums, mounted side by side on the same shaft, one being taken over the top side of the drum on the one side, and the other led underneath the other drum, so that as soon as one rope unwinds the other winds up.

The amount of the unbalanced load is measured by the quantity of coal carried per trip and the difference in the length of the rope from the supporting pulley on the headgear to the cage.

Sometimes, however, the latter is also balanced, and this is done by attaching another rope to the bottom of each cage and passing same around a pulley in the bottom of the shaft exactly as shown in Fig. 2.

With the operation of two cages in one shaft came the necessity for the addition of guides to prevent the cages swaying about at the end of the ropes and clashing together as they passed each other.

These guides are of two general types. (1) The timber, or rail guide, which is fastened to cross pieces, called "buntons," let into the wall of the shaft at intervals to suit. These are not supported by the headgear, and, therefore, do not concern us.

(2) The other type is the guide-rope. Generally a set of these for each cage consists of four ropes, but for the larger cages six or more may be used. These are suspended directly from the headgear frame at a point just below the pulley platform. To the lower end of these ropes are attached cast iron weights in order to keep them taut and hanging vertically. Sometimes as much as ten or twelve tons will be suspended at the end of each rope, and, with the weight of the rope itself, these guides form quite a formidable load to design for. The guide-ropes, like the

Where P = effective pull in pounds causing motion.
T = Tension on the rope in pounds.
A = Acceleration of load in feet per second in a second.
W = Weight of cargo, load, and rope in pounds.
G = 32.

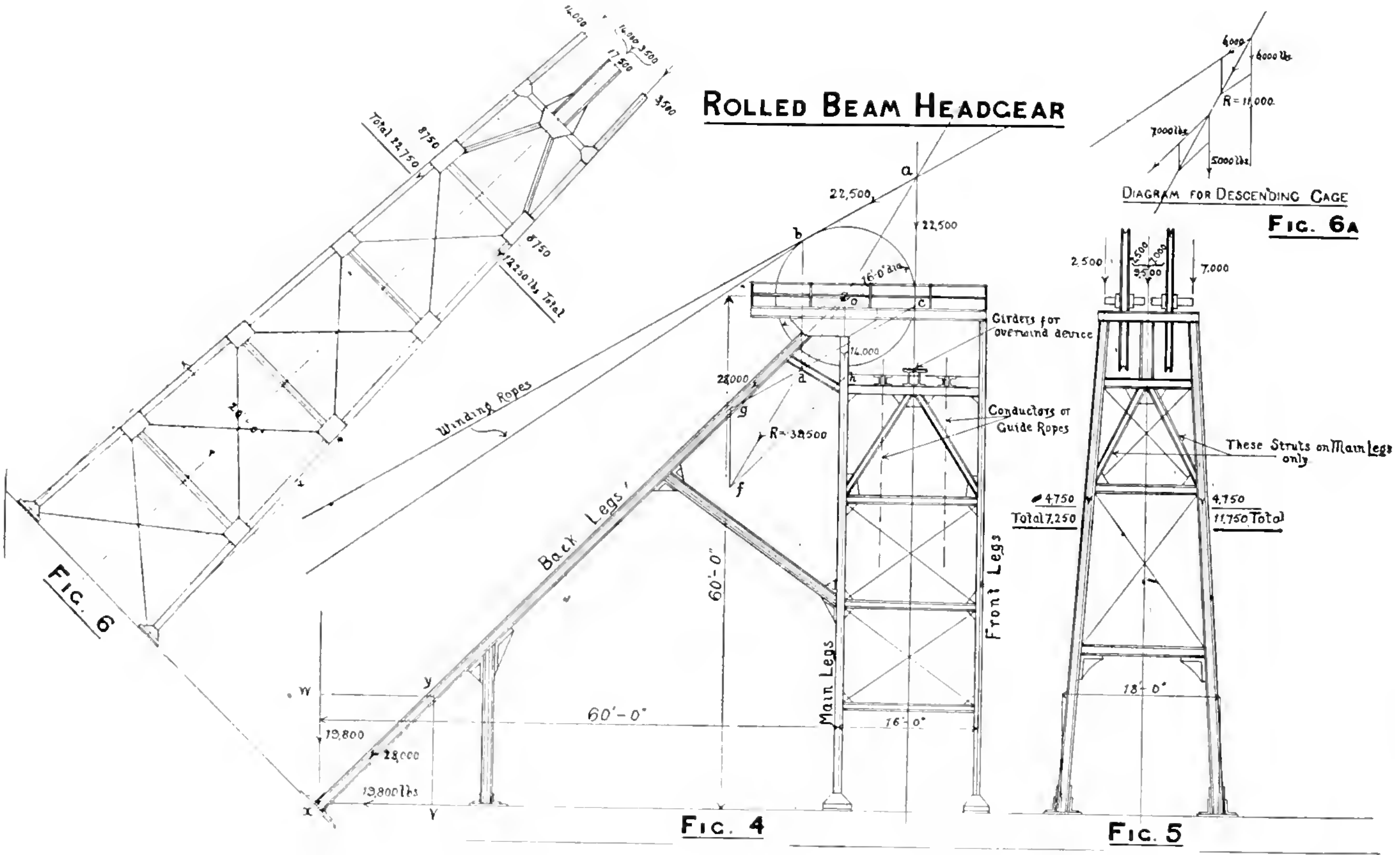
$$\text{Now } P = T - W,$$

$$\text{and also } P = \frac{WA}{G};$$

$$\text{therefore } T - W = \frac{WA}{32},$$

$$\text{or } T = W\left(1 + \frac{A}{32}\right)$$

It will be seen from this formula that if we take unit weight, then when the acceleration reaches, say, 32 feet per second, the tension in the rope will be twice that for load at rest.



winding ropes, are all made of steel, and the diameter will be anything from one inch to an inch and a half.

With all winding or hoisting engines there is an increase in stress on the hoisting rope, due to the acceleration of the load, and this may amount to half the dead load suspended from the rope.

It has also been demonstrated that quite a large increase in stress is due to the vibration of the cage, caused by the pulsation of the engines, and this is very similar in effect to a piece of elastic held in the hand with a weight suspended at the free end, when a slight movement of the hand will cause the weight to jump about for a considerable period after the cause is removed. These pulsations are much more noticeable with engines of an inferior type, and also with the sudden application of the brakes or checking the speed by shutting the steam valve quickly. With an increase in load the vibrations appear to become less.

The increased stress on the rope due to acceleration may be found by the following method:—

Therefore, knowing the acceleration of the cage and load, and also the total weight to be lifted, the tension in the rope will always be W plus some fraction of W represented by $\frac{A}{32}$. For usual practice this is generally in the neighborhood of one and a half times the load, or the acceleration is approximately sixteen feet per second in a second.

Other loads of an important character are those caused by over-winding, when a safety catch is provided for supporting the cage after the rope has been automatically released, and also the adoption of a safety catch if the rope breaks.

To the tyro it looks a most difficult operation to bring a heavy engine and its load to rest at exactly the right place every time, year in and year out, but with the appliances and safety gear used to-day it really resolves itself into a purely mechanical operation. However, mistakes are

sometimes made, even with the best of men, and the winding engineman is as careful and painstaking as his brother of the railway engine.

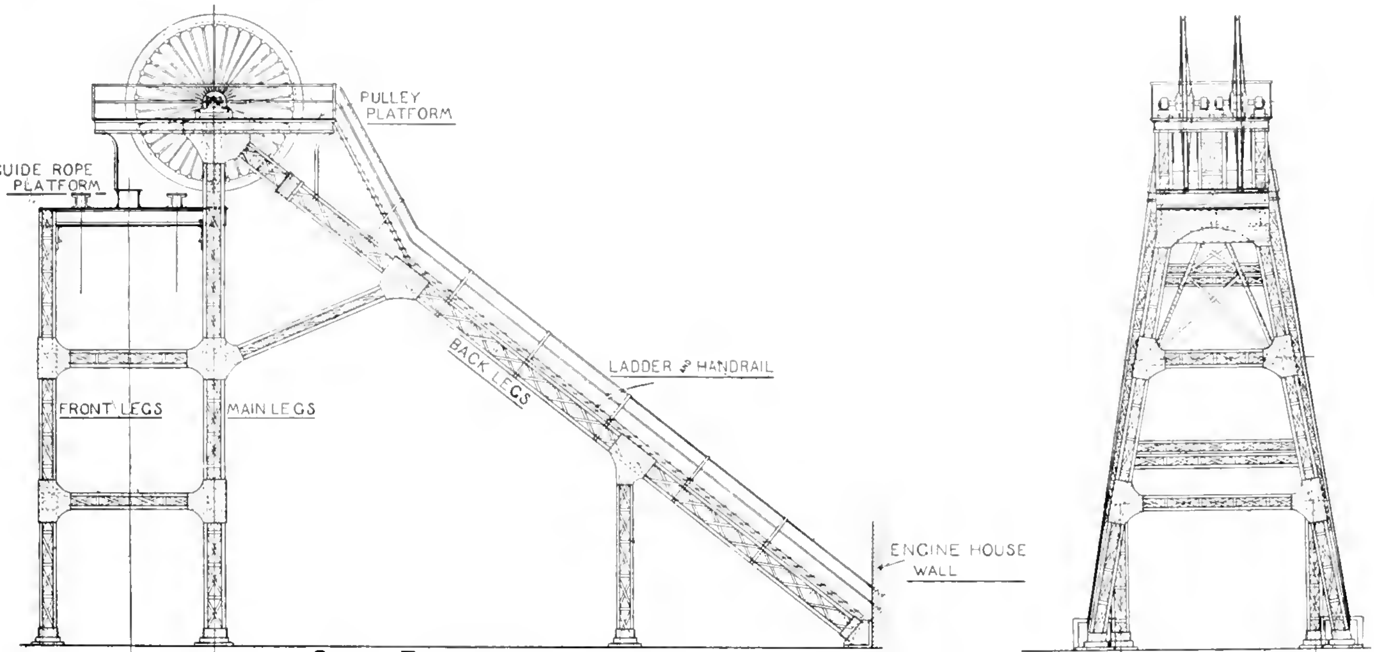
In the early days it occasionally happened that the engineman forgot to shut off his steam soon enough or omitted to apply his brakes in time, and, instead of landing his load either of men or material at the appointed place, brought the cage right over the pulley, or, failing that, broke the rope at the top of the headgear and dropped the cage to the bottom. In order to prevent this the King's safety hook was designed. This is operated by means of a heavy plate having a circular hole cut in same through which the rope passes normally, and is usually placed on the guide-rope platform. In case of an over-wind the catch, or safety hook, passes through the plate until the sides come into contact with same. This causes the rope to be released at the top, and also spreads out the part of the hook above the plate, at the same time providing a lug or catch on the safety hook which matches with the plate, and so prevents the cage from falling down the shaft again. This operation causes quite a severe shock to the headgear, as the cage and its contents would actually drop a few

(1) The rolled steel headgear made with I-beams, channels, etc., and braced with angles and tie-rods; and

(2) The lattice headgear, in which practically the whole of the members are composed of four angles, placed to make a box section, and laced together on all four sides with small flats.

Each type possesses particular advantages. That made from rolled I-beams, etc., is easier and cheaper to produce, although the dead weight to handle will generally be greater. The facility with which the connections can be made and the use of standard details to a large extent make it rather desirable from a shop and erecting point of view, but it has one great disadvantage, and that is the lack of stiffness without the insertion of a large excess of weight, which would put it right out of the running. With the advent of the broad flange beams, however, during the last few years this has been improved to quite a large extent.

The greatest detriment to the lattice headgear is the high cost per ton produced, which, however, is offset to a large extent by the decrease in weight necessary to carry a given load, as the disposition of the material more nearly



SIDE ELEVATION FIG. No. 7 FRONT ELEVATION

LATTICE TYPE HEADGEAR

inches, and, therefore, it is necessary in cases where this gear is adopted to allow for this extra load.

The other device, used in cases where the winding rope breaks, produces a stress on the guides, as generally it is of the slipper type, actuated by a spring, and only comes into operation by the rope parting.

The stress in this case also is liable to be very severe, as the rope may break at the maximum speed, and a small fraction of time must elapse before the various parts fulfil their duty, and during that time the cage is increasing its velocity. The action is purely of the character of a brake, and it would be fairly good practice to allow about twice the dead load of the falling cage, chains, rope and load for both cases, and also use a low unit stress on the parts affected.

In addition to the special loads described, the structure will have to be designed to carry its own dead weight, wind and snow loads. The two latter loads, however, are not of a very serious nature as compared with the live loads.

There are two types of steel headgear in general use:—

approaches the ideal form for struts and columns. Other features which prohibit its adoption in many cases are:—

(1) The increased area of metal exposed to the action of the weather, and consequently greater danger of oxidation of the structure.

(2) Painting is also more costly, not only on account of the greater area to cover, but also for the comparative inaccessibility of the various parts.

For a given amount of material there is no doubt but that the lattice structure provides a high degree of stability and freedom from vibration. Taking it all round, there appears to be very little ultimate difference in the two methods, and generally the type is chosen according to the fancy of the purchaser, or settled by the manufacturer to suit his outfit and stock material.

Figs. 4, 5 and 6 show the general outline of a rolled beam headgear, and Fig. 7 is a type drawing of a lattice structure, and from these figures a good idea may be obtained of the usual disposition of the material.

It is now proposed to give the general method of arriving at the total stress on the main members, and we will assume the following figures to form the basis of our calculations:—

	Pounds.
Weight of one cage, empty	4,000
Weight of two tubs, empty	1,000
Weight of rope	7,000
Total descending cage	12,000
Weight of coal per trip	3,000
Total ascending cage	15,000

Acceleration = 16 feet per second in a second.

Therefore, stress or pull on descending rope = 6,000 pounds.

And stress on ascending rope = 22,500 pounds.

Weight of eight guide or conductor ropes and weights = 96 tons.

Height of headgear = 60 feet to centre of pulley.

centre line of shaft, thus making an oblong of eighteen by sixteen feet.

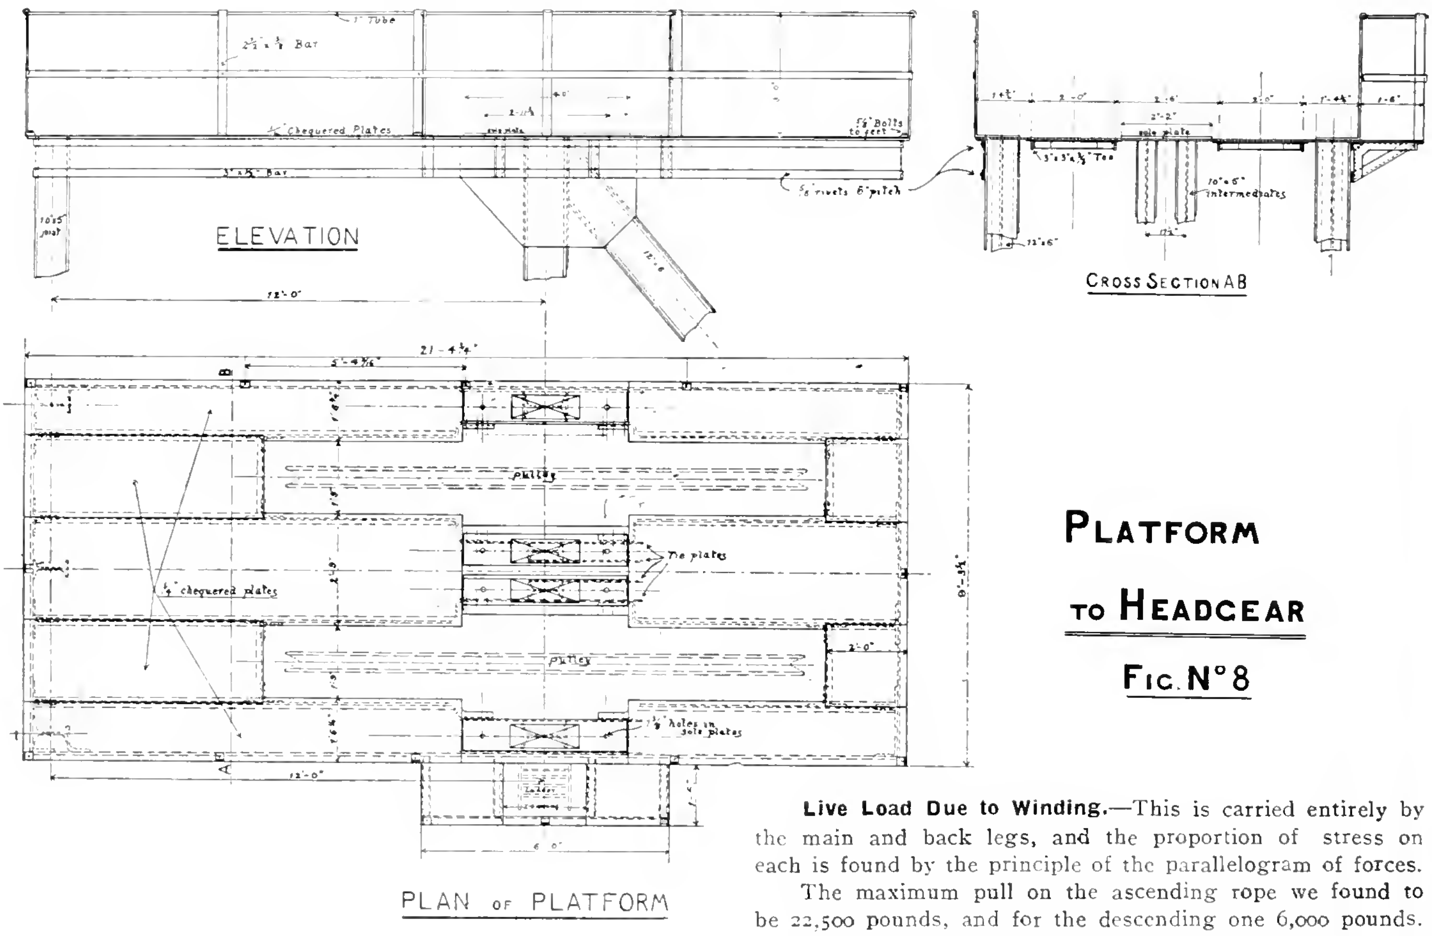
The position of the back legs is generally determined by the wall of the engine-house, which takes up any horizontal thrust there is. Should this support not be available for any reason, separate foundations must be made to carry the loads safely.

Referring now to Figs. 4, 5 and 6, these give the outline of the structure in side and front elevations and a true view of the back legs, respectively.

The short diagonal struts (or spurs, as they are sometimes called), shown in Fig. 4 below the girder for the over-wind gear on the guide-rope platform, are for the purpose of transferring the load from the over-wind girder directly to the main and front legs, leaving only the quiescent load on the conductors to be carried in bending.

The similar struts in the other two views also transfer the loads from the inside bearings of the two pulley shafts direct to the main and back legs without introducing transverse stress.

Having settled the general layout, we will now proceed to find the stresses on the main members.



PLATFORM TO HEADGEAR

FIG. No 8

Diameter of shaft = 18 feet.

In starting to set out our frame the first consideration should be to plant the legs of our structure where they will get a good, solid foundation, and also to give a diameter of pulley for the rope suitable for its size. We will, therefore, assume that it is necessary to have pulleys 16 feet diameter in order that the bending stresses do not run too high. (This information is usually supplied by purchaser.)

If this dimension is plotted down in plan, as shown in Fig. 3, it will be easy to arrive at a suitable figure for the other dimension tying up the position of the four legs round the shaft, so that the bases do not come too close to the edge of same, and it will be noted on referring to the figure that they are placed at nine feet each side of the

Live Load Due to Winding.—This is carried entirely by the main and back legs, and the proportion of stress on each is found by the principle of the parallelogram of forces.

The maximum pull on the ascending rope we found to be 22,500 pounds, and for the descending one 6,000 pounds.

Referring to Fig. 4, and treating the ascending load first, if the lines indicating the rope on both sides of the pulley are produced until they meet, which will be at the point "a," and from this intersection lengths are scaled along both lines to represent the maximum tension in the ropes, as shown by "a b" and "a c," then by completing the parallelogram "a b d c" the resultant of these two forces can be found, namely, "a d," and on being measured by the same scale the magnitude of this resultant is approximately 39,500 pounds. This line, it will be noted, passes through the centre of the shaft, and indicates the desirability of using angular bearings rather than the ordinary vertical type. This resultant can now be resolved into two other components acting in the direction of the main and back legs, respectively.

Starting from the centre of the pulley shaft (which is always made the intersection point of the main and back legs) marked "o," measure along the line "o d" produced the length "o f," which represents by any suitable scale the magnitude of the resultant, viz., 39,500 pounds, and then from the point "f" draw parallel lines with the main and back legs, and the intersection of these lines with the centre lines of the two legs will complete the parallelogram "o g f h," and by the same scale with which the resultant was plotted down the magnitude of the stresses on the two legs are found to be 14,000 pounds for the main and 28,000 pounds for the back legs.

For the descending load the small diagram (Fig. 6a) gives the corresponding figures, and, referring to Figs. 5 and 6, the distribution of these stresses on the two main and two back legs will be seen, and are self-explanatory.

Guide Ropes and Weights.—There are eight of these, four to each cage, and each will weigh twelve tons, complete. Each of the main and front legs will support one-fourth of the total load, viz., 24 tons.

Stress Due to Overwind.—The maximum will be equal to the weight of the cage, tubs and coal, multiplied by two to allow for impact, which will in this case amount to 8,000 × 2 = 16,000 pounds.

Referring to Fig. 4, it will be seen that this load is supported by a heavy cross girder, and the exact distribution will depend on the relative distances between the point of application of the force and the points of support at each end of the girder.

Without having anything more definite we will assume that two-thirds of the load will be carried to one end as a maximum, and this will be equally distributed between one front and one main leg by the action of the spurs or struts referred to previously.

As it will be impossible to get the stress due to winding and over-wind at the same time, it will only be necessary to take the greater of the two, so far as the main legs are concerned, but for the front legs this will be an additional load to allow for.

For the case of the winding rope breaking in the shaft, the distribution of the stresses caused will be practically identical with the above, and the allowance made for the over-wind will answer for this also.

Dead Load of Structure.—This is generally assumed from data obtained in previous cases. For this particular case it may be taken at fifty tons. Approximately twelve tons of this will be carried by the two back legs and the remainder about equally on the main and front legs, namely, nine and a half tons each.

Wind Load.—A maximum of about 30 pounds per square foot of actual area of frame exposed will be quite good practice. As, however, it is rather difficult to obtain this information until the calculations are completed, an assumption may be made that the area exposed equals about one-fifth the total area enclosed by the outside lines of the frame.

By adopting this latter course we find the total area is about 2,800 sup. feet, giving a total wind load of 16,800 pounds.

The centre of gravity of this force will be about halfway between the ground level and centre of pulley shaft, and, therefore, the moment will be

$$16{,}800 \times 30 = 504{,}000 \text{ foot pounds.}$$

This will be divided about equally between the three pairs of back, main and front legs, and, therefore, the maximum stress on any leg will be equal to:—

$$\frac{504{,}000}{3 \times 18} = \pm\ 9{,}333 \text{ pounds, according to the direction of the wind.}$$

Where 18 feet = the centre of the legs at the base in ...

Neglecting snow load, which will be comparatively small for a structure of this class, and tabulating the figures found, we have the following:

Table of Stresses on Front, Main and Back Legs of Headgear.

Nature of stress.	Front legs.	Main legs.	Back legs.
Dead loads—			
Guide-ropes and weights..	48,000	48,000	....
Weight of structure	19,000	19,000	12,000
Total dead load	67,000	67,000	12,000
Live loads—			
Winding stress	....	14,000	28,000
Over-wind stress	2,700	2,700	...
Wind load	9,500	9,500	9,500
Maximum live load	12,200	26,200	37,500
Add 100 per cent. to live..	12,200	26,200	37,500
Grand total	91,400	119,400	87,000

The ordinary methods are now adopted for finding the sections, and a suitable formula would be:—

Permissible safe stress in pounds per square inch =

$$18{,}000 - 70\frac{L}{r}$$

Where L = length in inches between supports,
and r = least radius of gyration of section.

Pulley Platform.—Fig. 8 shows a general plan of a platform from which the construction can be clearly seen. The girders supporting the floor plates are made from angles and web plates. Sometimes, however, and where the details will permit of same, it is cheaper to use channels in place of these built-up girders. Usually, heavy steel plates, half to three-quarters of an inch thick, are laid under the cast-iron sole-plate of the pedestal with the idea of distributing the load as evenly as possible over the intersection of the main and back legs. The floor-plate should preferably be of chequer plate, and if these are judiciously arranged, quite a large amount of stiffness is imparted to the top of the structure to resist the torsional strains due to the unbalanced stresses on the two winding ropes.

Guide-rope Platform.—The construction of this would be similar to the above, and the conductor and over-wind girders would form the supports for the platform.

Practically speaking, neither platform has to support any vertical load other than that of a man walking around or any loads due to repair work going on, and the latter is not likely to be very excessive.

The design of these platforms is largely one of practical experience, and perhaps their most important function is that of a diaphragm, as suggested previously.

The pulley platform may be supported either as shown in Fig. 4 on all six legs, or as indicated in Fig. 7 on the main and back legs only, with the small angle struts inserted as steadiers.

The girders for the guide-ropes and over-wind gear are calculated for in the usual way, the only point to watch being an adequate allowance for the sudden dropping of the cage and its contents on same.

Bracings, Struts and Diagonals.—The whole of these members are put in solely for the purpose of stiffening the structure and reducing the unsupported lengths of the legs.

Generally, the working out of the details will determine to a large extent the best sections to use, and this feature, combined with the general principles of symmetry and proportion and usual practice, will bring about a result which is at once reliable and pleasing to the eye.

RESURFACING OF A TARVIA ROAD IN ST. THOMAS, ONT.

By M. H. Baker, City Engineer, St. Thomas.

In 1912 a portion of Gladstone Avenue, to the extent of 1,681 yards, was re-surfaced with Tarvia X. The portion of the street in question was one of the first macadamized streets laid in St. Thomas, having been constructed in 1894 by Mr. R. W. Campbell, then city engineer. The street provided ample material for the construction of the Tarvia pavement, with the exception of two cars of fine stone which were required for surfacing.

The Tarvia was heated in kettles and applied in the form of a spray by a small tank wagon, provided by the Paterson Manufacturing Company, steam pressure being supplied to the tank by the steam roller. This method is rather costly; the more economical method being to have the material supplied in tank cars and heated by steam.

The surface of the roadway was first swept as clean as possible with hand brooms, then spiked with the steam roller. After the roadbed was thoroughly broken up, it was found to be too dirty to apply the Tarvia, so, all the stone was screened, to remove all dust, loam and fine material. It may be of interest to note that the screenings were found to be of the following composition:—

Moisture	6%
Gravel and coarse sand	58%
Fine sand	15%
Clay and organic matter	21%

The screened stone was then graded and rolled to within two inches of the surface of the completed roadway. This surface was then given an application of Tarvia, and 1½-inch stone filled over this and rolled to approximately the surface of the completed road, and Tarvia again applied. Over this was spread stone chips to cover the Tarvia, and another application of Tarvia lightly sprayed over this. This was all covered with a coat of sand and thoroughly rolled to a smooth, hard surface. After a couple of weeks' traffic had worked the sand into the surface, the street was swept clean, and presented a smooth, hard surface.

The cost of the work was as follows:—

Tarvia	$ 408.50
Freight and cartage on Tarvia, kettles and tank wagon	111.98
Roller (a charge of $10 per day was made on the street)	105.00
Crushed stone	82.29
Miscellaneous (tools, etc.)	13.79
Labor	364.19
Sand	4.00
	$1,089.75

This makes a cost per yard of $.648.

THE SUDBURY NICKEL FIELD.

An important purchase has been negotiated in the Sudbury nickel field during the last two weeks, and is noted in the Engineering and Mining Journal. Dr. F. S. Pearson, who has been closely identified with Sir William MacKenzie in his hydro-electric power enterprises in Canada and Mexico, has taken over the holdings of the Dominion Nickel-Copper Company. It is believed, however, that Doctor Pearson and his former associates will not be called upon to do the financing, rumor having it that the money will be put up by the Rothchilds.

BRICK PAVEMENT FOUNDATIONS.

In commenting on the relative economy of using a sand or concrete foundation under a brick pavement the chief items to consider are first cost, maintenance and life. In the following discussion of the three items of first cost, maintenance and life the experience of the Department of Public Service of the City of Cleveland was described before the American Association for the Advancement of Science by Mr. Robert Hoffman, chief engineer of the Department of Public Service.

The city of Cleveland first began to lay brick pavements in 1889 and has continued doing so ever since, until at present there are about 328 miles of streets paved with brick, subdivided as follows:

257.61 miles, 5-in. brick, sand foundation.
19.39 miles, 5-in. brick, concrete foundation.
39.17 miles, 4-in. brick, concrete foundation.
11.84 miles, 4-in. brick, sand foundation.

Since then prices paid for brick pavements have varied from $1.18 per square yard to $2.48, depending on the various forms of foundation and size of brick used.

The following table indicating the various paving combinations employed in Cleveland for brick pavements shows the yearly average maximum and minimum prices paid per square yard since the year 1900. The cost of excavation assumed at 50 cents per cubic yard is included as measured below the top of the paving brick.

Cost of Brick Pavement Per Square Yard Since 1900.

Size of Brick.	Foundation.	Minimum.	Maximum.
5 in.	Natural sand	$1.18	$1.56
5 in.	8-in. sand or gravel	1.40	1.97
5 in.	6-in. concrete	1.94	2.48
4 in.	6-in. concrete	1.71	2.34
4 in.	4-in. concrete	1.47	1.73

Investigation has shown that the prices paid for the various combinations seem to rise and fall in the same years, which would indicate that the variations depended upon the material and labor market and not on the difference in combination.

The earlier of the brick pavements consisted of small blocks of fireclay 4 in. in depth, laid upon a natural sand foundation. Some of these are still in use though in service on residence streets for 20 years. In other localities, partly on account of traffic conditions, brick pavements on sand foundations required relaying in less than 15 years.

No pavements of brick laid according to recent specifications and practice, nor any laid on concrete foundations, have been in existence long enough to cause any thought of re-laying.

In reference to the brick pavements that now require relaying having reached a condition where any adequate repair would prove far too expensive, it could probably be shown that other defects, such as improper filler, poor brick, or defective construction, had as great an influence in causing deterioration as did the sand foundation. An entirely different condition would probably be found in an open and poorly drained clay district.

In considering the relative economy of sand and concrete foundations for brick pavements experience will show that a properly laid pavement of 5-in. brick on a sand foundation will have a life of at least 15 years, if laid in residence or light business traffic streets. A 4-in. brick under similar conditions would probably have a life of three or four years less.

The problem is to compare the cost of such a pavement with one laid on a concrete foundation the actual life of which has not yet been determined by experience.

The following prices are the average for the last three years and therefore expressive of existing conditions:

5-in. brick, natural sand foundation, $1.27 per sq. yd.
5-in. brick, 8-in. sand or gravel found., $1.58 per sq. yd.
4-in. brick, 4-in. concrete foundation, $1.60 per sq. yd.

Assuming a 15-year life for the 5-in. brick pavement on a natural sand foundation, and the interest to be paid as 4 per cent., it will require a payment of 9 per cent. per year to pay interest on the cost of paving and to provide a fund for its renewal at the end of 15 years. This means an annual payment of 9 per cent. of $1.27 or $0.1143.

In order to compare this with the case of a 4-in. brick pavement laid upon 4 in. of concrete, the same annual payment of $0.1143 must be assumed. Deducting 4 per cent. of $1.60, the cost of such a pavement, for the interest charge, or $0.064, leaves $0.0503 to be applied per year for amortization. This amounts to a little over 3 per cent., and according to amortization tables would require a period of 22 years to provide the renewal fund.

In other words, the pavement upon the concrete must have a life of 22 years in order to be as cheap as the one upon the natural sand having a life of 15 years.

Comparing the cost of the 5-in. brick upon a ballast of 8 in. of sand or gravel with the brick upon 4 in. of concrete, it is readily seen that the difference is so small that both could have the same life at the same cost per year. Evidently then, the concrete foundation is as cheap as the other, and much more economical, as the probability of longer life is much greater.

A 4-in. brick laid upon a natural sand foundation would cost about $1.07 per square yard, using the same cost data as used for the 5-in. brick. If such a pavement had a life of 12 years, with money at 4 per cent., it would require an annual payment of about 11 per cent., or $0.1177.

Comparing this with 4-in. brick on 4 in. of concrete, one sees that the latter would be equally cheap per year if the life of the pavement were about 21 years. It can likewise be shown that the 5-in. brick would be as cheap as the 4-in. if the life of the former were 3 years longer.

Similar calculations will show that a 4-in. brick laid on 6 in. of concrete will be as cheap as 4 or 5-in. brick on the 8-in. sand ballast if its life is 18 years.

From this method of reasoning it may be concluded that where a natural sandy foundation under good conditions is found it will probably be as economical to lay a brick pavement without a concrete foundation as with one, and the first cost will be considerably less. In other locations, however, where it is necessary to bring upon the work from elsewhere the sand or gravel ballast, the first cost will be nearly as great, and the pavement with the concrete foundation will ultimately prove to be the more economical of the two investments.

Several other matters must, moreover, be given consideration when passing judgment on the question. In Ohio, for instance, the municipality though paying only a relatively small proportion of the cost of the initial pavement, namely, the part laid in street intersections and 2 per cent. of the remaining part, must pay 50 per cent. of the expense of relaying any pavement. It is, therefore, decidedly to the advantage of the municipality that a pavement should be so laid that its life will be as long as possible, so that the repairing expense shall come only at long intervals.

An unyielding sub-base, such as concrete affords, is highly desirable, and should be supplied wherever possible, and in most cases will prove more satisfactory even at slightly greater cost. Concrete will carry the pavement load over the many soft places caused by street openings prior to paving and will prove a greater factor of safety against settlements and irregularities liable to occur where no concrete is employed. Any settlement in a pavement foundation breaks the bond of the brick and will be rapidly followed by serious deterioration.

Another possible economy in supplying a concrete foundation may be found in the possibility that some time it may be desired to replace brick with other kinds of paving material for which a concrete foundation must be supplied, such as wood block, asphalt or asphaltic concrete, in which event the cost will be materially lessened by reason of the existing concrete.

In open country, with poor drainage facilities, there is no doubt that the damaging effect of frost and the yielding subsoil would soon depreciate any brick pavement with only a natural soil foundation, and under such conditions concrete is the only safe and economical foundation to use.

RAILWAY TERMINALS.

The subject of railway terminals is one that comes up constantly, with its increasing complexity due to the rapid growth of traffic on Canadian railways. Passenger terminals are of more immediate interest to the general public than freight terminals, and have therefore received much more attention. Yet the freight traffic on most American railways yields the greater part of the gross revenue, and arguments for greater attention to it are set forth in a paper by Mr. L. C. Fritch, chief engineer of the Chicago Great Western Railroad, presented January 14, before the Canadian Railway Club at Montreal. These notes are taken from the paper.

The cost complete of the New Grand Central Terminal in New York City will probably be $200,000,000, a sum that would build 2,000 miles of double track road at $100,000 per mile. This terminal will serve but two railroads, the New York, Central & Hudson River and the New York, New Haven & Hartford. The new Pennsylvania terminal in the same city, serving only the Pennsylvania and the Long Island Railroads, is estimated to have cost to December 31, 1910, $113,000,000. In each case the annual fixed charges, taxes and depreciation, figured at 10 per cent. of the initial cost, plus a much smaller sum for operation and maintenance, will amount to nearly half the annual gross passenger receipts at these terminals of the railroads concerned.

Similar figures may be presented for the Chicago & North Western passenger terminal in Chicago and for the terminal under construction at Kansas City, Mo. Some of the roads which will use the latter terminal will pay more for the privilege than their entire passenger receipts derived from Kansas City. The combined value of passenger terminals used by he Pennsylvania in New York, Philadelphia, Baltimore and Washington is $178,000,000. This is an average of about $800,000 per mile of road from New York to Washington, and the fixed charges alone will average $40,000 per mile.

The annual passenger revenue on all railways in the United States is about $750,000,000. The freight revenue is about $2,000,000,000, or nearly three times as much. Yet so much attention has been given to passenger terminals that only limited appropriations have been made for freight terminals, and their possibilities in the way of economies have been developed to a limited extent only. Existing facilities are in many localities grossly inadequate to handle the rapidly growing traffic with the necessary promptness, and there must be almost a revolution in such cities as Chicago in the methods so long in vogue.

PLANT INSTALLED AT THE LONDON PAPER MILLS AT DARTFORD, ENGLAND.

The plant consists of:—

1. Receiving hopper with supports placed outside the boiler-house on the bank of the river, in such a position that the coal can be deposited into the hopper by a crane and grab.

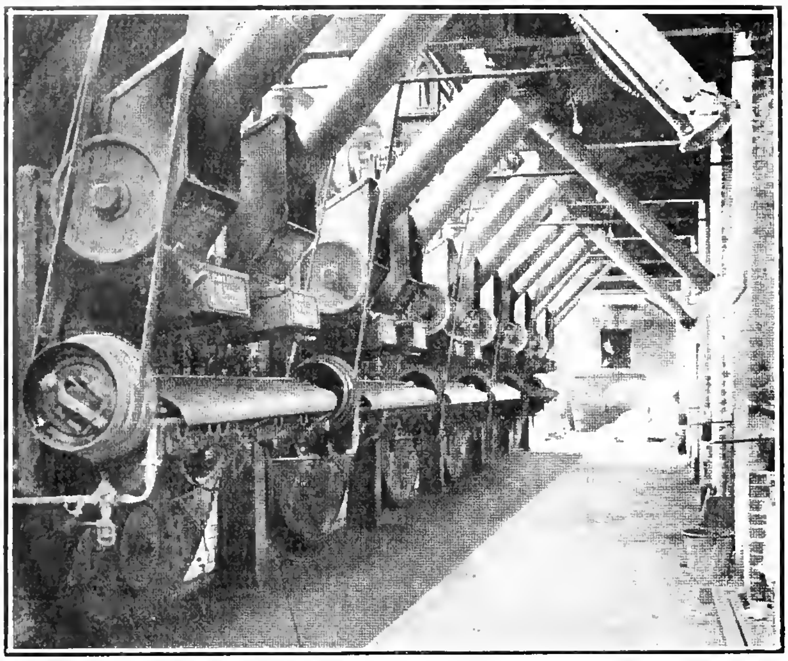


Fig. I.

A range of "Bennis" High Temperature Machine Coking Stokers keeping steam in the boiler-house of the London Paper Mills.

2. Overhead coal storage bunker having a capacity of about 330 tons of coal.

3. Bennis U-link chain conveyors with driving gear and all supports.

4. Shoots to carry the fuel from the bunkers to the hoppers of the Bennis mechanical coking stokers by which the boilers are fired.

The method of operating the plant is as follows:—The coal is brought up to the wharf in barges. A grab load of coal is raised from the barge by the crane, and dumped into the receiving hopper from which it flows through an outlet into the chain conveyor, which is placed immediately beneath. The first portion of this chain conveyor is carried up an incline and the coal is thus raised to the level of the top of the bunkers. The conveyor then passes horizontally over the top of the bunkers, and the coal is dropped through openings into the storage bunkers beneath.

The coal flows by gravity from the storage bunkers into the storage hopper, and a valve is placed at the end of each shoot to control the supply of coal.

The conveyor is of the well-known U-link chain type. It has a capacity of 40 tons per hour, and is driven through suitable reduction gear by a separate motor. The overhead coal storage bunkers are built over the firing floor and are about 80'-0" long x 11'-0" wide having a total capacity of about 330 tons. The boiler-house wall is utilized for one side of the bunkers, the other side consists of a reinforced brickwork wall. The bottoms of the bunkers are hoppered in shape, and are formed out of rolled steel plates with suitable stiffeners and connections.

A number of rolled steel joists run the whole length of the bunker to form supports and carry the weight between the stanchions. These longitudinal joists are supported in their turn by other transverse joists spanning the firing floor and carried at one end on substantial stanchions, resting on the floor, the other end being built into the wall of the boiler-house. These stanchions are also used for supporting one side of the main boiler-house roof, and a light roof is built over the top of the bunkers themselves.

Access is given to the conveyor chamber over the bunkers by ladders and gangways, arranged so that all running parts are easy of access for inspection and lubrication.

The bunker was designed to take full advantage of the existing buildings and to give the required storage without forming any obstruction to the movements of the boiler attendant. It is so arranged that future extensions can be easily effected.

The work of the U-link chain conveyors is to feed the coal to the bunkers which deliver it by means of openings into the distributing shoots which deposit it in the "Bennis" high temperature smokeless and gritless coking stokers. The illustration affords a good view of this range of stokers with the shoots in position and in close connection with the bunkers immediately above.

It is, of course, important that steam-raising in paper mills should be smokeless and gritless. Harm will be done to both paper and pulp in various stages of their manufacture should grits and smuts be emitted from the chimney and so find their way into the incomplete manufactures.

The plant was designed and installed by Edward Bennis and Company, Limited, who are represented in Canada by Geo. H. Tod, of Toronto.

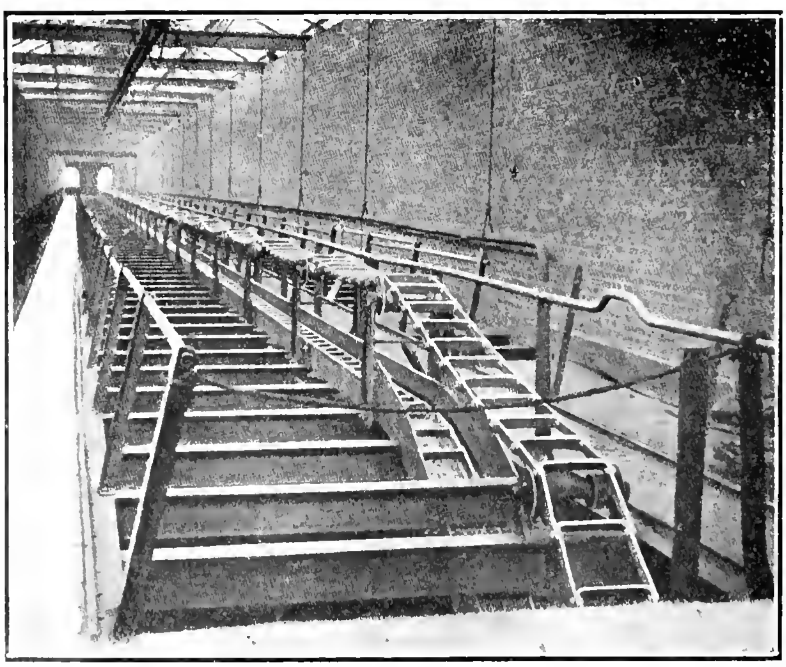

Fig. II.

"Bennis" U-link Chain Conveyor which in part of its travel is inclined to carry the coal to the level of the top of the bunkers. It deposits its contents by means of openings into the storage bunkers beneath. It forms part of the "Bennis" installation of coal handling plant in the boiler-house of the London Paper Mills.

REINFORCED CONCRETE IN CHURCHES.

By V. J. Elmont, C.E., A.M.Can.Soc.C.E.

The essential requirements that one must meet in designing churches and similar buildings are that they should be absolute fireproof and have proper acoustic quali-

Fig. 1.

ties; these requirements are best met by reinforced concrete. In respect of this latter it is interesting to note that organs have actually been built of reinforced concrete in the United States.

Its ability to resist fire has been tested over and over again. Numerous fires in actual buildings have shown that concrete is practically impervious to fire. Also the various technical laboratories have proved how slowly heat penetrates concrete and the fitness of reinforced concrete structures to resist high temperatures. The worst that the ordinarily severe fire will do is to cause a crumbling of concrete on surfaces exposed to the heat, rarely to a depth of more than one inch. Both on this and on the other side of the ocean a great number of test buildings have been constructed entirely in reinforced concrete in order to determine the varying importance of the intensity and duration of the heat applied, its method of application, and the thickness of protective covering.

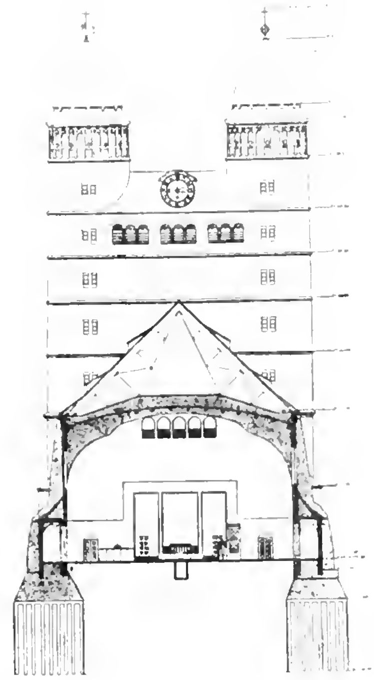

Fig. 3.

As seen from an engineer's point of view, reinforced concrete solves in the easiest and most economical way the difficult problems of construction that constantly occur in the class of buildings we are considering. Reinforced concrete renders it possible also for the architect to design with a free hand and only to take the artistic requirements into consideration. Where steel is used many complications arise through the use of complex construction and also much time is lost and cost entailed in carrying out such work, not to mention the expenses for the covering of such steel with a fireproof material.

The elementary forms which go to make the skeleton usually found in churches, are floors, columns, cantilevers, arches, roofs often with very long spans, consoles, and domes. As an expert in the proper use of adopting reinforced concrete to church building might be mentioned Professor Fisher, in Munich. He has not only used this material in the construction of the skeleton of the new garrison church in Ulm, but given it equal prominence with natural masonry and brickwork, and it appears visible in the elevations; this is one of the first examples we have of this material being used in such a way in large European buildings of an ecclesiastical type. The aforementioned architect obtains without any great expense in this church a span

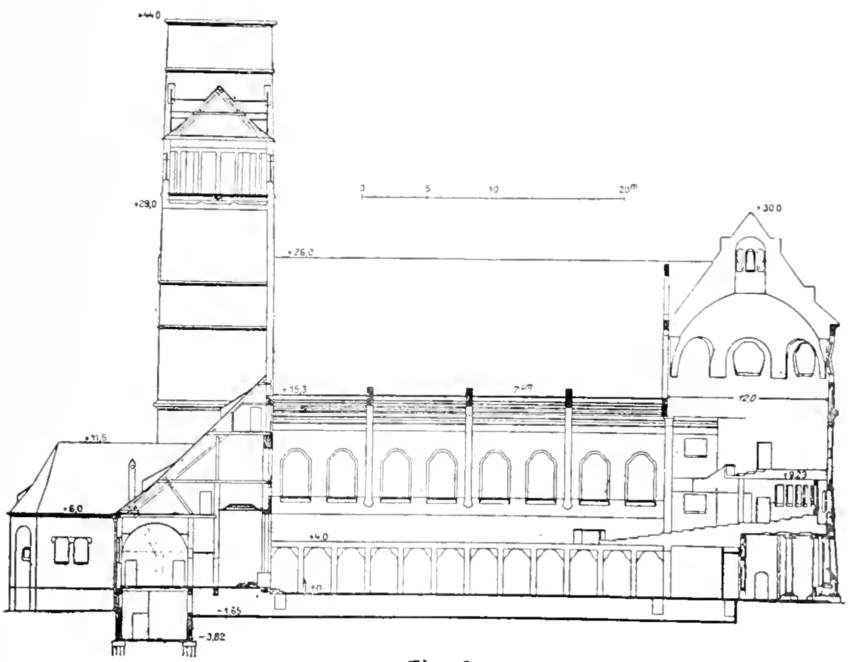

Fig. 2.

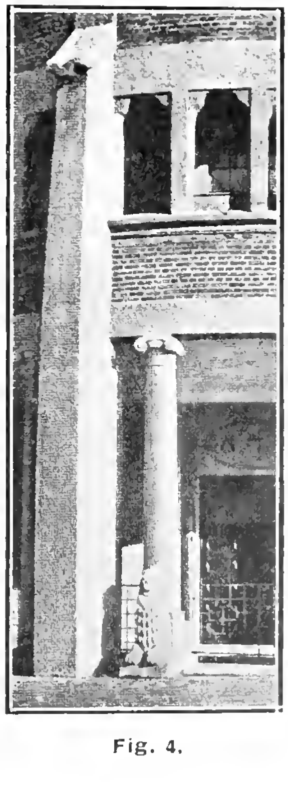

Fig. 4.

which has never been exceeded in any other church of solid masonry. In our medieval cathedrals there are very few spans above 50 feet; the renaissance builders were the first as opposed to the gothic to strive after an effect of spacious-

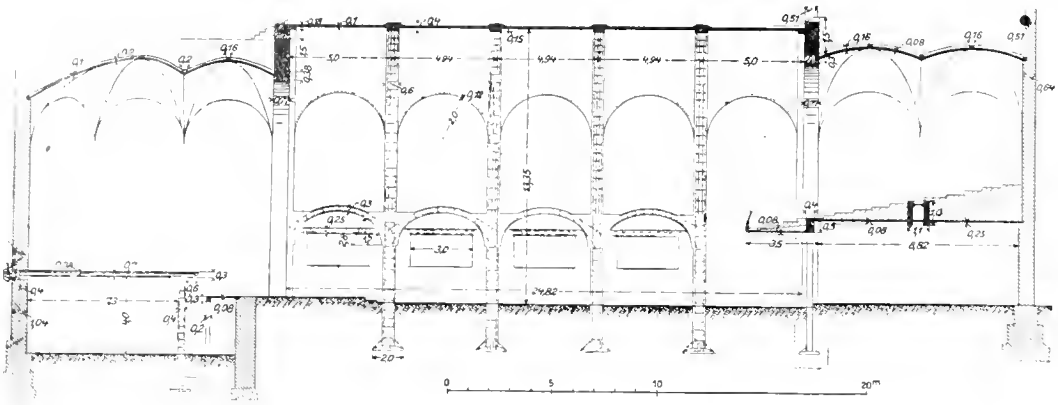

Fig. 5.

ness, which was obtained by enlarging the main dimensions. In the Cathedral of Florence a span of 56 feet was obtained and at St. Peter's, in Rome, the maximum 75 feet was reached. Considering the cost and time which only some few decades ago were necessary to solve similar problems, it will be at once seen how reinforced concrete has accelerated architectural progress.

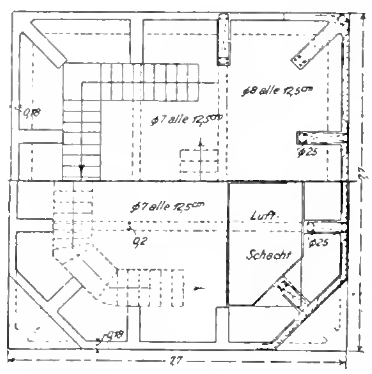

Fig. 7.

Fig. 1 shows the exterior of the church with the concrete parts easily recognizable in the buttresses and in the organ wing. The church consists of three main parts, the nave proper, the organ wing and the two towers with connecting walls containing classrooms for confirmation and the sacristy. Except the towers, in which only the floors and the main cornice are built in reinforced concrete, all the other supports are of this material. There is not a single cut stone existing in the whole building, the corner "stone" also, which was laid by the King of Wurtemberg, was of concrete. The construction in the organ wing does not differ very much from forms in common use outside the fact that there are some cantilevers carrying the galleries with a free span of 25 feet, a roof with 40 feet span and a dome. The more interesting points of construction are to be found in the nave (Fig. 2). The foundation consists of 35-foot-long concrete piles, each capable of carrying 55,000 pounds. These were tested and found entirely safe for 85,000 pounds. The nave is 75

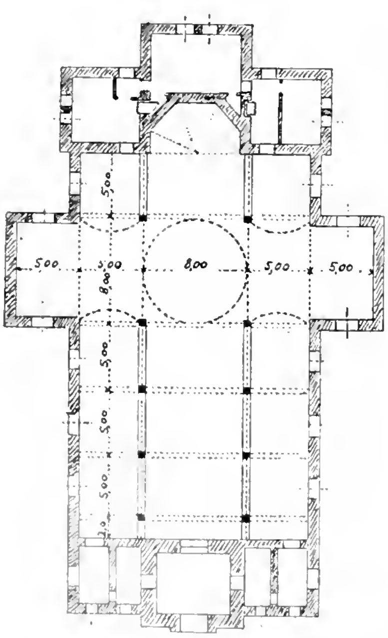

Fig. 9.

feet broad, 100 feet long and 30 feet high and is built up of four enormous girders in arch form. (Fig. 3). Between these spans a slab and beam ceiling forms the vault over the church. The distance between the girders, which are 1½ feet in width, is 25 feet, and in designing these the architect only took the architectural requirements for a good design into consideration, not being bound in any way by the material.

Running lengthways in the side walls of the nave (Fig. 3) are reinforced concrete beams supported by the columns, partly forming the plinth and cornice and partly carrying the brickwork filling which is 12 inches thick.

All concrete surfaces are unplastered, but treated as cut stones and bush hammered. Fig. 4 shows a part of the exterior of the organ wing. The special concrete mixture, used in the exterior, consists of 1 cement, 1 sand and 2 gravel of pea size.

By using a special mixture and afterwards washing and

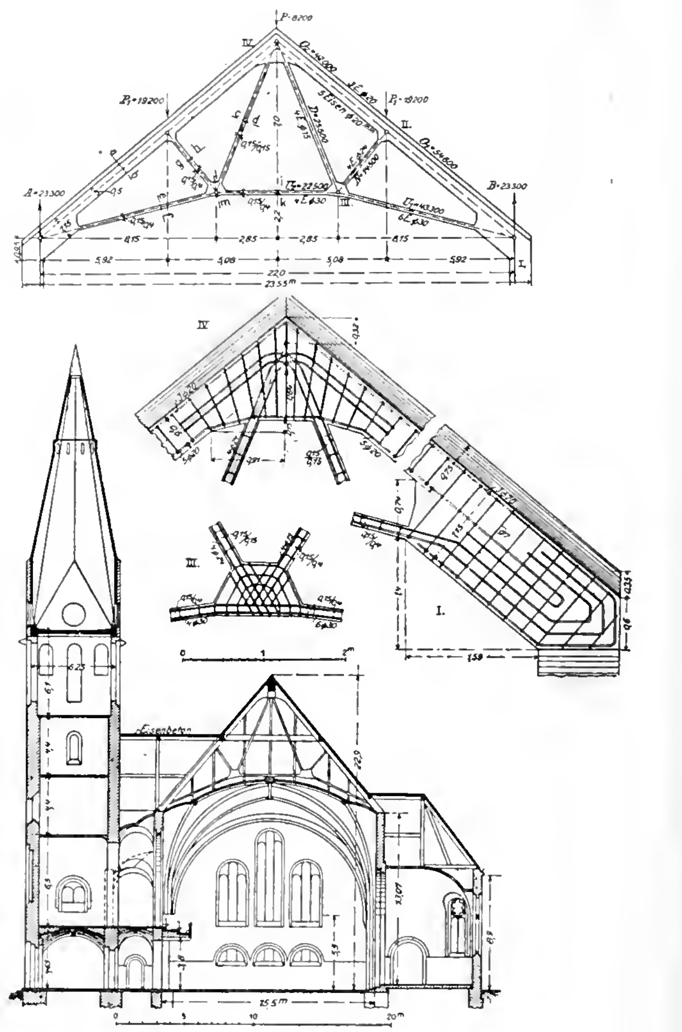

Fig. 8.

brushing it, a surface more natural to the properties of the concrete would be obtained.

For relieving the monotonous grey concrete surfaces inside the church the architect has inlaid small colored (white, black, green and blue) tiles into the soffits of the arches and

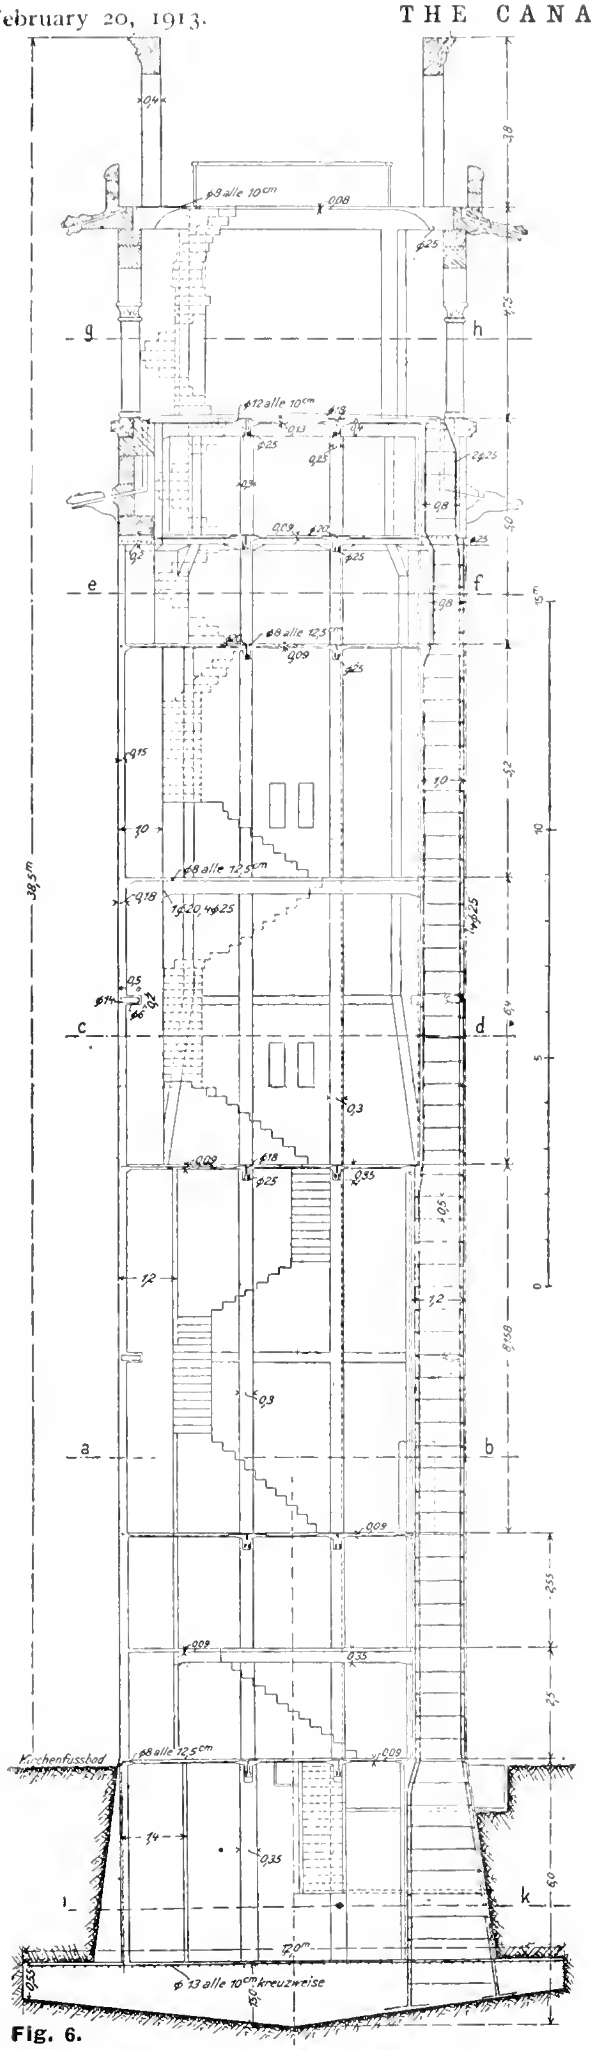

Fig. 6.

the beams. The placing of these hard-burnt glazed tiles [in] the concrete has produced a very good effect; such a ceramic embellishment may perhaps be developed further and in other positions, also to good effect.

In the Markus church, in Stuttgart, the nave is also built up of reinforced concrete arch girders. It is 80 feet long, 50

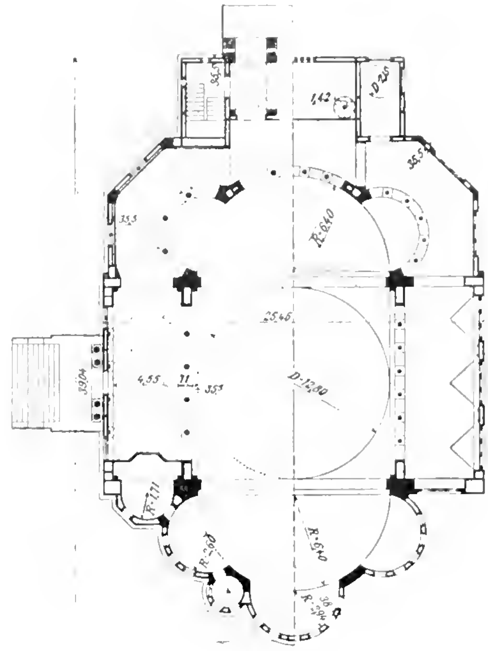

Fig. 10.

feet broad and 45 feet high. Attached to it are two side naves 9 feet broad and 15 feet high. The arch over the main nave consists of the said arch girders, spaced 16 feet centre to centre (Fig. 5) connected by a 4-inch-thick concrete slab. As the architect only permitted 6 inches of the girders to be visible under the slab the rest of the thickness was was placed over the slab. Downward, the arch girders go over into the columns, in which the beams and columns for the side

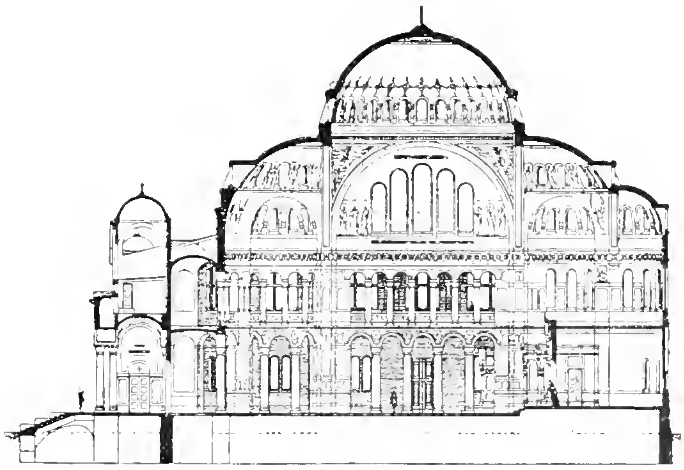

Fig. 11.

naves are also fixed, so that the frame for the three naves forms a monolithic, connected whole, of great strength and stiffness.

An interesting feature in this church is that the 190-foot-high tower is built up in reinforced concrete. After careful examination and deliberation the leading consultants for this church building decided upon the use of this material, apart from any question of economy, being of the opinion that its employment minimized the possibility of cracks arising from

the swinging of the bells to a greater degree than in any other material, and also that it offered the greatest resistance in proportion to its weight, and was capable of resisting tensile as well as compression stresses, and in addition to these advantages was perfectly fireproof.

The tower (Figs. 6 and 7) rests on 12 reinforced concrete columns connected with 8-inch-thick concrete walls; they go

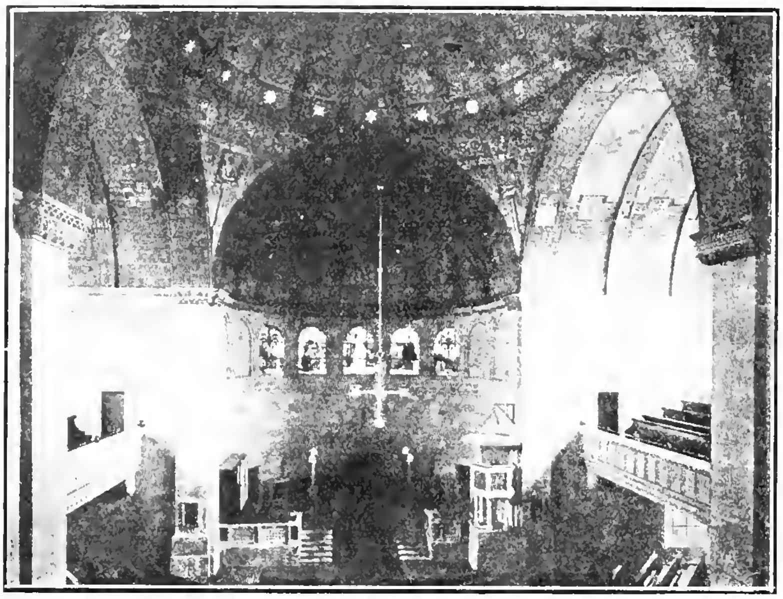

Fig. 12.

along the total height of the tower and are at the base 1 foot by 7 feet, and at the top 1 foot by 2½ feet. They are stiffened laterally by the floors. The foundation slab, 40 feet square, is situated 20 feet under the church floor, from this slab and up to a height of 60 feet the tower is 25 feet by 25 feet. From that elevation the corners are taken off so that it continues as an octagon. In elevation 90 feet above the floor the reinforced concrete walls stop short and are continued in brick. Over the room for the bells are only four columns carrying the last story, 16 feet high.

The bells are hung up in a special manner (Kurz system) which causes the tongue of the bell to meet the clapper when it is inclined at about 45 degrees to the vertical, and both are swinging outwards as opposed to many other systems, in which the tongue meets the clapper during the backward swing, thus causing greater impact stresses in the tower. After the Kurz system church bells have been built up to 13,000 lbs. weight, and are capable of being rung by only two men.

In the garrison church in Kiel the roof, the top of the tower and the gallery pews are constructed in reinforced concrete. The roof (Fig. 8) is supported by two diagonal Polonceau trusses of 75-foot span, built entirely of concrete and reinforced with thin bars. The tower top, placed upon the 85-foot-high brick tower, has 4-inch-thick walls, is 21 feet square at the base and 65 feet high.

In Russia reinforced concrete has already been in use for over 10 years in church buildings, not only in the greater cities but even in the villages, where one would think that the very low temperature during the long winter, the difficulty of transport and of getting the necessary able labors would throw insuperable obstacles in the way. This view (Fig. 9) shows the typical plan of such a village church and with the interior entirely built up in reinforced concrete. The roof slab is supported by concrete beams with 26-foot span between the columns and 16 feet between the brick walls and columns. Not only in those churches roofed by arches but also in those roofed by domes a great number are to be found in which reinforced concrete is employed.

One of the most interesting and characteristic examples is the church in the Russian city, Poti, situated in the swampy delta territory between the Black Sea and the Caspian.

As at the outset the cost prohibited the carrying of the foundation 70 feet deep through shifty sand down to firm ground, the chief consideration was to reduce the weight of the walls and domes to a minimum. Of the schemes sent in, the reinforced concrete one was selected, which not only met these requirements, but was the cheapest and also the most expeditious in spite of the fact that the work had to be performed by unskilled local labor. The walls are only 14 inches thick, including a 7-inch-thick airspace. The main piers, in accordance with the architect's desire for massive exterior, are built hollow (Fig. 10) containing pipes for heating and ventilation. The roof is formed of one main dome (Fig. 11) with 42-foot span and attached to this are two half-domes and to one of these again smaller half-domes.

A dome of similar size is built in reinforced concrete in Christ Church in Dusseldorf (Fig. 12). This dome is supported by four arch girders of 45-foot span, and over these four parabolic arches are arranged, carrying the weight of the tower.

The dome in Los Angeles, with its 62-foot span, (described in the February 6th, 1913, issue of The Canadian Engineer) is still one of the largest church domes built in reinforced concrete, but in other classes of buildings this width has in many cases been surpassed. For instance, the span of the dome shown in Fig. 13 is nearly 100 feet, and at the present time one with 200 feet span is under construction.

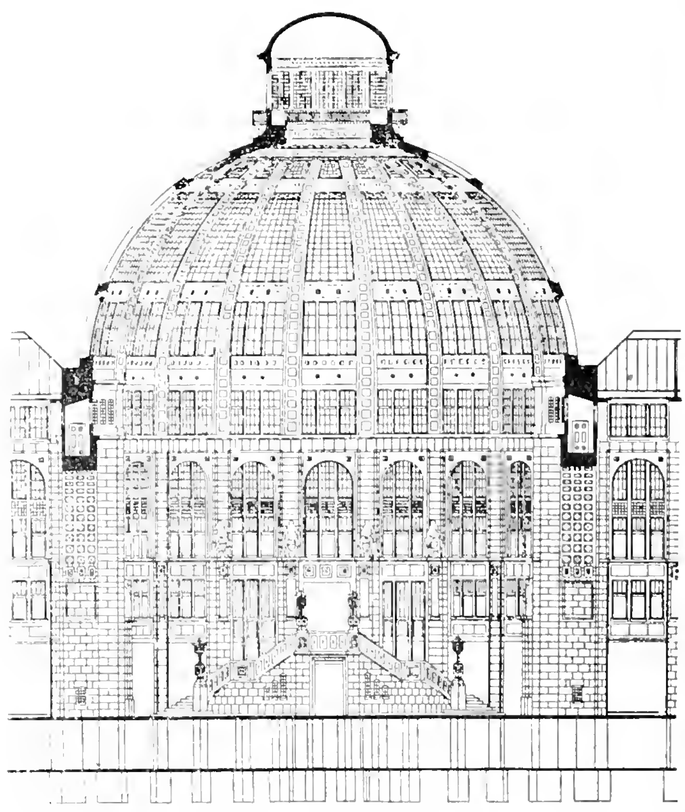

Fig. 13.

A LARGE REINFORCED CONCRETE STANDPIPE.

The details of the design of the 300,000-gallon reinforced concrete standpipe which was recently constructed in the town of Penetanguishene, Ontario, are shown herewith in Fig. 1. This tank is described in a recent issue of Engineering and Contracting. As will be noted from the drawings, the tank is 50 ft. in diameter and 21 ft. deep. The side walls are of 1:1:2 concrete, 12 ins. thick at the base and 8 ins. thick at the top. The walls are made thicker than necessary for strength in order to prevent the formation of a thick ice crust. The tank is covered by a reinforced concrete dome of a height of 1/10 of the diameter. It is 4 ins. thick and is reinforced by ⅜-in. bars 12-in. on centres.

The tank was built in about six weeks during October and the early portion of November of 1912. It was filled the latter part of December, and did not show a leak or sweating at the first filling nor thereafter.

The reinforcement of the shell was figured by a method not ordinarily used in the United States. If we consider a a shell alone and assume that it is not connected with the bottom, it will increase in size as shown by curve A of Fig. 2. Inasmuch as the shell is connected with the bottom, and besides rests on the ground, it cannot elongate at the bottom, and if a proper connection is made between the side walls and bottom, the lowest portion of the shell cannot even change its directions at the bottom; or, in other words, it is fixed at the bottom. Hence, the real deformation of the shell will be a line somewhere as shown by curve B in Fig. 2. It clearly depends on the thickness and height of the shell where the deviation from the ideal line of deformation stops.

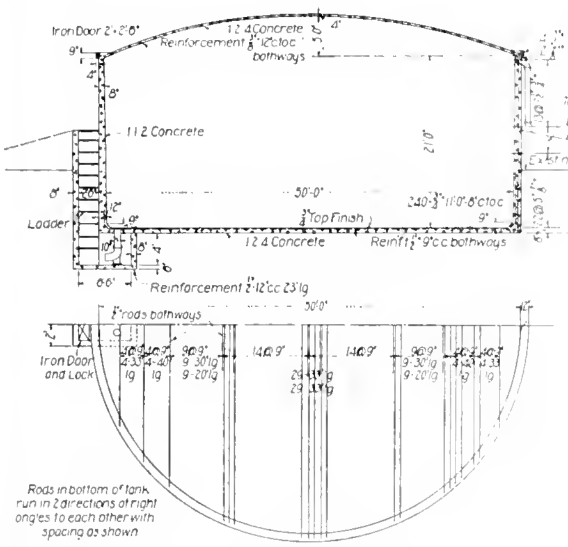

Fig. 1.—Details of Design of New 300,000-Gallon Reinforced Concrete Standpipe for Penetanguishene, Ontario, Waterworks.

This problem was first investigated by Professor Grashof, and published in his book on "Theory of Elasticity" in 1878. The differential equations governing the conditions are, however, of a high order, and even in the simplest case where the walls are of uniform thickness, the equations for the elastic curve are expressed in periodical functions and it takes several days' labor to solve a single problem. The equation cannot be solved for walls of various thicknesses, as the integrals of the differential equations are unknown up to this day. However, the elastic equations clearly show that the shape of the elastic curve is a function of $\frac{h^2}{rt}$, wherein h is the height of the tank, r the radius of the tank, and t the thickness of the shell at the base, all being expressed, of course, in the same unit.

In the present case $\frac{h^2}{rt}$ equals 16 and the elastic curve for this case only starts to deviate abruptly from the ideal deformation at the point of 4/10 h above the base, as shown in Fig. 2, curve B. This means that the water pressure corresponding to the shaded portions is not taken up by the ring action but by the cantilever action of the connection of base and shell. After a little consideration, it will be clear that there must be acting on the ideal beam, for this case a force above the 4/10 h point, which tends to bend it back into the

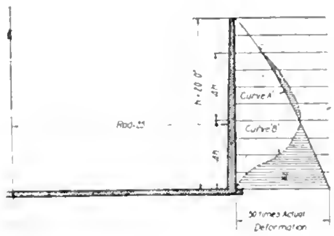

Fig. 2. Deformation Diagram.

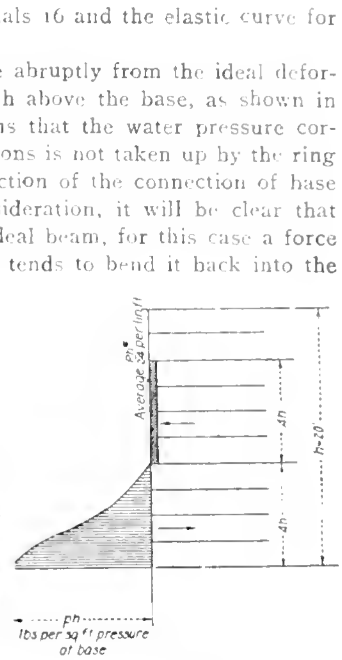

Fig. 3. Loading on Ideal Beam.

line formed by the ideal deformation of the ring sections, as the cantilever would tend to bend the top portion further out and the deformation on top must be zero from the nature of the case. This force is nearly a uniform load also for a height of 4/10 h in this case and equals approximately $\frac{ph}{24}$ in this case. Now, if a beam is assumed which is acted upon by the forces as shown in Fig. 3, we can find the elastic curve from the equation $\frac{d^2y}{dx^2} = -\frac{M}{EI}$, wherein M is the moment at any section x feet from the top, E the modulus of elasticity and I the moment of inertia at the section x. If the assumption of the form and position of curve B of Fig. 2 is correct, the elastic curve obtained by the foregoing general equation must be identical with curve B. This agreement can be reached after a few trials.

It is also clear that there exists beside the negative moment at the bottom of the shell on the inside, a positive moment higher up on the outside of the shell. The maximum value of this positive moment occurs where the shear passes through the zero value. The shear at the bottom of the shell can also be obtained from Fig. 3. This shearing stress governs the reinforcing of the bottom of the tank. The moment at the bottom of the shell, in this case is about

$$\frac{ph^3}{66} = \frac{62.5 \times 20^3}{66} = 7{,}600 \text{ ft.-lbs. per lin. ft.}$$

The reinforcing here adopted is more than ample. The positive moment on the outside of the shell is $\frac{ph^3}{217}$, which can be taken up by the concrete without reinforcing. If the reinforcement at the bottom of the shell be omitted, the tank will first crack on the inside of the shell at the junction with the bottom, and then a larger bending moment will appear on the outside of the tank $= \frac{ph^3}{163}$ in this case. This

bending moment is already large enough to cause cracking of the concrete at the surface of separation between the portions placed on different days.

For other values of $\frac{h^2}{rt}$ the shape of the elastic curve is, of course, different from that here shown as curve B of Fig. 2. The greater the value of $\frac{h^2}{rt}$ the lower the point where the curve deviates from the ideal deformation of the ring sections.

The standpipe here described was designed and built by L. J. Mensch, M.Am.Soc.C.E., of Chicago.

STREET AND RAILWAY TRACK PAVING WITH ASPHALT BLOCK IN A SUBURBAN TOWN.*

By Frank Chappell, Town Engineer, Oshawa, Ont.

It is possible that few Ontario towns have labored under more adverse conditions to secure a permanent pavement than has been the case with the town of Oshawa. It is certain that but few towns had greater need of pavement. Oshawa is a thriving manufacturing town, 34 miles east of Toronto and within four miles of Lake Ontario. The centre of the town lies in a hollow in what is said was formerly a cedar swamp. While excavating for a catch basin, a row of logs side by side—a relic of an old corduroy road—was found, six feet below the surface of the present street. This fact alone would suggest the difficult nature of the soil to be contended with.

Then again, the street railway company in Oshawa, operate under a Dominion Government Charter granted them about seventeen years ago. By reason of the looseness of agreements and by-laws drawn up between them and the town at that time, the street railway company are not obliged to pave between their tracks or pay any proportion of the cost of such paving. This refusal of the company to recognize any obligation or necessity on their part of paving their right of way, was the greatest stumbling block. Special legislation was at last secured, however, permitting the corporation to finance the whole work as a local improvement, the railway company agreeing to relay its track to conform to the new grade established, and further agreeing to pay a portion (amounting to only about 65 per cent.), of the extra cost incurred in placing concrete under the ties. This percentage, moreover, was to be made payable over a period of 20 years. It might be well to state here that railway companies, making overtures to pass over the streets of Oshawa now, are not allowed to slip easily through, but on the contrary have to face and commit themselves to the most binding legal documents it is possible to execute.

The selection of a pavement had again and again been discussed. One year the cheapness of construction of Macadam road proved an attraction, but after a short strip had been constructed upon one of the main residential streets, it was found to be so dusty in summer and so muddy in the spring and fall of the year as to preclude its usefullness in the business portion of the town. The desirability of a plain concrete pavement was then discussed, mainly because of its reported cheapness. The poor economy of these cheap ideas are the biggest drawbacks to communities in the transitory stage from village to town, and from town to city. While the concrete pavement in this instance would have been an interesting experiment, it was, however, voted down by the people immediately concerned.

The asphalt block pavement upon a concrete base was finally chosen after the mature deliberation of all parties. A sheet asphalt pavement is beyond the reach of a small town because of the expensive plant necessary at all times to handle the construction or repairs which might be required. Each asphalt block, however, may be regarded as an asphalt pavement in miniature, its composition and manufacture approaching to a considerable extent that of sheet asphalt. When well laid, the blocks, while possessing many of the desirable qualities lack one extremely undesirable feature of sheet asphalt, namely local creeping.

The streets to be paved in Oshawa, were the two main thoroughfares, which intersect each other at right angles in the centre of the town. The street railway track lies along both streets. In order that the contractors might have every facility for carrying their work to a successful issue, the work was divided into four blocks or sections, and all adjacent street intersections were closed to traffic while any particular section was being constructed. In each case the work was started at the extreme end of a section and progress was made towards the centre—known locally as the four corners.

The traffic was thus but little inconvenienced, for while the last portion was being completed in the centre, the other streets and intersections were open for traffic. Moreover, by closing the street against traffic of any kind, it was possible to make a more satisfactory job of the track work, as well as giving the road a greater period for setting and seasoning before use. The first step taken in construction was to make all sewer, water and gas connections, even vacant lots being connected. The whole of this work was well filled in and soaked down with water.

Grade stakes were set out on each side of the street and driven to the proposed elevation of top of curb. This was also the new elevation of each rail. In the meantime the track was completely dismantled, and the old ties hauled away, while the rails and angle bars were thrown on the boulevard. Excavation was proceeded with to a sub-grade eight inches below the finished surface of the pavement. In the centre, corresponding with the street railway allowance a shallow trench, 9 ft. 6 ins. wide, was excavated eighteen inches below the finished surface. This would allow eight inches of concrete to be deposited below the ties, and about one foot beyond the ends.

Concrete in the specified proportions of one to nine, but actually nearer one to seven (an alteration necessary on account of the grading of the gravel), was placed in this trench to a depth of six inches. Within twenty-four hours the ties were laid on this and after the rails had been spiked and jointed, were brought to grade with wooden shims, about three or four to the rail. This left a two inch space to be filled with concrete. Great care had of necessity to be observed, in order to pack the concrete under the ties, and a very wet concrete was used, entirely free from large stones. This was done as it was believed that the ties would be more securely bedded in the concrete than if the whole eight inches had been filled at once. Furthermore the track was more easily and accurately brought to grade with this two inches of play.

The method of laying the ties and rails and subsequently raising to grade on the first six inch layer of concrete is avoided by contractors because of traversing the work twice with concrete mixers, etc. In over a mile of similar work done later this method was insisted upon, however, by the writer, and is still believed to be a far better plan than to lay the concrete all at once. The rails and ties if graded up to their

*Paper presented to the Canadian Society of Civil Engineers, February 6, 1913.

proper position are so easily disturbed by gravel teams, wheel barrows, etc., while a much longer period is necessary for the setting of such a thickness of concrete—longer than is permissible in street paving work. The second application of concrete was made at the same time that the base was being laid for both sides of the road. The curbs were also prepared at the same time, the base and sides thus being practically monolithic.

As far as track construction is concerned it is not pretended for one moment that the work described in this paper is by any means ideal. As noted in the preamble, the corporation was largely at the mercy of the railway company, which refused to admit any obligation. So when the company insisted on using old 56-lb. T. rails, 4" deep, which had been in constant use for nearly twenty years, the only thing to be done was to make the best of such unfavorable material. New ties were provided of Norway pine, but the old angle bars were used. This in particular was a point to which the writer was strongly opposed. For such rails, the writer recommended that the ends of the old rails be cut off and that they be redrilled.

Moreover, a continuous bar joint was to be used. The reason for this was, that in using the old rails and old bars after they had been once dismantled, different bars would probably be connecting other joints. Now these bars during their long service, some 15 to 20 years, would have acquired a "set" in some direction, and this could certainly not be taken out by merely tightening the bolts in re-jointing. However, this was over-ruled by the company, and the only pieces of track replaced with new material were a few split rails and defective switches. The fallacy of expecting a miscellaneous collection of angle bars to fit an equally miscellaneous quantity of defective rails was amply proven in less than six months after the work was completed.

The concrete base was well laid and is an excellent piece of work. It is possible now, however, in less than a year, to stand on a rail joint and cause a perceptible vibration with one's foot. The effect can be imagined, therefore, of street cars hammering on such joints. Even the railroad authorities now admit the poor economy shown in such parsimonious construction, and later work has been done with heavier rails having newly cut ends and new bars, although the continuous bar-joint which the writer believes is absolutely necessary in street railway work is still kept out, only, however, on the score of extra expense. The ties were laid at two foot centres with additional ties thrust under the joints. With the second layer of concrete, the ties became perfectly embedded at the ends, sides, and over the top.

The whole base was now ready for block laying and this took place usually within about three days of the concrete base being laid. A slightly dampened mixture of cement and sand in the proportions of 1 to 3 was distributed over the concrete surface to a uniform thickness of one-half an inch. Between the rails allowance was made so that a crown of half an inch could be given the blocks. The blocks were laid upon this cushion of cement and sand, and then rolled with a heavy hand roller of from three to four tons weight. The surface was then minutely inspected for any imperfectly bedded blocks, which were at once removed with specially shaped tongs, and a small portion of cement cushion placed so that the block would not rock. The blocks were laid between the rails in the same line as the rail. Now this is a nice looking piece of construction and it also has the advantage of being very easy to lay, and furthermore the number of "bats," or broken blocks, is considerably reduced.

The writer has noticed, however, that where cars have been derailed, the tendency is to open up the unbroken course for a considerable distance, should the car wheel strike the longitudinal joint. It is a question that [illegible] well to note, as to whether any greater advantage is gained over this method by the more expensive work of cutting and fitting blocks within the track, at right angles to the line of traffic.

The fact that the blocks were laid in the same line as the rail is another regrettable instance of the overruling of the professional man by the lay man. Two and one-half inch blocks are too small for railroad work in the first place. The street car wheels abrade a place for themselves assisted by external traffic to a depth of about one and one-half inches. This then leaves but one inch of block to resist any lateral pressure which may be brought to bear by vehicles crossing a street diagonally. The result is that a block becomes loosened when laid in the same line as the rail by reason of the open surface offered by its longer side. As soon as one block is thrown out it is less difficult to loosen others. If the blocks had been laid in this instance as specified, at right angles to the rail, there would have been at least greater holding surface.

After all blocks had been rolled, examined and found to "bed" properly, the surface was sprayed with water from a fine nozzle. A cement grout was then prepared in equal proportions of cement and sand. This was poured over the blocks and brushed well into all joints and interstices. As this grout dried out it settled until the joints were only about three parts full. A second application of a stronger grout was then applied, two parts cement to one part sand, and this mixture was brushed into the joints until they were packed full. As the rails in the track were T rails, a space about two inches wide was left on the inside of each rail to be worked into a groove for the flanges of the car wheels.

A concrete of crushed granite and cement was packed well into this space and shaped with a tool to the required width and depth. This has proven a very satisfactory piece of work and while undoubtedly cheaper, it is in the opinion of the writer, under certain conditions even to be preferred to scoria blocks and granite "setts." The car wheels crush and abrade the concrete and the edges of the blocks to an extent necessary for clearance and after a little wear, a smooth uniform groove is made. The blocks are soft enough to yield to the abrading action of the car wheels without loosening the joints, while the little inequalities in the concrete groove are subject to direct crushing.

With reference to the concrete groove between the blocks and the rail, this too would probably have shown to greater advantage had a thicker block been used, say 3" or 4". This, of course, was not possible on account of the 4" rail in use. There is this about the concrete groove, however, that when abrasion occurs the dust that is produced washes away and the groove has that much less material. To overcome this the writer has since tried on over a mile of road, a groove filler of a mixture of bitumen and broken stone. This is almost a ductile composition and it is possible that, in warm weather, at any rate, the bituminous mass will accommodate itself to the groove, and give better results than similarly placed cement.

In connection with turnouts and switches, the triangular space facing the frog gave considerable difficulty. Blocks were in the first place cut and fitted and grouted in. The space was so narrow, however, that the wheels would push them out of place. Concrete of the same consistency as the groove was next tried, being one part cement, one part sand and three parts crushed granite. This, in some instances, lasted no longer than the blocks, while even where car traffic was infrequent, although the life was much longer the result was not satisfactory. A plate of hard grey cast iron, called by the author, a "frog piece," was at last substituted and drilled and spiked to the ties with the countersunk

spikes. The blocks were paved up to this and the whole cemented in.

This cast iron frog piece is, as far as the writer knows, entirely original and has proven a distinct success. Neither the castings or the adjacent blocks have moved in the least, and this method was adopted at seven different turnouts. Three turnouts were left without such provision and blocks, concrete, etc., were tried out, but without success. These will now be fitted with cast iron plates. The pavement, except for the street railway work, has shown up very satisfactory so far. The blocks appear to be uniform and there are no inequalities in the pavement, the only trouble being with the before-mentioned blocks in the track allowance.

The diamond used in the centre of the town is of an altogether too light and flimsy nature. It consists simply of rails four inches in depth, bolted together on plates at the corners and with cross braces in the centre. This should at least have been made of heavier rails of the "girder" type, although there are cast steel diamonds made which have given great satisfaction, and are undoubtedly to be preferred. The result of using the poor diamond above described has been to loosen all the blocks inside and the blocks for a distance of about four feet outside the rails. Repairs are being made on this work at the time of writing.

All headers at street intersections were made of granite concrete, as for curb, and extended twelve inches beyond and to the full depth of the pavement base. This has proven very satisfactory, although the writer believes that it should be carried further—say two feet beyond the pavement, where the intersecting street is unpaved.

The following data may be of interest:—

Price of gravel, deposited on work by teams at contract price	$1.00 cu. yd.
Price of cement deposited in shacks	1.52 barrel
Superficial prices:—	
Excavation and grading	17 sq. yd.
Concrete base (5″)	53 sq. yd.
Blocklaying and ½″ cushion	22 sq. yd.
Blocks—teamed on to the work (freight Windsor to Oshawa inclusive)	1.57 sq. yd.
Cubic yard prices for work under track:—	
Excavation	50 cu. yd.
Concrete base	4.68 cu. yd.
Curb and gutter	56 lin. ft.
Average cost of catch basins	24.00 each
Total cost per lineal ft. of 40 ft. road	14.84
" " " " 35 " "	12.98
" " " " 30 " "	11.12

These measurements are taken from face to face of curb.

This last table of total costs includes paving the street, laying curb and gutter, paving the track allowance, extra concrete under the ties, the dismantling and relaying of the track, together with all catch-basins, etc., required.

The total yardage of the pavement was 14,300 sq. yds., and the total cost including the foregoing incidentals was $47,750.00.

GRAND TRUNK EQUIPMENT ORDERS.

Orders have been placed by the Grand Trunk system for locomotives as follows for the coming year: 25 Mikado type from the American Locomotive Works, Schenectady, N.Y.; 50 Pacific type from the Baldwin Locomotive Works, Philadelphia, and 15 large standard switching engines from the Canadian Locomotive Works at Kingston. The Mikado locomotives are larger than any locomotives now in use in Canada. Ten Pacific engines have also been ordered from the Montreal Locomotive Works.

RAILWAY FINANCING LAST YEAR

During the past ten years Canada has experienced a wonderful era of expansion in railway building, which has had a marked influence on the development of the country from shore to shore. Probably in no other country have such determined efforts been made to provide transportation facilities, and the rapid rise in importance of Western Canada is an eloquent tribute to this far-sighted and courageous policy. The total railway issues for 1912, according to Mr. E. R. Wood's bond review, were $69,972,320, almost the same as the aggregate for 1910, but falling considerably below the record of 1911—$100,472,700.

Of the railway bond issues, $61,382,320, or 87.73 per cent., found a market in Great Britain, while Canada took .21 per cent., and the United States 12.06 per cent. Great Britain continues to finance the greater part of our railway development. These issues and the markets in which they were sold are set forth in the following table:—

RAILWAY ISSUES.

Company.	Amount.	United. States.	Great Britain.
Canadian Pacific Railway 4% Consolidated Debenture Stock	$10,962,320	....	$10,962,320
Grand Trunk Railway 4% Perpetual Consolidated Debenture Stock	12,500,000	....	12,500,000
Grand Trunk Railway Equipment Trust Notes, Series "A"	3,940,000	$3,440,000	500,000
Grand Trunk Railway Equipment Trust Notes, Series "B"	3,360,000	3,000,000	360,000
Canadian Northern Railway 4% Perpetual Consolidated Debenture Stock	6,960,000	....	6,960,000
Canadian Northern Railway 5% Income Charge Convertible Debenture Stock	10,000,000	....	10,000,000
Canadian Northern Railway Equipment Trust Notes, Series "C 1"	2,000,000	2,000,000	....
Canadian Northern Railway Equipment Trust Notes, Series "D 1"	3,000,000	3,000,000	....
Canadian Northern Railway Equipment Trust Notes, Series "E 1"	2,000,000	1,850,000	....
Canadian Northern Pacific Railway 4% Debenture Stock (guaranteed by British Columbia)	5,000,000	....	5,000,000
St. John and Quebec Railway 4% Stock (guaranteed by New Brunswick)	4,250,000	....	4,250,000
Edmonton, Dunvegan and British Columbia Railway 4% Debenture Stock (guaranteed by Alberta)	3,500,000	....	3,500,000
Algoma Central Terminals Limited 5% Bonds (guaranteed by Lake Superior Corporation)	2,500,000	....	2,500,000
	$69,972,320	$8,440,000	$61,382,320

CONTENTS OF THIS ISSUE.

THE SUGGESTED CHANGES IN THE ONTARIO RAILWAY AND MUNICIPAL BOARD ACT.

The powers of the Ontario Railway and Municipal Board will be considerably enlarged if the proposed Ontario Railway Act, now before the Provincial Legislature, is enacted.

A clause which will have far-reaching effects, is that dealing with the right of the Board to order the construction of spur lines or branches upon the application of an industry. This clause, if adopted, will give the Board power, where any industry lying within six miles of a railway desires shipping facilities and cannot agree with the railway company as to construction and operation of a spur, to order the railway to construct and operate such a line. It may also direct the applicant to deposit in a chartered bank a sum sufficient to construct and complete the spur, and this amount can be paid by the Board to the railway from time to time as the work proceeds.

The aggregate amount so paid by the applicant in the construction and completion of the spur line shall be repaid or refunded to him by the company by way of rebate to be fixed by the Board, out of the tolls charged by the railway company upon the traffic over the branch.

Until the total amount of the cost of construction is repaid, the applicant retains a special lien for this amount on the line; when payment has been received by the applicant, the railway then receives total ownership of the spur.

The old section of the Act, which this clause replaces, entails very roundabout methods, and operates by means of the submission of a by-law. The Board has no mandatory powers under the present Act to enable it to see that its wishes are carried out. This change, if adopted, will be instrumental in securing quicker action, and should work to the advantage of both the railway and the applicant.

Another important change is that providing that a general preliminary plan of a new railway must be filed before the Board. These plans must show the location of the line, the towns through which it passes, the rivers or other railways covered or within a radius of thirty miles. The Board is given the power to approve these plans and to alter them if deemed necessary.

GOOD ROADS.

History repeats itself. The world is again assuming the Roman attitude toward good roads problems. Neither technical education nor country residence is required to appreciate the value of good roads. Any town or village unfortunate enough to be off the railroad map is off every map unless good roads link it up with the world.

Yet it is surprising how many city bred men still believe good roads to be a useless expense—that is, until they buy their automobiles. And even a few farmers can be found here and there who are narrow-minded enough to begrudge a road tax. Educating the public to enthusiasm about good roads has naturally been a slow process, and there have been but few men in Canada who have had the patience and public spirit to keep at the educative task.

Among those whose efforts have not been in vain and who have done a great amount of very praiseworthy work without any hope of personal reward, have been the executive and members of the Ontario Good Roads Association. Special interest is aroused in the annual

meeting of this Association at Toronto next week owing to the co-operation which is being accorded to them so liberally at the present time by the Ontario Government. It is understood that the government has practically pledged itself to spend several millions, beginning early in 1914, upon good roads in the more settled parts of the Province. The Ministers are said to look with favor upon the Toronto to Hamilton, Ottawa to Prescott and Toronto to Montreal roads, and the construction of these much-needed highways at a comparatively early date is practically assured.

Had the Ontario Good Roads Association never done any other work, it has fully justified its existence by its splendid promotion and organization work in connection with these three roads. Some of the members of the Association have spent hundreds of dollars personally and given weeks of time to the work without any remuneration whatever. Their main task now seems to be securing Federal co-operation. It is to be hoped that some plan will be brought out at the Convention next week which will result in interesting the Dominion government to a greater extent than the Association has succeeded in doing in the past. With Federal aid the county councils should be able to afford any type of pavement which will be the best and cheapest ultimately, regardless of a possible higher first cost.

CANADA CREOSOTING COMPANY.

Forty acres of land on the river front at Trenton, Ont., have been purchased by the Canada Creosoting Company, which will erect a large plant for creosoting timber of all kinds.

The United States Wood Preserving Company and the American Creosoting Company jointly control the stock of the Canada Creosoting Company, but about one-third of the shareholders of the Canadian company will be residents of Canada, as a block of the stock of the new company is being sold privately in Canada. The head sales office of the new company will be at Montreal, where a tank station will be erected. Creosoting oils will be brought to the Montreal station in tank steamers from Europe. A small tank steamer, specially constructed for going through the St. Lawrence canals, will carry the oil from the Montreal station to the Trenton plant. Mr. E. S. Clements, of the United States Wood Preserving Company will be the Canadian manager, with headquarters at Montreal. President Hurt, of the American Creosoting Co., will be the president of the Canadian company. A. B. Clements, vice-president and general manager of the United States Wood Preserving Company, will be the vice-president.

The company will treat, principally, railroad ties and wood paving blocks, by the vacuum-pressure method. Approximately 150 men will be employed at the start. A plant costing in the neighborhood of $200,000, and with storage space for a million ties, will be erected at once. The company has purchased enough ground to be able to treble the initial capacity of the Trenton plant, and it is thought that within a year the capital of the Canadian company may be greatly increased and the plant considerably enlarged.

The Trenton plant will be practically a duplicate of the United States Wood Preserving Company's Toledo (Ohio) plant, which is said to be the most modern and best-equipped wood preserving plant in the United States. Three cylinders, each 190 feet in length, will be constructed at once for the creosoting process.

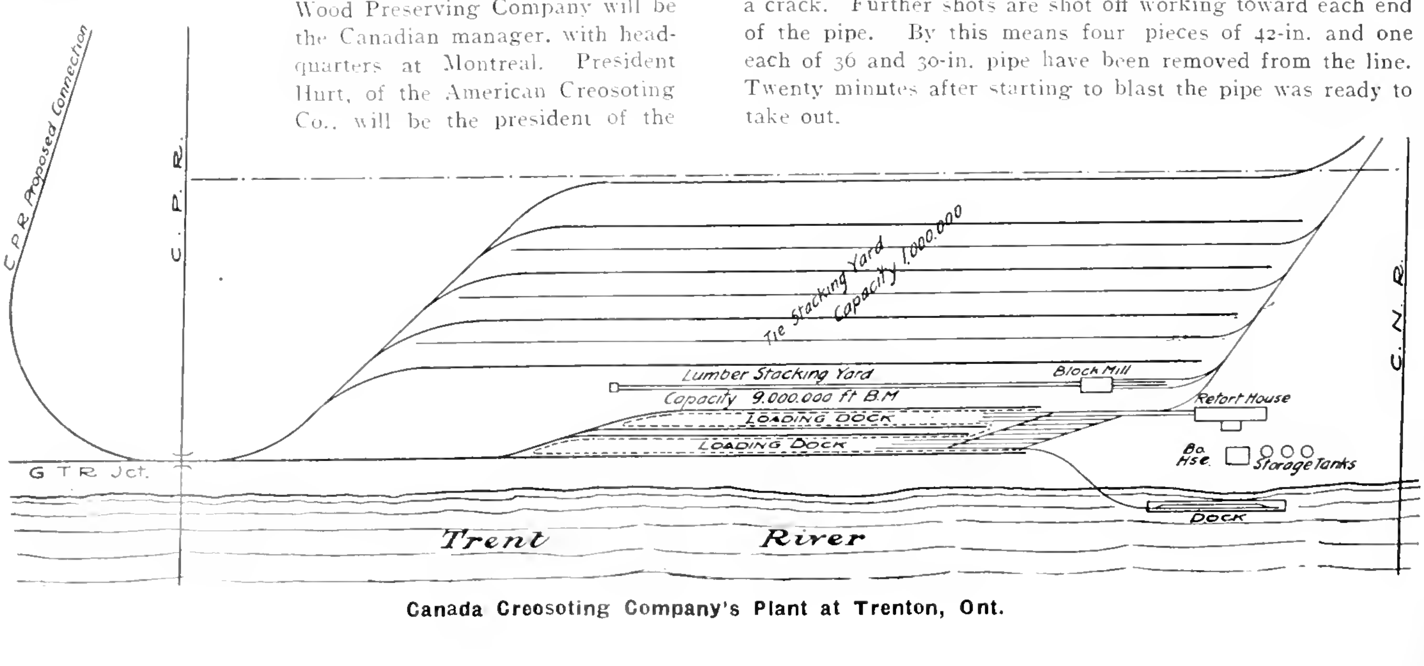
There are already two big plants in Canada engaged in preserving timber—those of the Dominion Tar & Chemical Company, Limited, at Transcona, near Winnipeg, and at Sydney, N.S. The Dominion Tar & Chemical Company produce their own creosoting oils at tar-distilling plants at Sault Ste. Marie, Ontario, and Sydney, N.S. It is not expected, however, that the Canada Creosoting Company will in any way conflict with the business of the Dominion Tar & Chemical Company, as there will undoubtedly be a tremendous call in the next decade in Canada for preservative treatments of timber, and the plants of both companies will probably be worked at full capacity.

The railroads save huge sums by having their ties creosoted, as it adds but little to their cost in comparison to the many years which it adds to the lifetime of the ties. Bridge timbers, piling, sheeting, shop and factory floors and wood for many other purposes can be very profitably creosoted

DYNAMITE FOR REMOVING BROKEN SECTIONS OF CAST IRON PIPE.

At the annual convention of the American Water Works Association, Mr. W. F. Wilcox described the use of dynamite for removing broken sections of large size cast iron pipe.

The method utilized is as follows: Starting in the centre of the pipe to be removed, place ¼ to ⅓ of a stick of 40 to 60 per cent. dynamite on top of the main and cover it with a handful of clay. The blast blows out a small hole or starts a crack. Further shots are shot off working toward each end of the pipe. By this means four pieces of 42-in. and one each of 36 and 30-in. pipe have been removed from the line. Twenty minutes after starting to blast the pipe was ready to take out.



Canada Creosoting Company's Plant at Trenton, Ont.

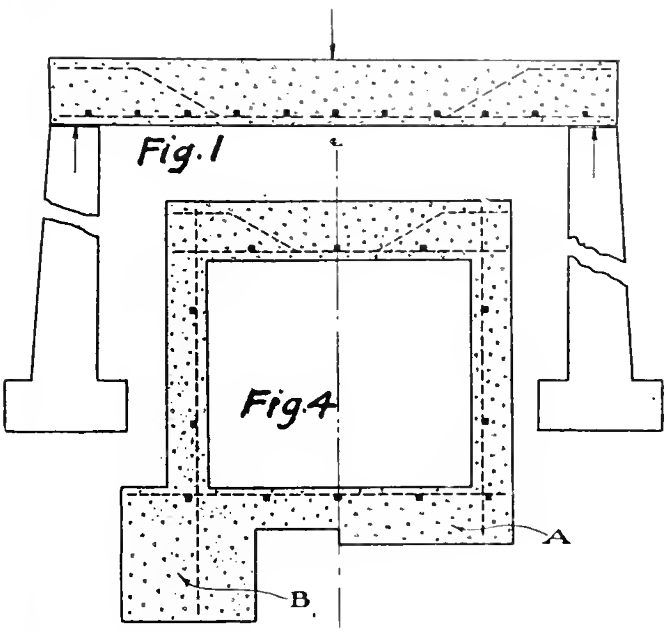
CONCRETE BRIDGES AND CULVERTS*.

In view of the fact that so many of the concrete highway bridges constructed in the last few years are composed of various combinations of simple beams and cantilevers, it may not be out of place before taking up the study of these various types to briefly summarize the laws governing the action of simple beams and cantilevers.

Figure 1 shows a simple slab or beam supported at the ends and loaded as indicated by the arrows. Under the action of the three forces as indicated, namely, the two abutment reactions and the load, the beam tends to deflect or bend at the centre, producing a crack or cracks extending from the bottom of the beam upward. The reinforcement is placed perpendicular to these cracks to carry the tension and thus prevent cracking of the concrete.

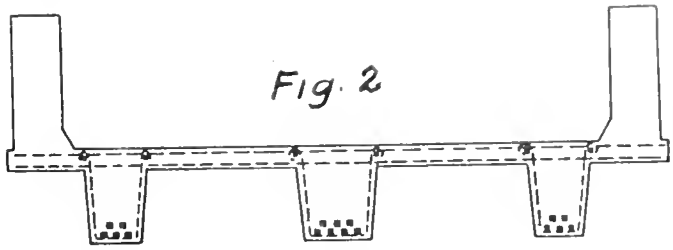
In the preceding case no account was taken of the shearing forces existing in the beam. Without going into the technical details, let it suffice to say that these shearing forces so modify the direct tension that, in addition to the tendency to crack at the centre, there is also a tendency toward the formation of cracks running diagonally upwards and toward the centre between the quarter point and the end of the beam. This is the so-called diagonal tension or shearing crack. Two methods of reinforcing are used to counteract this cracking tendency. In the first one, a portion of the reinforcing members at the bottom of the beam are bent up, running through the concrete at an angle varying from 30 to 45 degrees to the top of the beam and thence horizontally to the end, as shown in Figure 1.

In the second system, vertical stirrups, consisting of a series of vertical rods fastened to the main horizontal reinforcing members, and running up through the beam carry the shear. (This last arrangement is shown in Figure 2, which is a cross sectional view). Since the tendency to crack



is greater towards the ends of the girder than at the centre, the number of stirrups is increased approaching the ends. The method of reinforcing which is used and recommended by the commission consists of a combination of these two methods, using both the bent up rods and stirrups.

Figure No. 3 is a cross section through the body of a reinforced concrete abutment. The darkened portion above the abutment represents the superstructure which re[illegible] the abutment. If an expansion joint between this abutment and the superstructure is constructed to permit free movement between them, the action of the earth pressure has a tendency to produce cracks extending from the back of the abutment toward the face and should be reinforced as shown in this sketch by vertical bars placed near the back face (marked A). Should the expansion joint prove defective, the pressure of the earth under this condition produces a bulging action of the abutment and the necessity for reinforcing steel on the front face is at once apparent.



The various types of concrete highway bridges constructed in this state, adapt themselves to the following classifications:—

Circular and box culverts.
Slab bridges.
Girder bridges and arches.

The girder bridges may be sub-divided into the deck and the through types. In addition, there is the steel truss with concrete floors and abutments.

Taking them up in the order named, Figure No. 4 is of the box culvert type, showing the cross section through the barrel of the culvert. The top, sides and floor of this culvert act as beams under the vertical loads, the horizontal earth pressure, and the upward foundation pressure respectively. Since in each case the load acts from the outside inward, the reinforcing is placed in each case on the inside of the wall or slab. Since there are no expansion joints, no cantilever action can take place and there is no need for reinforcing on the outside of the walls. The top slab is reinforced with bent up bars, as shown, to provide for the diagonal tension as outlined above.

Two types of footings are used in these culverts. The one marked "A," known as a float footing, consists of a heavy floor extending clear across the slab and depending for its stability on the wide distribution of the load. In the type marked "B," the footings directly underneath the walls are carried down to a considerable depth and are connected by a thin floor slab built just strong enough to take the bending due to frost action.

The second type, as the name implies, consists of a slab or beam of concrete (Fig. 1) as wide as is required for the roadway, resting on two abutments. The reinforcing is for simple bending and diagonal tension. Since at each bridge seat there is an expansion joint, the abutments (Fig. 3) are reinforced near both back and front surface with rods running vertically and horizontally. The horizontal rods form a frame-work for the reinforcing, bond the wings to the abutment proper and prevent cracking due to temperature changes in the concrete. The rods in the back face take all the ordinary stress. The front reinforcement is called into action only in case of the failure of the expansion joint to act properly, on this account the vertical reinforcing system in the back is much heavier. Steel bars placed both longitudinally and transversely in the footing, as shown, help to distribute the footing load and to anchor the main reinforcing members.

Fig. 2 is a cross section of a deck girder bridge. The girders are nearly rectangular in section, having a slight

* From a report by Thos. H. MacDonald and C. B. McCullough, of the Iowa Highway Commission.

draw towards the bottom to admit of easy removal of the forms. These girders, or stems, are thoroughly bonded by means of stirrup rods to the floor slab which rests on top of it, the latter acting both as the floor and as a top flange for the girder. The load is carried by the floor to the girders and by the girders directly to the abutments. The rectangular sections at the side of the roadway serve simply as hand rails and do not help to transmit the load.

Due to the diagonal tension, there is always a tendency for the bent up reinforcing members to fail by a pulling out or breaking of the bond near the end. For this reason a positive connection or fastening of the main reinforcing members at the end of the girder is very desirable. A system of this kind employed with success by the commission during the last year is substantially as follows:—

The reinforcing bars are bent in the shops and fitted with a hook on the end. An end plate is also made in the shops and fitted with notches or slits from both top and bottom of sufficient width to admit the reinforcing bars. These notches are so spaced that when the reinforcing bars are dropped in they occupy the position as computed in the structure. After the bars are dropped in these notches, two small plates about 3/8 of an inch thick are bolted one to each side of the plate both top and bottom, thus completely enclosing and rigidly fastening the reinforcing members.

The other type of a girder (the through, Fig. 5) differs from the type just described, in that the girders, two in number, are placed above and at the side of the roadway. The reinforcing in these girders differs very little in principle from that employed on deck girders. The girders now occupy the space occupied by the hand rail in the deck type and the floor system is hung between the two girders and reinforced transversely in much the same manner as an ordinary slab.

In the last type, the arch, the loading comes upon the structure through the fill above it, produces cross bending in the arch ring and a thrust against the abutments. The type of abutment used commonly is known as the gravity type and consists of heavy mass concrete work depending for its stability on its size and weight. The necessity for immovable abutments will be evident from the following consideration. Any spreading or settling of the abutments will be followed by a downward deflection of the arch ring which in turn produces a tendency to crack at the crown on the lower side and at points near the spring line on the upper side. Any slight settlement of the abutments produces a tremendous stress in the arch ring and the necessity for adequate abutments cannot be too greatly emphasized.

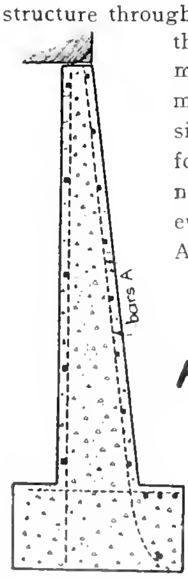


Fig. 3

The circular mold culvert is a combination of the arch and box culvert type and is adapted to small culvert work where an opening not to exceed thirty or thirty-six inches is required.

There is a distinct difference in the shape and size of the drainage lines over this state, those lying within each distinct glacial area being peculiar to that area and the types of waterways built should be selected with reference to the topography. For illustration: In the broad, flat, monotonous stretches of the Wisconsin glacial region which lies in the north central part of the state, the drainage areas are for the most part, flat and not well defined. The channels quickly fill to overflowing and a large percentage of the waterway must be obtained by raising the road grade above the land level.

For such openings, the slab and through girder bridges offer the greatest amount of waterway with the least rise and span. In the construction of bridges in this area, the possibility of the ditch being incorporated in a drainage district must always be guarded against in planning a bridge. An instance is brought to mind of a practically new concrete bridge in Buena Vista county that is to be destroyed because the foundations were not carried sufficiently deep when constructed to provide against the deepening of the channel as part of a drainage district.

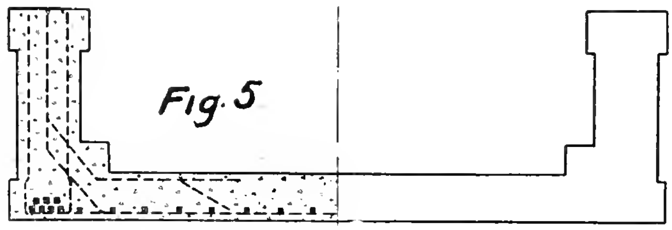

Fig. 5

In the more rolling areas along the rivers on the east and west boundaries of the state, many of the streams have deep, sharply defined channels. During times of heavy storms the water rushes through the openings in mad little torrents that quickly scour under the foundations unless they are protected by deep footings and floors. For these deeper ravines, the box culvert with ample floors and footings, the slab or deck girder or arch bridge with high rise are all applicable. In the Kansas drift area which covers a large portion of the southern part of the state, the deep cut drainage channels generally exist and these types are all applicable to this section.

For spans up to about sixteen feet it probably makes very little difference in the amount of material either of steel or concrete, required to build a culvert of either the above types provided the depth of foundation and area of waterway is the same. For spans sixteen feet and above, the character of the foundation will have much to do with the determination of the economical structure. Yellow or blue clay is about the best foundation (unless piling is used) that can be found in a majority of the counties of the state and one of these can be reached at a depth of three or four feet below the stream bed.

On such foundations the form of construction, such as the slab or girder bridge, or for the longer spans, steel bridges with concrete floors, seems to be desirable as the expansion joint at each abutment will take care of the expansion and contraction of the structure as well as any settlement of the foundation without causing material cracks.

GREAT WATERWAYS UNION.

A general meeting of the Great Waterways Union will take place at Berlin, Ont., at an early date and representatives of the many municipalities interested in the Welland Canal and St. Lawrence River route development are expected to be present. Henry Holgate, of Montreal, has been advocating on the behalf of the union that the government create a Department of Inland Waterways to study and develop inland navigation.

STORM WATER DISCHARGE.

By R. O. Wynne-Roberts* and T. Brockmann.†

(Continued from last week).

Mr. Symons, in 1878, observed a precipitation in Camden Town, London, England, falling at the rate of 12 inches per hour, continuing for 30 seconds (Moore). In the Central States of America a rate of 3.7 inches for 10 minutes, 2.8 inches for 20 minutes, 2.3 inches for 30 minutes and 1.7 inches for 60 minutes may be expected (Folwell).

The following are a few recorded examples of the intensity of rainfall. Those recorded in Toronto were kindly supplied by Prof. Stupart, the director of the meteorological service.

Year.	Place.	Duration of storm in minutes.	Actual rainfall recorded inches.	Rate of rainfall inches per hour.
1905	Ponders End, England..	19	1.05	3.32
1905	Birmingham, England .	27	1.04	2.31
1905	Birmingham, England .	7½	0.56	4.50
1906	Burnham, England	40	1.73	2.60
1906	Guildford, England	8	0.87	6.68
1907	Worcester, England	8	0.43	3.22
1905	Wallington, England ...	65	2.77	2.55
1869-1891	New York, U.S. ...	10	1.20	7.20
1871-1891	Washington, D.C...	5	0.80	9.60

It is unfortunate that there is comparatively little information available as to the intensity of rainfall in different parts of various countries. Still, the records suffice to show that the maximum intensity ordinarily lasts only for a few minutes, sometimes at the commencement of a storm, other times in the middle or at the end of it. Furthermore, the area of maximum intensity is usually circumscribed and often located in different parts of a district.

It often occurs that after a prolonged drought, rainfalls of great intensity are experienced. Sometimes it happens that during long periods of wet weather, when the surface is already saturated and the sewers are flowing practically full, a rainfall of greater intensity will fall and thus give rise to floods—unless the sewers are of more than ordinary capacity.

* Consulting Engineer, Regina.

† Civil Engineer, Regina.

If records of rainfall in wet districts are carefully [illegible]d. [illegible]t will doubtless be found that the intensity is relatively lo[illegible] there in comparison with drier districts.

Figure 1 shows two curves illustrating rainfall intensity. Curve I. represents moderate amounts of rainfall observed at Edgebaston, Birmingham, England. This curve is a copy of one prepared by Mr. Wallington Butt, who stated that it is more or less applicable to other parts of England, and by it storm water discharges can be estimated in that country. Curve II. represents the mean highest rainfalls observed in Germany, and this generally constitutes the maximum intensity assumed in that country.

Both curves serve to show that the intensity of a rainfall varies inversely with the duration of the storm. For example, a rainfall of 20 minutes duration has an equivalent intensity of one cubic foot per second-acre in Birmingham, and 1.73 cubic feet per second-acre in Germany, whilst a ten minutes rainfall has an intensity of 1.33 and 2.36 cubic feet per second-acre respectively.

Although the following diagram (Fig. 1) will be found useful as a graphical method of ascertaining the factor of rainfall intensity with sufficient accuracy, it will doubtless be acknowledged that it is highly desirable to ascertain the intensity in any particular district by means of reliable automatic recording rain gauges, of which the simplest is usually the best.

In countries where a considerable accumulation of snow takes place, such as in Canada, and this melts in spring time, it is a matter of great importance to give this point careful thought, for it often occurs that rain falls when the temperature rises, and this causes serious floods. No statistics are at present available on this feature of our enquiry, so it must be left for the reader to bear it in mind when undertaking investigations.

In addition to ascertaining the rainfall intensity in any district, it is practically certain that it will not be of uniform intensity throughout that area, especially if the area is at all extensive. An interesting example of this is referred to by Sir Maurice Fitzmaurice, who, when discussing Mr. Lloyd Davies' paper, remarked that very heavy showers were extremely local in character, and mentioned a case where rain falling heavily at Hampstead caused a sewer at King's Cross, London, to be gorged and some lives to be lost, although, where the men were working no rain had fallen. The distance between the two places is only about three miles.

Careful observations have been made, in Germany, for instance, and it was found that the mean intensity of rainfall became less as the drainage area increased in size, or the sewers increased in length, beyond a certain radius from the point of heavy rainfall.

It may be stated that observations were made in Breslau, Germany, on an area of about 1,700 acres to ascertain the relative intensity at three stations located as far apart as possible, and it was found that during a period of 760 minutes rain fell simultaneously for only 90 minutes at two stations, and at the three stations for only 28 minutes. In view of these facts, it was not justifiable to assume a uniform intensity over a large area. Further investigations were, therefore, instituted so as to ascertain in what manner the maximum intensity "qr" varied, with the result that it was found that the intensity diminished to "qr/2" in a distance of about 10,000 feet from the point of observation.

It may be objected that it is too unfavorable to base a conclusion on such limited number of instances where rain fell on all three or two stations as the same time, and to ignore the larger number of rainfalls which occurred at solitary stations.

It is submitted, however, that such precaution is justified by the limited extent of the observations, by their local char-

acter, and by the fact that storms are not stationary, but travel in different directions, sometimes across a district, sometimes diagonally and at other times along the major axis of the drainage area, in the latter case a proportionately

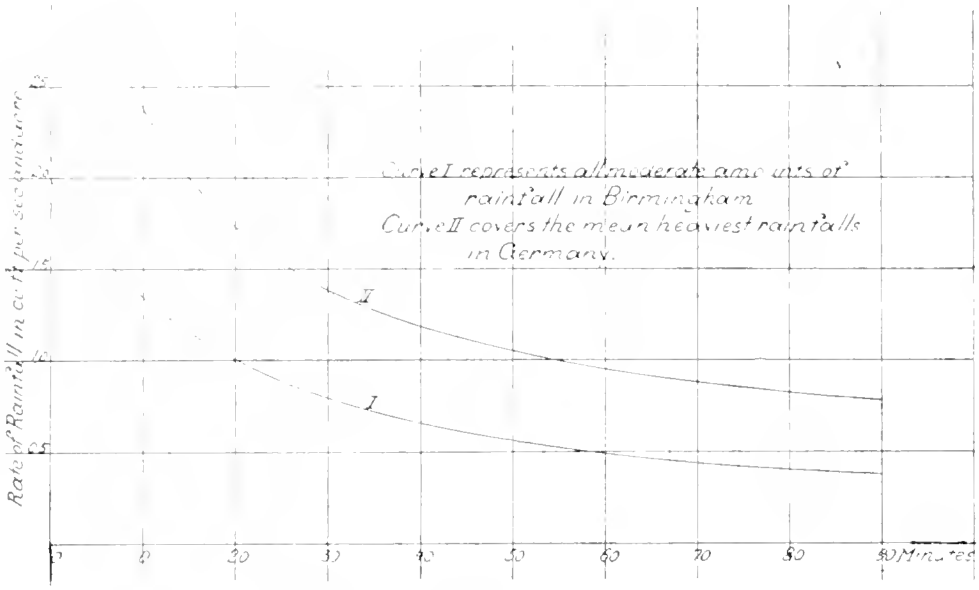

Fig. 1.—Rainfall Intensity Curves.

larger quantity of storm water will naturally have been precipitated and have to be dealt with.

It may also be contended that it would be more accurate to take, instead of the length of 10,000 feet, a value depending directly on the intensity, for as the area decreases, the intensity increases. The results of the observations, however, are not sufficient to ascertain, with any degree of accuracy, the relation which subsists between the intensity of a rainfall and the area and, moreover, those downpours taken into consideration have some features in common in the manner of occurrence, and do not differ very much in their intensity.

For the sake of simplicity, it may be assumed that the curve representing the decrease from the maximum intensity "q_r," to that at the remote part of a district, "q /2," is that of a parabola, so that the intensity and extent of any storm are represented by a solid of revolution, generated by the revolution of a parabola along its axis, and a section along this axis will therefore be, as shown in Figure 2, at M, A, N, O, P, being limited on the top by two parabolas. The ratio between the solid of revolution and a cylinder representing a uniform rainfall, then, will give the coefficient

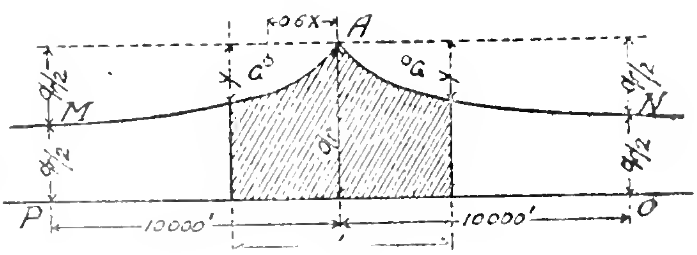

Fig. 2.

"I" by which the highest intensity assumed has to be multiplied so as to obtain the average intensity of storm, and his factor is called the "coefficient of intensity."

Let "A" be the zero point, then the parameter "p" is found from $10{,}000 \times p = \left(\frac{q}{2}\right)^2$ or "p" equals $\frac{q^2}{40{,}000}$; the equation of the parabola will be

$$\text{"}y^2\text{"} = \frac{q^2 \times x}{40{,}000}.$$

The circumference described by the centre of gravity in revolving is $2 \times 0.6\, x \times \overline{x}$, therefore the content of the solid of revolution corresponding to the shaded area (cylinder minus parabola) is

$$x^2 \pi q - \tfrac{2}{3}\, x\, y\ 1.2\, x\, \pi = x^2 \pi (q_1 - 0.8\, y)$$

and

$$\text{"I"} = \frac{x^2 \pi (q_r - 0.8\, y)}{x^2 \pi q_r} = 1 - 0.8\,\frac{y}{q_r}.$$

As $\frac{y}{q_r} = \sqrt{\frac{x}{40{,}000}}$, "I" $= 1 - \frac{0.8\sqrt{x}}{\sqrt{40{,}000}}$.

The downpour will yield the maximum storm if "A" is located in the centre of the drainage area, and then "x" may be assumed to be equal to one-half of the length of the sewer and it will be:—

$$I = 1 - .0028\sqrt{L}$$

"L" is the length of the sewer in feet.

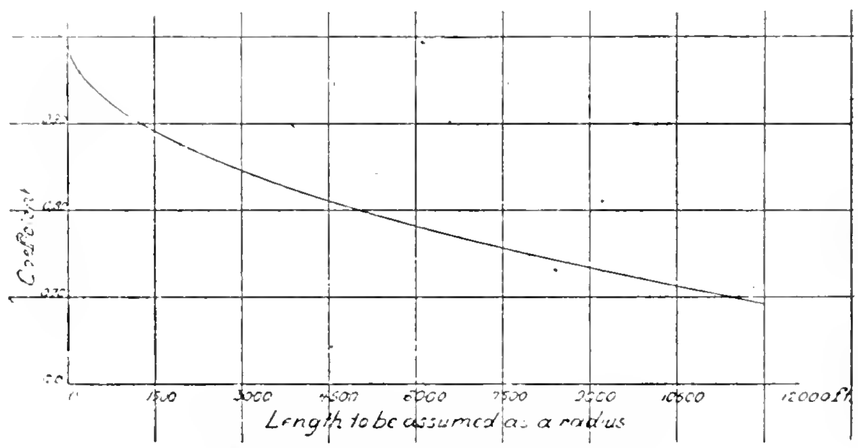

Fig. 3.—Diagram for Determining the Coefficient of Intensity.

If "q_r" be taken equal to "y" then from the equation of the parabola, the values "x" equals 40,000 feet and "L" equal to 2x equal to 80,000 feet will be obtained. This, therefore, is the limit of the application of the above equation and obviously this limit will accordingly not be attained even in the case of very extended sewerage system.

The following table will give the coefficients of intensity ascertained by means of the foregoing formula $I = 1 - 0.002\sqrt{L}$:

L in feet.	Coefficiency of intensity.	L in feet.	Coefficiency of intensity.
500	.937	5,000	.802
750	.923	5,500	.793
1,100	.9115	6,000	.782
1,250	.900	7,000	.766
1,500	.892	7,500	.758
1,750	.883	8,000	.750
2,000	.875	9,000	.733

L in feet.	Coefficiency of intensity.	L in feet.	Coefficiency of intensity.
2,500	.860	10,000	.720
3,000	.847	12,000	.692
3,500	.835	15,000	.660
4,000	.823	20,000	.605
4,500	.813		

Figure 3 has been prepared to give the above information.

As an explanation of the foregoing table and diagram, it may be stated that if the calculations in connection with a proposed sewerage system is based upon a high rainfall intensity of, say, 1.428 cubic feet per second-acre, the sewer being, say, 1,650 feet long, the coefficient for which in the above table and diagram is 0.89. Then 1.428 × 0.89 equals 1.271 cubic feet per second-acre, which is the intensity to be provided for when designing the sewers.

It will be observed that it is necessary in this connection to reduce the rainfall, which is measured in inches depth, to cubic feet per second-acre. As one inch of rain per hour on one acre is practically equal to one cubic foot per second-acre, it will be a simple matter to make the conversion. Thus

1 inch of rain per hour equals 1 cu. ft. per second-acre
0.5 inch of rain per hour equals 0.5 cu. ft. per second-acre
0.1 inch of rain per hour equals 0.1 cu. ft. per second-acre
and so on.

(To be continued).

JANUARY PRECIPITATION.

Precipitation was deficient from Eastern Saskatchewan to the Highlands of Ontario, throughout the Maritime Provinces, with the exception of the vicinity of Halifax, and also over the southern part of Vancouver Island. Elsewhere the amount recorded exceeded the average. The snowfall in British Columbia was phenomenal, especially in the Coast districts. At Vancouver nearly five feet of snow fell during the month and sleighing was general for three weeks.

A considerable quantity of snow fell in British Columbia during the month, and at its close sleighing was good in most localities, the depth in southern districts being about eight inches and in the north, five feet. In Southern Alberta the snow covering slightly exceeded one inch, but elsewhere in the Western Provinces the depth was generally more than six inches, and reached twenty-five in northern parts of Manitoba. Much less snow than usual was on the ground from Ontario eastwards, there being about thirty inches in northern districts which decreased as southern localities were approached, where in Ontario and the Maritime Provinces the ground was bare of snow.

The following table, included in the report of the Meteorological Office, Toronto, shows the total precipitation of fourteen stations for January, 1913:

FACTS AND FANCIES ABOUT SEWAGE DISPOSAL.*

By Gilbert Thomson, M.A., F.R.S.E., M.Inst.C.E.

The number of methods of dealing with sewage has been enormous. They may be broadly grouped into four divisions:—

No treatment.
Land treatment.
Chemical treatment.
Bacterial treatment.

These are not necessarily distinct, as more than one may occur in the one installation. But the four divisions are convenient.

The no treatment system is of very limited application. It has been ousted in succession from small streams, from large streams, and from tidal rivers. It has a rather precarious hold even on the sea, except where a specially suitable place of discharge can be found In our limited time we may with advantage confine our consideration to those methods of sewage disposal which involve more or less of treatment.

I might begin by referring to one or two popular fancies. One is that filtered sewage is good drinking water. It is not. A sewage effluent may be very good as a sewage effluent, and very bad as drinking water. Good drinking water should be free from any trace of sewage contamination; a good effluent is one from which the polluting matter has been partly removed, and in which the remainder has been rendered harmless. The analytical results which indicate the most satisfactory sewage effluent would utterly condemn the water for drinking purposes. There are many good effluents, many indifferent ones, and I fear still more bad ones, but I would decline the invitation to drink even the best.

Another popular fancy is that there is a "best" system of sewage disposal. It is quite natural that an inventor or patentee should think that his particular system is the best. We give him credit for perfect good faith even when he tries to convince us that it is equally applicable to works draining a populous area of many square miles, requiring inlet sewers in which men walk upright, where there is an equipment of elaborate machinery, where the tanks have to be in a more or less populous neighborhood and of great size, and where the discharge is into a large tidal river like the Clyde—the illustrations are from the Glasgow works—and to a work of modest dimensions, with no machinery, discharging into an inland stream. We take the liberty of thinking, however, that his opinion is prejudiced.

Even when a man is not an inventor, if his experience has been limited to a few examples, he is very likely to draw rash conclusions, and to assume that because he has seen one system doing better than another the relative result will always be the same. In doing so he forgets two things—first, the suitability for local conditions; and, second, the personal element.

In speaking of the personal element, I do not refer chiefly to those who are responsible for the design and supervision of the construction, nor to our useful, if somewhat rough, friends who actually carry it out; but I refer especially to the men who, day in and day out, with sometimes little recognition of their care and ability, keep the works in proper order. I should like to repeat what I have often said before, that the efficiency of any sewage work, whether it is a big one like Glasgow or Birmingham (from both of which we have illustrations), or a work too small to require the

*Abstract of lecture before the Sanitary Association of Scotland, September 18th, 1912.

whole attention of one man, depends quite as much on its management as on its construction.

One of the most interesting duties in connection with sewage is to be called in, as a doctor is called in, because the works are "sick." Without touching on the highly controversial subject of medical men and contract practice, I am strongly of opinion that something of this nature might be useful in sewage works. The big work has its own skilled man, but the little work has to call in the doctor when its digestion goes out of order, and, like the human patient, it is apt to be pretty bad before the doctor, in the shape of the engineer, is called in. Much unpleasantness might be saved by a regular visit, and the administration of the necessary tonic before the patient's condition became serious.

It might be of interest to mention some of the common ailments:—

Overwork is the most common of all. This may either be general overwork, due to the deficient size of the installation; or local overwork, due to the bad distribution of the work, in other words, of the sewage. This last is very common.

Faulty tanks, allowing too much suspended matter to reach the filter.

Filters clogged and requiring to be re-made.

Improper drainage of filters.

Some mechanism out of order.

These points will be better appreciated after some consideration of the various methods. The remedy, of course, depends on the exact nature of the trouble.

Of all the methods of treating sewage, it is probably correct to say that none has surpassed land treatment in producing a good effluent. It is not many years since (in England) it was compulsory to finish off with land, whatever the preliminary treatment may have been; and the general abandonment of land in recent years has not been because of its inefficiency, but on account of other difficulties, chiefly that of getting enough land. No further back than last month I heard at the York Congress of the Royal Sanitary Institute a strong plea for land treatment, and, although some of the arguments in its favor were far from convincing, it must not be supposed that this treatment is altogether out of date. The stock argument, that it is a more "natural" process, reminded me of the reasoning of Mause Headrigg in "Old Mortality." She objected to her son being called on to use fanners for winnowing corn, "instead of waiting patiently for whatever dispensation of wind Providence was pleased to send."

Natural or not, land treatment may give excellent results; but when one bears in mind that under the system of broad irrigation, from which alone good farming results are to be expected, an acre will not serve for a population of more than 100, and that with the most concentrated system of land filtration an acre of actual filter is needed for every thousand of the population, it is easy to see why processes which do the work on a very much smaller area are usually preferred. It is simply out of the question in the case of a large town to obtain a sufficient area of suitable land; even a small town finds it difficult. An artificial filter will deal with a population of many thousands per acre.

Almost every form of treatment begins with rough screening, which removes such things as dead cats and old boots, and which in a large work results in a great volume of refuse. This is usually combined with a settling tank for the rougher grit. In Glasgow this is taken out of the tank by a dredger.

In land treatment there is no other preliminary, but the chemical and bacterial methods of treatment have preliminaries which are vital parts of the process.

Before speaking of chemical and bacterial methods, it is desirable to refer to the composition of sewage from a mechanical point of view.

Sewage consists of water, with polluting material partly dissolved and partly suspended.

The scum is of little consequence. Most of it ultimately disintegrates and either dissolves or sinks. The sludge is a very different matter.

It has certain manurial value, but with about 10 per cent. of manure you have about 90 per cent. of water. It does not pay, therefore, to carry it far, and in the immediate neighborhood of a large town the demand for manure is limited. It is possible to get rid of some of the water by allowing the sludge to settle in large tanks, as is done in the Glasgow works at Dalmuir and Shieldhall. Still more can be got out by drainage on filters, as is well illustrated by a series of views from Birmingham. A still further advance is made by filter-pressing, as is done at Glasgow Dalmarnock works. And, finally, at the same works a valuable and compact manure is produced by further drying the filter-pressed sludge. But raw sludge is of so little value that where water transport is readily available, as at Dalmuir and Shieldhall, the method which is adopted is that of taking the sludge out to sea and depositing it in deep water.

Leaving for a time the question of filtration, let us look at the bacterial process. Their war-cry for a time was "No sludge," but that, I think, has been dropped or modified.

Everybody has heard of the septic tank. When I had the honor of addressing this congress from the chair in 1898, I described a pilgrimage which I had made a year or two earlier to Exeter to see what was then the last word in sewage purification, and which was hailed as a complete solution of the sewage problem. It has certainly been of great value, but the septic tank is in itself no solution of the sewage problem. The Royal Commission has reported adversely on some of its chief claims.

The name took the public fancy. It became familiar to many who knew little about sewage, and the microbes who inhabit these tanks have become familiar friends. Many people seem to be on fairly intimate terms with them, and to know that their chief occupation is that of eating each other up. I have been gravely assured that this process of mutual consumption can be watched, and I have heard an emphatic condemnation of a tank on the ground that no microbes could be seen in it. Thousands of people who know nothing whatever about sewage purification will tell you, without the slightest hesitation, that the proper way to purify sewage is by means of a septic tank. They sometimes spell it "sceptic," which describes exactly the proper mental attitude to such a proposal. It is no exaggeration to say that nowadays one of the difficulties in dealing with sewage is to convince those concerned that anything more is needed than to construct a big cesspool, and to call it a septic tank.

It is quite true that the early septic tanks wrought for years with no great increase in the material deposited in the bottom, and it was not unnatural to conclude that most of the solids were dissolved. But experience has shown that when accumulation of sludge does not occur in the tanks, it simply means that the fine suspended matter is passing away in the tank liquor. Unfortunately, many tanks have been constructed with no convenient arrangement for removing sludge, in the belief that no sludge would be produced. This is one of the fancies for which local authorities have had to pay dearly. What happens is that, after a certain amount of accumulation has taken place, the liquid leaves the tank heavily charged with matters in suspension.

So far we have dealt with what may be called the early history of sewage disposal. This brings us to a compara-

tively new field of inquiry. The liquid which leaves the tanks, and which is now usually termed "tank liquor," contains always a large proportion of matter in solution, and usually a quantity of matter in suspension. With the former it is quite easy to deal. We can't remove it, but by proper appliances it can be oxidized and rendered harmless.

The required method is filtration. If the sewage is passed through a proper filter, to which the oxygen of the air has free access either periodically or all the time, the filter, like the tank, will soon swarm with minute life. This life is instrumental in bringing the sewage matters and the oxygen into intimate contact, so that the sewage matters are burnt up by the oxygen.

In order to have this done effectively, it is essential that the sewage be divided into the smallest possible parts, so that the microbes may come into contact with all of it. This division may be effected in various ways—the liquor, for example, may be sprinkled on the top of a filter, or it may be poured on in bulk and allowed to find its way through the interstices of the material—but somewhere and somehow it has to get through small openings. If the liquor contains only dissolved matter, it will pass freely through these small openings; if it contains suspended matter, it will soon choke them up.

The importance of this is not realized as it ought to be. It is good policy to spend money and trouble in getting a tank liquor which is reasonably free from suspended matter.

It is much cheaper to clean a tank than to clean a filter, even when the tank has not been well designed for the purpose; while with a well-designed tank there is no comparison. This is a branch of sewage engineering to which far too little attention has been given.

I do not mean that it has been ignored by those who are really experts; but in ordinary works the design of the tanks is usually the weakest part. Even in works of considerable size, the tanks too often show evidences of the belief that the sludge will disappear, and that no provision for its removal is required.

On the other hand, some very ingenious systems have been devised, with the object of getting the solid matters out of the main stream of sewage. There are three tanks of which a good deal is heard—Dr. Travis's hydrolytic tank, the Imhoff tank, and the Dortmund tank. Of the two former I will only say that in them the sludge which settles out from the sewage is encouraged to pass through openings in the bottom of the channel into a part of the tank where there is little or no flow. With the long and comparatively narrow tank common a few years ago, the sludge might settle down, but it could not get out of the current. Everybody is familiar with the manner in which a person may be swept along by a crowd in a narrow passage; he may be most unwilling to go on, but he has no choice. But if there are side passages or recesses here and there, the person who wishes to stay behind gets into one of these. Much the same principle applies in these tanks. They are somewhat complicated in construction, and the question of whether or not it is worth while to use them must be settled for each individual case.

The Dortmund tank is better known. It was first employed at the town of Dortmund, whence its name. For a while it had no great popularity, but it is now very often used. In principle it is little more than a deep pit with sloping sides, down which the sewage matters fall, while the liquid passes over the top.

But supposing the sludge to be satisfactorily caught in such a pit, how is it to be got out? It would be a very troublesome operation, and a very offensive one to empty the tank every now and then to get out the sludge. If you make a hole in the side of a tank full of sewage the sewage will run out, or if the hole is made into the part which is filled with sludge, it is the sludge that will come. If you provide a pipe dipping down into the sludge, and coming out below the surface level, the sludge will come out near the surface level; and if you provide the pipe with a valve, it is quite easy to wait until the sludge has gathered, open the valve, and let the sludge run out, and shut the valve whenever the sludge has been removed. By such an arrangement it is easy to remove the sludge as often as may be necessary without disturbing the tank to any extent, and therefore with comparatively little smell. It is well to say comparatively, for there are few operations connected with sewage that don't smell more or less, and it is of the utmost importance to have as little handling of it as possible. Various methods of dealing with the sludge after it has been got out have already been mentioned. Another method which has recently been devised is to spread in a special tank a layer of stable litter, then run in a layer of sludge, spread another layer of stable litter, and so on. The great point is to get the sludge as free from water as possible, so that it may become fairly portable, and thus available as manure. The liquid which drains from it is, of course, very foul, and unless it can be properly filtered in some other way it is pumped back into the tank among the sewage. Fortunately, there is not very much of it.

There is no time to do more than mention "slate beds," where the sewage enters not a large unoccupied space, but a space provided with numerous slate shelves, so that the deposited matters may be more fully disintegrated.

We may now return to the liquid which leaves the tank, whether the tank is a precipitation tank, a septic tank, or a sedimentation tank. It is no longer crude sewage, but what is known as "tank liquor." It is very far from being pure water, and has still to be filtered.

Here our friends the microbes have their second innings, and, with all respect to the anaerobic branch of their family, most sanitarians are agreed that the aerobic microbes are more to be trusted. We have got out of the sewage everything that we can by a rough process of settlement, aided by any breaking up or dissolving that may take place. The tank liquor is tolerably clear—if our tanks have done what they should—but it is full of putrescible matter, dissolved if not suspended. We want to get this putrescible matter oxidized, and so rendered harmless.

We do this by getting it into close contact with pieces of filtering material, swarming with bacteria, and see that these bacteria are liberally supplied with oxygen, that is to say, with fresh air. This close contact is not so easily got.

Two methods have been adopted. The one is what is known as the "contact bed," the other as the "percolating" or "streaming" or "continuous" filter.

The contact bed consists of a big tank, usually about 3 or 4 feet deep. It is filled with the "filtering medium"—usually clinker or some such material broken into pieces about the size of road metal. Many materials have been used, and many different sizes have been tried.

Of course, there is still a good deal of space left between these pieces, and into this space the sewage is run. Roughly speaking, the filtering material occupies about two-thirds of the total space, and the liquid about one-third. By this means of working there is no question that the sewage must be brought into close contact with the filtering material. Suppose the filtering material to be covered with a multitude of microbes, each fed up with fresh air and hungry for sewage, it follows that when the sewage is let into the bed these microbes promptly set to work. After a while, however, they become fed up with sewage, and want more fresh air, not to speak of time for digestion. The liquid, therefore, must be run out of the bed to let the fresh air in. The whole process

is an intermittent one, and consists of four stages—filling, standing full, emptying, standing empty. It follows that there must be more than one bed, so that at all times one may be filling. Very often the number is considerable; five is a convenient number, so that one may be in each of the four stages, and one taking a rest.

The original septic tank installation was of this type. A most ingenious set of tilting buckets was employed, so that all the changes were wrought automatically. When a bed was full the flow of sewage was turned on to the next. When it had stood full for a certain time it was allowed to empty, all by these automatic contrivances. Since then many other methods have been devised for controlling the operations, most of them depending on syphon action.

This method of filtering sewage has fallen on evil days. The Royal Commission has issued a report which is not very favorable to it, and in the future it is probable that contact beds will be the exception. The report showed that, when original cost and running expenses are both taken into account, contact beds are not such an economical method of dealing with sewage as are percolating filters. It must not be forgotten, however, that they have certain advantages, not the least being that they are much less likely to cause offensive smells than some other methods. But any method of sewage disposal is ready to cause smell on very slight provocation.

The other method is to sprinkle the tank liquor on the top of the filter like a shower of rain, or like a dose from a watering can. At first sight it might appear that nothing is easier than to water the surface of a filter with fair uniformity, giving each part an equal share of the liquid. In fact, it is far from easy, and of the failures which have occurred in sewage purification a big proportion may be traced to failure in this particular.

Look at the matter in this light—In designing a sewage filter, the first thing to be considered is the amount of work it has to do. Having ascertained this as nearly as he can, with, of course, a proper provision for uncertainty and for future extension, the engineer calculates what size of filter will be needed, and the filter is constructed of a capacity to fit the work to be done. A well-designed system is based on each part of the filter doing its proper share of the work. But if the distribution is so bad that one part of the filter does no work or far too little, it follows that the other parts get more than their share to do. Some filters have been designed rather extravagantly, and are too big for their work, in which case bad distribution may not cause any visible harm. But if the filter has been well proportioned, bad distribution soon results in bad effluent and offensive smells. A sewage filter which is working well has no serious smell; but a filter which has been overwrought, and has become "sewage sick," takes a prominent place among nuisance producers. It is very false economy to have bad distribution; it must be paid for either in extra size of filter or in nuisance.

In big works, where power-driven appliances are in use, it is quite common to use power to drive the distributors. In that case it is fairly easy to get good distribution, and, besides, in such a place there is skilled attendance to put right at once anything that may go out of order. There is little doubt but that the best results which have been attained have been under these conditions.

But in small works the sewage has to distribute itself, the power being derived from its own fall. More than that, the fall that can be given is usually very limited, and many inventors have been at work on the problem of how to distribute the liquid which comes from the tank, keeping in view that the surface level of the filter should be as nearly as possible the same as the level of the sewage in the tanks. It often happens that between the sewage level in the tanks and the level of the bottom of the filters there is nothing to spare, and any fall required to distribute the liquid must simply mean a reduced depth of filter.

Much ingenuity has been displayed in meeting this requirement, and a number of prominent methods will be illustrated. They may first be classified as follows:—

1. Distributors which are fixed.
2. Distributors which move.

The first class contains the following:—

(a) A gridiron of perforated pipes.—This is not often used on a large scale, being apt to choke up, and also being irregular in its distribution.

(b) Trays.—These have the advantage of not requiring much fall, but it is difficult to maintain even distribution. The large surface of exposed liquor adds materially to the risk of nuisance from smell, while the trays hinder the free access of light and air. Installations of this type are very common.

(c) Sprays.—These are only available when there is plenty of fall. In favorable circumstances they are the cheapest of satisfactory distributors.

They have been adopted as the standard type at the Birmingham filters, probably the largest in the kingdom. In Scotland the Crieff sewage is distributed by these sprays with very satisfactory results. Many varieties of jet have been tried, the object being to secure freedom from choking, and at the same time to throw the spray horizontally over the bed and not to send it much into the air. Otherwise the risk of smell is considerable. The jet shown was a great improvement on the earlier types.

Of the second, the following are in common use:—

(a) Revolving distributors with perforated arms.—The perforations are on one side of each arm, and the reaction causes the whole apparatus to revolve. The system is a clever adaptation of "Barker's Mill," which was otherwise little more than a scientific toy. The trouble is that the holes are necessarily small, and thus apt to choke. Various mechanical devices have been applied to the clearing of the holes, and several very ingenious systems of suspending the apparatus so as to revolve with the minimum of friction are on the market. The principle is in very common use.

(b) Revolving distributors driven by central turbine.—In order to avoid the difficulty of the small holes this method of driving has been used. The reaction of the arms is not needed for driving, and so the arms are open troughs, over the edge of which the liquor spills as they revolve.

There is a risk in either of these types that with a very small flow the revolution may stop. It is usual, therefore, to pond up the tank liquor when the flow is small, so that it is discharged not in a continuous dribble, but in a succession of rushes. These distributors, therefore, in dry weather are usually working and resting in fairly quick succession. There is nothing against this, except that the necessary syphons introduce an extra complication.

(c) Revolving distributors of the water wheel type.—These are driven by the weight of the liquor, which is delivered into the buckets by a feed pipe. The distributor is a long drum, pivoted at one end and carried by a driving wheel on a rail at the other. As the drum turns it moves along and so spills the liquor over the filter. It is a more cumbrous and costly apparatus, but does excellent work. On a large scale care has to be taken to balance it by having two arms, otherwise the wind might hinder its movement.

All the foregoing require that the filters should be circular. It sometimes happens that the ground is more suit-

able for rectangular filters, or that percolating filters are used to replace contact beds, hence the introduction of the next type.

(d) Travelling distributors of the water wheel type.—In principle these are identical with those just mentioned. The feed, however, instead of coming from the centre, is taken by a syphon from a long trough. In the most recent type the weight is carried chiefly by one central rail, a small proportion resting on the trough for balancing purposes.

Most of the methods are the subject of patents, some of them of many different patents. Each manufacturer, quite naturally and not improperly, does his best to keep his wares before the public, and the wares, as a rule, are good. The variety of apparatus, all designed to perform the same apparently simple operation, is somewhat bewildering. When a man sees an installation working well, and producing a high-class effluent, he is naturally inclined to say that the system must be a first-class one, and he is apt to conclude that he need only adopt that particular system in order to produce as good a result elsewhere. That is a dangerous fancy. It is not only the effluent that must be considered. I have in my mind two works, one producing an effluent which to appearance is spring water, and which gives analytical results which are entirely satisfactory. The other produces an effluent which shows evident signs of being other than clean water. One might say that the first works were much better than the other. But I believe that the latter works are purifying the liquid to a greater proportional extent than the former. The sewage in the one case is from a residential town, with a liberal supply of water; the sewage in the other is from a mining village, where the supply of water is very limited. When the comparison is made between the sewage entering the works and the effluent in each case, it is realized that effluent alone is not a fair test.

It is not only the distribution that affects the efficiency. The essence of filtration is that the liquid and the oxygen of the air are brought into contact. It is useless to supply the filter with liquid unless it is also supplied with air, and if the bottom of the filter gets choked either with water or with rubbish, there is no chance of air getting into the body of the filter. Accordingly, it is important to have the bottom of the filter freely supplied with channels by which the water can escape and the air enter.

Look also at the different kinds of filter wall. In some cases the filtering material is merely a bing with no contain-walls; in others there is a "dry stone dyke" to hold in the material, or there is a rough wall built of the bigger lumps of the material itself. Then, again, there is ordinary brickwork, and in other cases there is "pigeon-hole" brickwork. The idea of the open walls is to allow air to enter more freely, but the general opinion now is that if the bottom of the filter is well ventilated it matters little how the walls are constructed. The real test is economy in its broad sense, and it is rather amusing, on the one hand, to hear it argued that walls are an unnecessary extravagance, and that the material should be allowed to take its own natural slope; and on the other, that the extra material thus required and the extra land occupied would cost more than the wall. The relative cost, of course, depends largely on local conditions, but personally I would be inclined to have a wall of some sort, however rough, if it were only for the sake of keeping the place more tidy.

The subject of sewage disposal is becoming more and more complicated. At one time the choice of system was made, as it were, in the mass; the decision to adopt land treatment, chemical treatment, or septic tank treatment, covering practically all the general arrangements. Nowadays the usual thing is to adopt what may be called septic treatment, but which I much prefer to call "bacterial" treatment, as being a wider description; but the choice then [illegible] beginning. The shape and capacity of the tanks, the method of working them, the removal and subsequent disposal of sludge, the application of the liquor to the filters, the shape of the filters, their depth, the kind of material and the size of the pieces, the drainage of the filters—these are only some of the problems which have to be solved, and the solution of one does not always help in the solution of the next. Frequently the balance between different courses is extremely fine, and in many instances it would be impossible to say dogmatically that one was right and the other wrong.

There are quite a number of different systems, any of which will work quite efficiently if the details are skilfully designed and the working efficiently supervised, and it is quite possible that two equally competent men may arrive at quite different designs. The economical solution of the problem calls for two things—a thorough knowledge and clear grasp of general principles, and a thorough and detailed investigation of the special conditions of the place. The most economical system is not always that which is apparently cheapest; on the contrary, economy and cheapness are often very different things.

The difficulty is emphasized by the fact that the money to be spent is public money, and those responsible for the expenditure are very properly jealous of any unnecessary cost. Not being themselves experts, they are apt to take any promise of cheapness at its face value, forgetting that an estimate may be very reliable or very sanguine. In England, where many local authorities invited competitive schemes, and adopted what promised to be the cheapest, many cases have occurred where the final cost bore only a distant resemblance to the original estimate. The intervention of the local government board, who called pointed attention to these costly object lessons, pretty well killed that practice there, and I have sufficient faith in Scottish shrewdness to expect that the lesson will be taken here without many such experiences.

EXPANSION IN RAILWAY BUILDING.

The Canadian Northern Railway and its subsidiary companies disposed of $28,960,000 securities in 1912, or 41 per cent. of the year's total.

The Grand Trunk Railway required heavy financing during 1909, 1910 and 1911, but in 1912 issued no securities to the public. Under a special arrangement, we understand, certain advances were made to this company by the Dominion Government. The Grand Trunk Railway in 1912 issued securities aggregating $19,800,000, as compared with $10,000,000 in 1911. The issuance of equipment trust notes by the Grand Trunk Railway is worthy of special mention in that for the first time this company availed itself of this modern and reasonable method of financing its equipment requirements. These obligations found a ready market in the United States.

The Canadian Pacific Railway made its annual issue of 4 per cent. consolidated debenture stock, aggregating $10,962,320, proceeds of which were used to build branch lines, purchase additional steamships and to acquire the bonds of subsidiary companies. Its larger requirements are met by the sale of capital stock, of which $18,000,000 was issued in 1912, with an additional $60,000,000 in immediate prospect.

The construction of the Edmonton, Dunvegan and British Columbia Railway is the first serious attempt to open up that part of Northern Alberta commonly known as the Peace River country.

The aggregate production of lode gold in British Columbia up till 1912 was 3,421,000 ounces (fine) of $70,497,000. The placer gold amounted to $72,130,000, making a total of $142,636,000. The Yukon shipped out $169,000,000.

ASPHALTIC CONCRETE AND SHEET ASPHALT PAVEMENTS.*

Asphaltic Concrete Pavement.

Subgrade and Drainage—H-1.—The subgrade and drainage shall be constructed to the plans, profiles and specifications of the City Engineer.

Foundation—H-2.—The foundation upon which the pavement is to be laid shall be concrete, and shall be prepared according to specifications and requirements of the City Engineer.

Wearing Surface.—H-3.—Upon the prepared foundation shall be laid the asphaltic concrete wearing surface, consisting of a mixture of selected, hard, crushed stone, gravel and sand, mixed with asphaltic cement as hereinafter specified. The wearing surface shall be of a thickness of 2 in. after thorough compression with a roller weighing not less than 200 lbs. to the inch width of tread, and shall contain between 7 and 12 per cent. bitumen soluble in carbon disulphide, depending on the mineral aggregate treated.

Mineral Aggregate—H-4.—Stone.—The stone shall be crusher run varying in size from a maximum of ½ in. to the smallest particles retained on the finest mesh screen commonly used on crushing plants. The dust or fine screenings should be completely removed from the stone, as it is usually excessive and irregular in quantity and necessitates the use of a greater amount of asphaltic cement. Sufficient sand and filler, varying from 8 to 15 per cent., shall be added to completely close and fill the interstices of the mineral aggregate. After being rolled the surface shall present a granular appearance, showing that the structural body of the pavement is crushed stone. The asphaltic cement shall be in sufficient quantities to bind and fill the mixture as specified above, but not to flush to the surface as free cement under the roller.

Sand.—Sand shall be clean, moderately sharp and well graded, and shall be free from loam.

Mix.—The mix shall consist of a mixture of sand and stone as above specified, so as to comply with the following specifications:—

Passing 100 x 200-mesh sieve		8 to 15%
Passing 80-mesh sieve	10 to 20%	Mineral aggregate
Passing 40-mesh sieve	15 to 30%	
Passing 10-mesh sieve	30 to 40%	
Passing ¼-in. ring	15 to 40%	
Passing ½-in. ring	0 to 30%	

Method of Mixing—H-5.—The aggregate shall be thoroughly dried in properly designed driers before mixing with the bitumen. The driers shall be of the revolving type, thoroughly agitating and turning the materials during the process of drying. When the aggregate is thoroughly dried and heated to a temperature of from 200 to 350° F. (depending upon the asphaltic cement used), it shall, immediately before cooling or exposure to moisture, be mixed with the hot asphaltic cement as hereinafter specified.

The asphaltic cement shall be melted in a tank arranged so that the heat can be properly and easily regulated. When melted and raised to a temperature of from 200 to 350° F. (depending upon the asphaltic cement used), it shall be combined in proper proportions with the hot aggregate and immediately mixed in a properly designed mixer with revolving blades until a thorough and intimate mixture of the ingredients has been accomplished, and the particles composing the aggregate evenly and thoroughly coated with the asphaltic cement.

Laying—H-6.—Paving mixture at a temperature of from 200 to 350° F. shall be hauled on to the street in dump wagons, and shall be kept well covered with canvas to retain the heat, and dumped and shoveled into place. While it is still hot it shall be evenly spread with hot iron rakes, and while still pliable shall be rolled with a steam roller as above specified, so that when ultimate compression is accompilshed the surface shall be even and true to grade. The rolling must be steadily kept up, lengthwise, crosswise and diagonally, and continued until all roller marks disappear and surface shall give no appearance of further compressibility. Along the curb, around manholes and catch basins, where roller cannot reach, the required compression shall be made by the use of hot iron tampers. Tamping shall be done as quickly as possible after the material is spread, while it is still hot and pliable.

Joints—H-7.—All contact surfaces along curb, around manholes, castings, etc., shall be painted with an asphaltic cement before the paving mixture is laid.

The paving shall be done continuously, so that the number of joints between the hot and cold material shall be reduced to the minimum. When it is not practicable to lay it continuously, and a joint is unavoidable, the edge of the cold material shall be trimmed down to a rough feather edge and the surface where the joint is to be made painted over with asphaltic cement, and the hot material raked over the feather edge and thoroughly rolled; or, instead of trimming the cold material, joint strips may be used, consisting of strips of canvas about 18 in. wide, with three parallel lines of ¾-in. ropes sewed on the underside about 3 in. apart; the joint strips shall be laid on the feather edge of the freshly raked materials, with the upper rope at the line where the thickness begins to decrease, and the rolling completed on top of the canvas as for finished pavement.

Asphaltic Cement—H-8.—The asphaltic cement shall be composed of refined asphalt and flux.

Refined Asphalt—H-9.—The refined asphalt to be used under these specifications shall be approved and in every way satisfactory to the City Engineer. The refined asphalt shall be equal in quality to the recognized standards, and must comply with the following requirements:—

(1) All shipments of any one kind of material shall be uniform in consistency and composition, and shall not vary more than 15 points in penetration at 77° F.

(2) When the refined asphalt is made into an asphaltic cement by use of flux hereinafter specified it must produce an asphaltic cement of the required penetration satisfactory to the condition of the street, and at the penetration at which it is to be used it must comply with all requirements set forth herewith for asphaltic cement.

Fluxes—H-10.—The fluxes shall be residues obtained from the distillation of paraffin, asphaltic or semi-asphaltic petroleum. They must be homogeneous and of a uniform gravity, and free from all signs of cracking, and must comply with the following requirements:—

(1) They shall have a specific gravity at 77° F. of between 0.92 and 1.04.

(2) When 20 grms. of flux are maintained at a temperature of 170° C. for five hours in a cylindrical vessel 2½ in. in diameter there must not be volatilized more than 5 per cent. by weight.

(3) They shall not flash below 180° C. when tested in a New York State closed oil tester.

(4) They shall be soluble in carbon bisulphide to the extent of 30.5 per cent.

The asphaltic cement prepared as above described must comply with the following requirements:—

(1) It must be homogeneous, adhesive, viscous and must not be affected by the action of water.

---

* Specifications adopted by Vancouver, B.C.

(2) It shall have a penetration of between 50 and 70 per cent. at 77° F.

(3) When 20 grms. of asphalt are maintained at a temperature of 150° C. for five hours in a cylindrical vessel 2½ in. in diameter there must not be volatilized more than 5 per cent. by weight, nor shall the original penetration be reduced thereby over 50 per cent.

(4) The asphaltic cement shall not be so susceptible to changes in temperature as to have a penetration varying more than 125 between 0 and 45° C., and it shall have a ductility of not less than 5 cms. at 25° C., and not less than 2 cms. at 0° C. (Dow Standard).

Squeegee Coat—H-11.—Immediately after rolling, and while the pavement is still warm, a thin coat of pure bituminous cement shall be spread over the surface by means of rubber squeegees, and upon this shall be spread a thin layer of stone chips or other suitable material, dry and free from dust, and containing no particles which shall be less than ¼-in. ring nor greater than ½-in. ring. After applying dressing the surface shall be again rolled until it presents a smooth and finished appearance, subject to the approval of the Engineer.

Sheet Asphalt Pavement.

Subgrade and Drainage.—[The Subgrade and Drainage and the Foundation Requirements are the same as those given above for asphaltic concrete.—Ed.]

Binder Course—C-3.—The binder course shall consist and be made up and laid of what is known to the asphalt trade as "compact," or "coles" binder, and shall be composed of hard, clean broken stone (no gravel will be allowed or used in the mixture), which shall pass an opening 1 in. in diameter, the voids in which are filled with finer stone passing an opening ⅜-in. in diameter, while the voids in the mixed stone shall be filled with a well-graded sand.

To the stone and sand aggregate (after thorough mixing) sufficient asphalt cement shall be added to thoroughly coat the mineral aggregate with bitumen without showing any excess on compression with a hot tamper.

The stone and the asphalt cement shall be heated separately to such a temperature as will give, after mixing, a binder of the proper temperature for the material employed. The stone when used must be at a temperature between 200 and 335° F. The asphaltic cement when used must be at a temperature between 250 and 350° . The asphaltic cement and stone shall be thoroughly mixed by machinery in such proportions that the resulting binder shall have life and gloss without an excess of asphaltic cement, and the mixing shall be continued until a homogeneous mixture is produced in which all the particles are thoroughly coated with asphaltic cement.

Asphaltic Cement for Binder — C-4.— The asphaltic cement for the binder course shall have a consistency of at least 20 points, as indicated by the Bowen machine, higher than that in use in the surface.

Laying — C-5.—The binder mixture, prepared in the manner described, shall be brought to the street in wagons at a temperature between 200 and 325° F., and shall be covered with canvas covers while in transit. The temperature of the binder mixture within these limits shall be regulated according to the temperature of the atmosphere and the working of the binder. On reaching the street it shall at once be dumped on the concrete, and then be deposited roughly in place by means of hot shovels, after which it shall be uniformly spread by means of hot iron rakes, and then at once be thoroughly compacted by tamping or rolling. The depth of the finished binder shall average not less than 1 in. in thickness, and its upper surface shall be parallel to the surface of the pavement to be laid. The surface, after compression, shall show at no place an excess of asphalt cement, and any spot covering an area of 3 sq. ft. or more showing an excess of asphalt cement shall be cut out and replaced with other material. All binder which shows lack of bond, or that is in any way defective, or which may become broken up before it is covered with wearing surface, must be taken up and removed from the street and replaced by good material properly laid in accordance with these specifications at the expense of the contractor. Binder when laid shall be followed and covered with wearing surface as soon as is practicable in order to effect the most thorough bond between the binder and the wearing course. The binder course shall be kept as clean and free from traffic as is possible under working conditions. If necessary it must be swept off immediately before laying the wearing surface on it.

No binder shall be laid when in the opinion of the Engineer the weather conditions are unsuitable, or unless the concrete on which it is to be laid is dry and has set a sufficient length of time.

Wearing Surface.— C-6.—The wearing surface shall be composed of sand, filler and asphaltic cement, as hereinafter specified, mixed in the proper proportions.

Sand.—The sand must be clean, moderately sharp, and having a grading not varying more than 5 per cent. from the following limits; i.e., 5 per cent. from the three combined gradings:—

Standard Grading.

Bitumen		12.0%	
Passing 200-mesh	14.0%	.0000%	
Passing 100-mesh	12.6%	0.1702%	
Passing 80-mesh	10.4%	0.1405%	= 31.7%
Passing 50-mesh	23.0%	0.3108%	
Passing 40-mesh	10.0%	0.1351%	= 44.6%
Passing 30-mesh	9.0%	0.1210%	
Passing 20-mesh	5.0%	0.0620%	
Passing 10-mesh	4.0%	0.0540%	= 23.7%

Filler.—The filler must be thoroughly dried limestone, or other inorganic dust, or Portland cement. The whole of it shall pass a 30-mesh screen, and at least 70 per cent. of it shall pass a 200-mesh screen. From 5 to 15 per cent. of dust shall be added to the surface mixture, depending upon the kind of dust used, grading of sand, and traffic conditions of the street.

Asphaltic Cement.—[Same as for asphaltic concrete, given above.—Ed.]

Preparation.—C-8.—The wearing surface shall be composed of sand, filler and asphalt cement of the character elsewhere specified, and mixed in proper proportions. The sand and asphaltic cement shall be heated separately to such a temperature as will give, after mixing, a surface mixture of the proper temperature for the materials employed. The sand when used must be at a temperature between 250 and 375° F. The asphalt cement when used must be at a temperature of between 250 and 350° F. The filler shall be added to the hot sand in the required proportions and the two thoroughly mixed. The asphalt cement in the proper proportions shall then be added, and the mixing continued for at least one minute in a suitable apparatus until a homogeneous mixture is produced in which all particles are thoroughly coated with asphalt cement. The weights of all materials entering into the composition of the wearing surface shall be varied in the presence of inspectors as often as may be required, and the Engineer or his representative shall have access to all parts of the plant at any time.

Laying—C-9.—The surface mixture, prepared in the manner above described, shall be brought to the street in wagons at a temperature between 230 and 350° F., and shall be covered with canvas covers while in transit. The temperature of the surface mixture within these limits shall be

regulated according to the temperature of the atmosphere and the working of the mixture and the character of the materials employed. On reaching the street it shall at once be dumped on a spot outside of the space on which it is to be spread. It shall then be deposited roughly in place by means of hot shovels, after which it shall be uniformly spread by means of hot iron rakes in such a manner that, after having received its final compression by rolling, the finished pavement shall conform to the established grade and have a thickness of not less than......in. Before the surface mixture is placed all contact surfaces of curbs, manholes, etc., must be well painted with hot asphalt cement. After raking, the surface mixture shall at once be compressed by rolling or tamping, after which a small amount of cement shall be swept over it, and it shall then be thoroughly compressed by a steam roller weighing not less than 200 lbs. to the inch width of tread, and the rolling being continued until a compression is obtained which is satisfactory to the Engineer. Such portions of the completed pavement as are defective in finish, compression or composition, or that do not comply in all respects with the requirements of these specifications, shall be taken up, removed and replaced with suitable material, properly laid in accordance with these specifications, at the expense of the contractor. Whenever so ordered by the Engineer a space of 12 in. next the curb shall be coated with hot asphalt cement, which shall be ironed into the pavement with hot smoothing irons.

No wearing surface shall be laid when, in the opinion of the Engineer, the weather conditions are unsuitable, or unless the binder on which it is to be placed is dry. The finished pavement must be well protected from all traffic by suitable barricades until it is in a proper condition for use.

Requirements—C-10.—The finished pavement shall contain not less than 12 per cent. of bitumen soluble in cold carbon disulphide, depending upon the mesh composition and the character of the sand used and the traffic to which it is to be subjected, but in all cases sufficient asphalt cement must be used to properly coat all the particles of the mineral aggregate. It must also contain not less than 10 per cent. of mineral matter passing a 200-mesh sieve, and not less than a combined total of 25 per cent. passing the 200-, 100- and 80-mesh sieves. On streets of light traffic, when the Engineer has approved the use of a coarser sand or mixture than that specified for general use, the surface mixture must contain not less than 5 per cent. of mineral matter passing a 200-mesh sieve, and not less than a combined total of 18 per cent. passing the 200-, 100- and 80-mesh sieves. The maximum amount of 200-, 100- and 80-mesh material in the pavement will be regulated according to the kind of sand and asphalt used and the traffic upon the street on which the pavement is to be laid, subject to the maximum requirements elsewhere herein specified under sand and filler.

The above limits as to mesh compositions and per cent. of bitumen are intended to provide for such permissible variations as may be rendered necessary by the raw materials used and the character of the work to be done. The composition of the wearing surface may be varied within the limits above specified at the discretion of the Engineer, depending upon the kind of sand, filler and asphalt used and traffic conditions upon the street or streets to be paved.

Condition at Expiration of Guarantee—C-11.—In addition to the proper maintenance of the pavement during the period of guarantee the contractor shall, at his own expense, just before the expiration of the guarantee period, make such repairs as may be necessary to produce a pavement which shall:—

(a) Have a contour free from depreciation of any kind exceeding ½ in. in depth, as measured between any two points 4 ft. apart on a line conforming substantially to the original contour of the street.

(b) Be free from cracks, showing disintegration of the surface mixture.

(c) Contain no disintegrated surface mixture.

(d) Not have been reduced in thickness more than ⅜ in.

(e) Have a foundation free from such cracks or defects as will cause disintegration or settling of the pavement or impair its usefulness as a roadway.

GOOD ROADS EXHIBITION.

The first Good Roads Exhibition to be held in Canada will be in the Dairy Building, Toronto Exhibition Grounds, from the 24th inst., to March 1st.

The dates were set to be concurrent with the Toronto Motor Show and with the annual meeting of the Ontario Good Roads Association, which will be from the 26th to the 28th inst. The Exhibition will be under the management of Messrs. Hartley Robinson and E. M. Wilcox. The manager's office is 62 Temperance Street, Toronto.

Single fare on all railways for the entire week has been secured, and a good attendance is anticipated, both at the Motor Show and the Good Roads Show. There will be a number of interesting exhibits by the Patterson Manufacturing Company, Rocmac Road Construction Company, Ontario Bridge Company, Wettlaufer Brothers, The Canadian Engineer, Canada Cement Company, the University of Toronto, Sawyer-Massey Company, etc.

Delegates will be present at the meeting of the Ontario Good Roads Association from most of the cities, towns, villages and counties throughout the province, and highway officials from various parts of Canada and the United States will be present to address the meetings. Some of the speakers will be Sir Lomer Gouin, the Premier of Quebec, who has aroused that province this year to the importance of good roads; Colonel Sawyer, chairman of the Massachusetts Highway Board; Honorable A. R. Reaume, Minister of Public Works for the Province of Ontario; W. A. McLean, provincial engineer of highways for Ontario. County road organizations, construction of roads, maintenance, federal aid, provincial aid, and other subjects will be discussed.

The members of the association will undoubtedly find the Good Roads Show, which will be very handy to their meetings, both interesting and attractive. Both the practical and theoretical sides of road building will thus be presented, as sections of roads with practical demonstration will be seen at the show.

The Ontario Good Roads Association is a very important body of public-spirited men who have accomplished, among other things, the abolition of statute labor in many townships in Ontario; the adoption of the Highway Improvement Act in twenty counties, in which 3,771 miles of highway have been assumed for improvement; the expenditure of $3,393,507 in the improvement of county roads, one-third of which was paid by the province; and the appropriation by the province in 1912 of an additional $1,000,000 for the purposes of the Highway Improvement Act.

CONVENTION OF CANADIAN ELECTRICAL ASSOCIATION.

The Executive Committee of the Canadian Electrical Association of Toronto have decided to hold the next annual meeting of the association at Fort William on June 23, 24, 25. About 600 delegates and members from every part of the Dominion will be asked to attend.

COAST TO COAST.

Halifax, N.S.—The work of constructing the new No. 2 terminal pier at Deep Water has commenced. The construction, which is in charge of the Nova Scotia Construction Company is very interesting. At present concrete piles of 11 to 23 tons in weight are being driven into the sea bottom by a 16-ton steel hammer; 1,818 of these piles are necessary for the foundation of the pier.

Detroit, Mich.—The Great Lakes Engineering Works will construct three great steel car ferries for the Grand Rapids and Northwestern Railway to be used on Lake Michigan between Ludington and Manitowoe. The probable cost will be in the neighborhood of $1,500,000, and the boats will be built on the same style as the SS. Astabula, of the C.P.R. Company, but with a length of 350 feet.

Edmonton, Alta.—The provincial telephone system yielded a net profit of $62,283 for 1912. During the last six years the net profits have been $407,582. Premier Sifton reported that $2,000,000 will be spent to increase and extend the telephone system until every farmer and resident is accommodated with this utility, which is almost as necessary as railroads.

Montreal, Que.—Mr. Jos. Irving, in company with Hon. Clifford Sifton, is in London enlisting the support of English capital in the formation of the International Cement Company, of Hull, which was temporarily abandoned last spring. The company proposes to use a new process in the manufacture of cement and to have a capitalization of $10,000,000.

Montreal, Que.—The Canadian Ice Company, which is incorporated under a federal charter for $500,000, is doing its utmost to obviate the threatened ice shortage. Additional storage buildings are being built.

TORONTO UNIVERSITY ENGINEERING SOCIETY ANNUAL DINNER.

Thursday evening, February 13th, witnessed the twenty-fourth annual dinner of the Engineering Society of the University of Toronto, held at McConkey's, King Street West, Toronto. The affair was a general success, the attendance altogether being nearly three hundred members and guests. The programme of the evening had been arranged with care, and all present seemed to appreciate and enjoy it. Mr. J. E. Ritchie, the president of the Society, had the chair. The speakers of the evening were: Sir Edmund Walker, chairman of the Board of Governors of the University; Dr. R. A. Falconer, president of the University; Dean Galbraith; Dr. W. H. Ellis; Mr. David Molitor, consulting engineer and designing engineer of locks and dams of the Panama Canal, three years professor of Civil Engineering at Cornell University; Messrs. J. B. and J. W. Tyrrell; Mr. J. S. McCannell, president and general manager of the Milton Pressed Brick Company; Mr. J. L. Morris, the oldest graduate of the "School," and Messrs. T. V. McCarthy, D. A. Mutch and F. C. Mechin. Excellent music was supplied throughout the evening by the Science orchestra and the Science octette and others. The menu cards, of admirable and original design, were furnished by the Eugene Dietzgen Company.

Class '09 of the Faculty of Applied Science of the University of Toronto held a re-union dinner at the St. Charles in Toronto, Friday evening, February 14th. Over sixty members of the class were present on this occasion. Mr. W. D. Black, the toast master, was unanimously elected president for the ensuing three years.

PERSONAL.

RAY R. KNIGHT, recently appointed city engineer of Fort William, has left for that city.

JAMES G. LINDSAY, engineer and waterworks manager of Belleville since April, 1908, has resigned his position.

MR. JOS. D. EVANS has resigned his position as chief engineer of the Montreal Tramways Company to become construction manager of the Electric Bond and Share Company, of New York City.

MARCIL PEQUEGAT, honor graduate of '08 and instructor of drawing of the School of Practical Science, Toronto, has been appointed city engineer of Berlin, Ont. Forty applications were received for the position.

MR. ALVIN SCHLARBAUM, B.A.Sc., has severed his connection with Messrs. Smith, Kerry and Chace, as assistant engineer on the Healey Falls development, to accept the position of hydro-electric engineer for the Riordon Pulp and Paper Company, Limited, of Hawkesbury and Merritton, Ont.

H. T. HAZEN, government engineer in charge of the Hudson Bay Railway terminal at Port Nelson, has arrived in Winnipeg after completing the 700-mile journey from the mouth of the Nelson River. On Mr. Hazen's report will depend the Minister of Railways' decision on the location of the Hudson Bay port.

MONSIEUR J. M. F. de PULLIGNY, ingenieur en chef des Ponts et Chaussees, et Directeur, Mission Francaise d'Ingenieurs aux Etats-Unis, New York City, on February 11th delivered an illustrated lecture on "The Public Service of Roads in France," before the graduate students in Highway Engineering at Columbia University.

MR. ALFRED STILL has resigned his position as chief electrical engineer to the mines department of the Algoma Steel Corporation of Sault Ste. Marie, Ontario, Canada, to take charge of the courses in electrical design at the School of Electrical Engineering, Purdue University, LaFayette, Indiana. Mr. Still, who is a member of both the British and American Institutes of Electrical Engineers, has made a special study of hydro-electric developments and long-distance transmission of electric energy. He has lately returned from a trip to Denver, Salt Lake City, and San Francisco, where he has visited many of the important power systems.

OBITUARY.

MR. WM. JOHNSTON SPROULE, M.E., died at his home at St. Lambert, Que., February 6. The deceased was a member of the Canadian Society of Civil Engineers and was connected with the Montreal habor commissioners for 30 years as assistant engineer, retiring two years ago.

GEORGE WILLIAM MAYNARD, mining engineer, who introduced the Thomas basic steel process into the United States, and who had been widely known in the West and abroad as a consulting engineer, died at Boston, Mass., on February 13. His home was in New York, where he was born in 1839. He was one of the original members of the American Institute of Mining Engineers.

JOHN FRITZ, one of the best-known mechanical engineers in the United States, died at the age of ninety years at his home in Bethlehem, Pa., on the 13th inst. Among other positions of responsibility held at various times by Mr. Fritz were the general superintendency of the Cambria Iron Works, at Johnstown, Pa., and the general superintendency of the Bethlehem Steel Works. In 1864 Mr. Fritz built a rolling mill at Chattanooga, Tenn., for the United States Government, and in the years that followed he was an active

factor in the development of the Bessemer process, the acid and basic open-hearth and the electric furnace. He was a past president of the American Society of Mechanical Engineers; a past president of the American Institute of Mining Engineers; a member of the American Society of Civil Engineers; an associate fellow of the American Academy of Arts and Sciences; and honorary vice-president of the Iron and Steel Institute of Great Britain. From the last named society he received the Bessemer gold medal in 1893 for notable service in advancing the manufacture of steel. He was awarded the John Fritz medal by the United Engineering Societies in 1902, and the Elliott Cresson medal in 1910.

AMERICAN SOCIETY MECHANICAL ENGINEERS.

The American Society of Mechanical Engineers will hold a joint meeting with the Verein Deutscher Ingenieure in Germany, beginning June 22nd, 1913. The principal industries of Germany will be visited, including the Krupp Iron Works, at Essen.

COMING MEETINGS.

ILLUMINATING ENGINEERING SOCIETY.—A joint meeting of Societies will be held at the Republican House, Milwaukee, Wis. Feb. 22, 1913.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum, Chicago, Feb. 26th to Mar. 8th.

ILLINOIS WATER SUPPLY ASSOCIATION.—The Fifth Annual Meeting of the Association will be held at the University of Illinois, Campaign-Urbana, Ill., March 11th and 12th, 1913. Secretary, Edward Bartow.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.—Annual Meeting will be held March, 3, 4 and 5, 1913, in the Green Room, Congress Hotel and Annex, Chicago, Ill. Secretary, Will P. Blair.

CANADIAN MINING INSTITUTE.—Annual Meeting will be held at Chateau Laurier, Ottawa, March 5th, 6th and 7th. H. Mortimer Lamb, Windsor Hotel, Montreal, Secretary.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill: Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James: Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson, Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C. Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. Mc Murchy; Secretary, Mr McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—P ident, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

PRECISE SURVEYS FOR MOUNT ROYAL TUNNEL

By J. L. BUSFIELD, B.Sc., A.C.G.I.

The Canadian Northern Railway have under construction a double-track tunnel about 3½ miles long through Mount Royal, on the west side of the city of Montreal. This tunnel is being built in order to bring the lines of railway from the east and west of Montreal right into the heart of the city, where a large terminal station is to be built.

The construction of a long tunnel usually means that very precise surveys and measurements have to be made as a preliminary step to the actual work of boring, and the Mount Royal tunnel is no exception to the general rule.

In driving a tunnel it is customary to work from both ends towards the centre, and in this case a shaft was sunk down to the level of the tunnel at an intermediate point and the tunnel is being driven both ways from this shaft, as well as from the ends. In order to insure that all these workings will correctly meet, it is essential that their locations with regard to each other should be very carefully established, both with regard to alignment and also for elevation and distance apart. To obtain the correct alignment, a line is, when possible, run on the surface in the same vertical plane as the tunnel, and precise transverses or triangulation must be resorted to for the distances. The necessity for accuracy will readily be understood on account of the fact that once the lines and levels are transferred into the tunnel no further check is obtained until the different workings meet.

Fig. 1.
Letting up Spider.

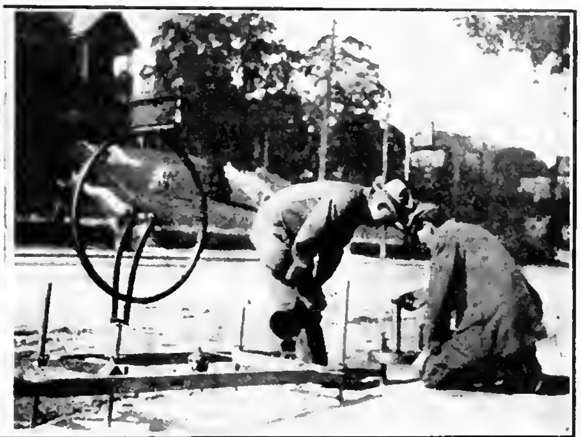

Fig. 2.
Chainman Reading Tape; Tension Wheel at Left.

On account of the steep and inaccessible slopes of the mountain it was deemed advisable to make transverse surveys around the side in order to obtain the exact distance from the east to the west portal, and also to the intermediate shaft at Maplewood Avenue. Suitable routes were selected and at all the angle points (called stations and given consecutive numbers for reference) small copper plugs were set into the sidewalks, or, in the few cases where there were no sidewalks, into the solid rock.

In order to make the transverse sufficiently accurate, the length of the route being about 4½ miles, it was necessary to adopt some form of base line measurement. The form decided upon as being eminently suitable for use on sidewalks and roads was that of portable measuring points called "spiders," used in conjunction with a steel tape supported at twenty-foot intervals, with a tension of twelve pounds applied by means of a weight attached to a cord passed over a bicycle wheel on an adjustable frame. These spiders are illustrated in Figs. 1 and 2, and weighed about sixty pounds each. The tension wheel is shown in Fig. 2.

Previous to making the precise measurements "spider" points were marked on the sidewalks by means of a chiselled cross roughly every ninety-nine feet on the lines of the transverse, being put in line between the angle points either by eye or with a transit. The necessity for exact alignment not being very great as an offset of 0.43 feet on either side of the line would only introduce an error of one thousandth of a foot in the length of the line. Where the lines were not on sidewalks, stakes or ship spikes were driven to mark the spider points. While these were being laid out by one party, a leveller would follow and take the elevations of all the spider points and enter them up in a book provided for that purpose.

In making the base line measurements 100-foot steel tapes were used of ¼-inch steel, divided into feet, tenths and hundredths, the thousandths being estimated by the observer. One steel tape was sent to the Bureau of Standards to be standardized under the same condition as the tapes were to be used under in the field, i.e., supported at 20-foot intervals with a tension of 12 lbs. It was compared with the government standard at a temperature of 62 degrees so all temperature corrections made later were to this figure.

All the tapes to be used in the base line measurements were compared with this standard tape. The standard tape and the one to be compared were fastened at the zero end to

two adjusting screws over a brass plate with a fine straight line on it; at the 100-foot end they were both attached to cords passing around two bicycle wheels with a twelve-pound weight attached to each. (See Fig. 3). The two 100-foot ends of the tapes rested on another brass plate with two scales on its face divided into thousandths of a foot; after the two zero ends had been placed exactly over the line on the first plate the readings on the scales at the other end were taken. The two tapes were then reversed and corresponding readings again taken. This process was repeated several times for each tape and an average taken.

All these preliminary arrangements being completed, the actual measuring was commenced, the method of procedure being as follows:—

First.—Two men would take the spiders and place them as nearly as possible with the cross marks vertically over the spider points. (Fig. 1). At the same time two other men would be setting up the tension wheel frame at a short distance to the rear of the rear spider. This frame is illustrated in Fig. 2, and needs no special description, except that it had adjustable legs and wheel so that it could always be put at the right height, even on the roughest ground encountered. At the front spider a forestay was set up to hold the front end of the tape. This forestay was simply a fairly heavy cast iron plate with a vertical post, upon which was a sliding clamp to which was attached an adjustable cord for holding the tape. A heavy weight was placed on the back of the plate to resist the pull of the 12-lb. tension weight.

Second.—The rear chainman would call out "Ready for tension" and thereupon the first chainman would attach the front end of the tape to the forestay and the rear chainman applies the tension of the weight by shortening the adjusting cord.

Third.—The rear chainman now stoops down until his eye is on the level and in line with the tops of the two spiders, and lines in the four wooden standards for supporting the tape at twenty feet intervals, so that the hooks are all in the same straight line between the tops of the spiders, and then the tape is hooked up into the hooks. The standards were made of a wooden base with a 1-inch-square vertical post with a sliding block held by a spring, a cord with a hook for holding the tape was hung from the block. A thermometer was also hung on each block in such a position that its bulb was as close to the tape as possible.

Fourth.—The chainman, having seen that there were no twists in the tape, they would take up their positions at the spiders, and the "recorder," who kept all the field notes, would take his position midway between them, calling out "ready to read" as soon as everybody had taken their place. On this signal the two chainmen would call out in turn the height of the top of the spider above the spider point on the ground which they measured with folding rules. This gave the correct elevations of the tops of the spiders, hence the slope of the tape. The head chainman then calls out the readings at his end of the tape at the intersection of the scratch on the spider, and the recorder enters it in his book, the rear chainman reads his end of the tape at the same instant as the head chainman, but does not call out until the recorder has had time to enter the first reading. The recorder then calls "change," and the tape is allowed to move bodily a very small amount one way or the other, so that a different reading is obtained at both ends, which are again called out to the recorder. This process is repeated until the recorder gets five or six readings which do not vary more than a thousandth or so. While this is being done another man is reading the four thermometers on the standards, the mean reading of which he gives to the recorder. The following is an example of the booking of one set of readings:—

Point.	Readings.	Difference.	Height of spiders.	Temp.
Line 14-15	99.478	99.151	Sp. 4 1.71	
	0.327			
Sp. 4 to 5	99.506	99.150		74.0°
	0.356			
	99.575	99.151		
	0.424			
	99.594	99.151	Sp. 5 1.69	
	0.443			

Fifth.—Having obtained a good series of readings, the recorder calls "unhook," and the tape is unhooked and the whole apparatus is moved forward to the next spider-point, the rear spider being left in its position to retain the measurement in case the one just measured to should be dis-

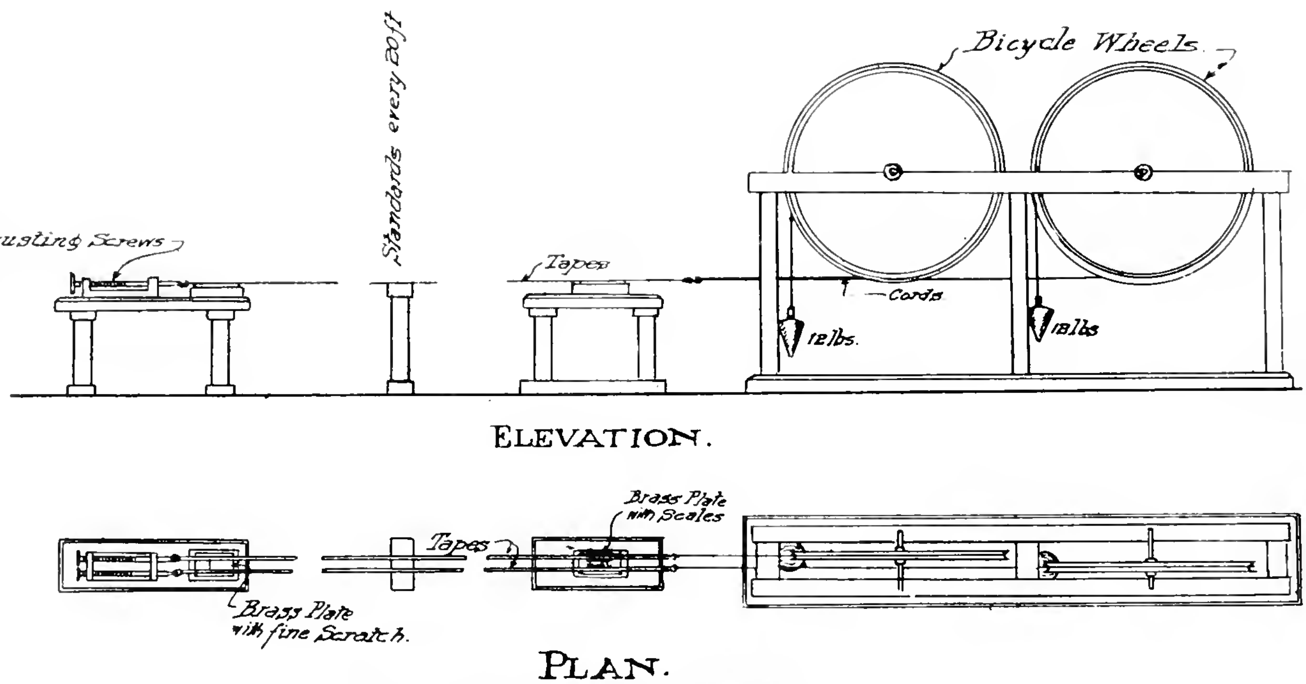

Fig. 3.—Sketch of Tape-Testing Apparatus.

turbed. Whilst the actual measuring is taking place two men carry up a spider and place it at the next spider point ahead.

At the starting point and all rivet stations, instead of one of the spiders being placed over the rivet it was placed a foot or two ahead merely as a support for the tape, and the reading on the tape was obtained by transferring the point on the rivet up to the tape by means of a transit placed a short distance away and at right angles to the tape.

This method of measuring required ten men, namely, chief of party, transitman, recorder, two chainmen, two spider-placers, one thermometer reader, one man for fore-stay and one man for tension wheel. Under favorable conditions as many as 15 to 18 stations were measured in an hour, but 10 stations per hour would make a good average for a day's work.

The majority of the work was done in the daytime but in the busy sections of the city it was done during the night, no difficulty being experienced from the darkness, acetylene miners' lamps being used.

Having made the measurements in the field, the correct distances between the stations were computed in the office, making the necessary corrections for the reduction of the distance to horizontal, for temperature, and the tape correction to standard, the two former being obtained from diagrams plotted for that purpose.

Great care had now to be taken in reading the angles of the transverse. A Berger transit, 7-inch plate reading to 10 seconds was used. In setting the instruments up over the angle points a second transit was used to insure the vertical axis of the instrument being exactly over the centre of the cross on the rivet. At the two points sighted at, wooden targets were used, being set up vertically and precisely over the points by means of a transit. These targets were made of wood 4 inches wide and about 3 feet high, and were divided into red and white triangles. Adjustable tripod legs were used to support them. In reading the angle one observer would read the angle once, and then wrap it up five times, and then go backwards until zero was reached again on sighting at the first target, to insure that the plates had not slipped. This would give a very close determination of the angle to 2 seconds, and this process was repeated by an independent observer, thus giving a mean determination down to 1 second. Every precaution was taken to eliminate any instrumental errors, and also to protect the instrument from the heat of the sun. In a circuit five miles long with 33 angles there was only an error of closure of 1 second, and in another of three miles and 10 angles the transverse closed exactly by the angles, and in none of the circuits was there an error of more than a few seconds. All the important transverses were duplicated by independent routes giving a complete series of closed transverses, and from the base line measurement an average degree of error was found to be about 1 in 40,000.

The measurements around the mountain being completed, it was necessary to project a line over the mountain in the same vertical plane as the tunnel centre line.

To do this the minimum number of transit points were selected and permanent concrete monuments built to hold the line. In setting up a transit at a monument plumb-bobs were discarded entirely and the transit was bucked into line until the cross hairs intersected both the far away back sight and also the cross scratched on the monument close to it. The line was then projected to the monument ahead time after time, reversing the instrument between each sight.

A mean was taken of all the points obtained at the foresight monument and the line thrown ahead from that point in the same way.

The surveys for the whole work were tied into the city system of base lines and a series of co-ordinate lines was adopted so that the latitude and departure of any point could be readily obtained, hence its distance and bearing from any other known point. All the survey alignment points in the tunnel are also being referred to the same co-ordinate lines. The levels were transferred from the city to the west portal in as accurate a way as possible with standard instruments; 18-inch wye levels were used with target rods. The level was set up three times for each turning point, these never being more than about 100 feet from the instrument and equidistant therefrom. The whole operation was repeated four times with independent observers. The difference in their elevations of corresponding bench marks being only a few thousandths of a foot.

In the city itself it was decided to put in permanent survey monuments at the more important and strategic stations. These monuments (Fig. 4) were made by digging a hole about 7½ feet deep and filling the bottom to a depth of about 2½ feet with concrete, in which was set the monument proper, made of 6-inch cast iron pipe at the bottom, with a 4-inch pipe inserted into it at the top with a leaded joint, the object of this being to enable the top of the pipe to be easily lowered again in case the whole pipe should be heaved by frost. This, of course, is an unexpected contingency. In the top of the smaller pipe a piece of brass was cemented and on this the precise cross scratch was made, and also the precise elevation taken. After the concrete had set, the space surrounding the pipe was rammed with earth or sand taken from the hole, and on top of this a cast iron cover plate and base set with concrete into the sidewalks was placed, thus making a good permanent point free from disturbance and easily accessible.

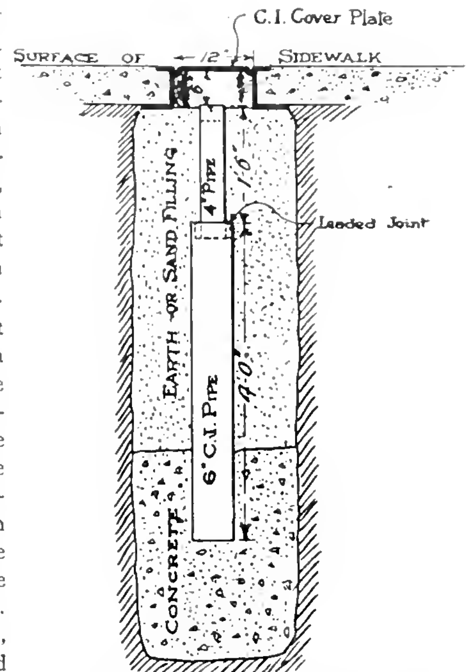

Fig. 4.—Permanent Monument for Tunnel Survey.

The surveys and measurements for the tunnel, which were all carried out under the immediate supervision of the writer, although requiring great accuracy, were comparatively simple, compared to the alignment work in the tunnel, because frequent checks on the work could be obtained, whereas in the tunnel no checks are obtainable until the headings are run into one.

The government owned telephone system of Alberta yielded a surplus of receipts over operation and maintenance expenses during 1912 of $62,283, while the earning capacity of the system on a basis of the capital expenditure amounted to 12.1 per cent. In the six years, 1907-1913, the system has yielded a profit of $407,592.

THE REPLACEMENT OF GASOLINE.

By H. Poynter Bell.*

The great and rapid increase in the price of gasoline is, not unnaturally, exercising the minds of the owners and users of gasoline motors all over the world. In New York, for instance, the price rose from 9 cents to 16 cents per gallon between January and July of last year, and the New York Garage Association is giving serious attention to ways of meeting the situation.

Two ways seem to have commended themselves. Firstly, the encouragement of competition in the sale of gasoline, and secondly, the establishment of a uniform standard of of quality, which may allow of increased production. The first way depends upon the suggestion that the increase of price is due, wholly or partly, to the action of the "Trust." There may be some truth in this, but it is certainly not the whole truth; the increase is largely, at any rate, due to ordinary economic causes.

Fifteen or twenty years ago the most important product of petroleum was kerosene; gasoline was merely a by-product and was used chiefly as a solvent. With the increased demand for gasoline, and a simultaneously decreased demand for kerosene, it is the latter which has become the by-product, with the consequence that the gasoline has now to bear the chief share of the cost of production.

At the same time, though the world's output of petroleum has increased, the yield of gasoline has not increased at anything like the same rate. There has been some falling off in the percentage of gasoline in the oil from the older oil fields, owing no doubt to evaporation, and the oil from the more recently opened fields is generally a heavier oil containing a lower percentage of gasoline. The crude oil from Pennsylvania contains about 16 per cent. of gasoline and liquids lighter than kerosene; the California crude oil contains not more than 3 per cent. of such liquids. The Russian (Baker) petroleum yields about 6 per cent. The resulting position of things is such that the producers, having too large supplies of kerosene, have felt obliged, in some cases, to refuse to sell gasoline to buyers who will not take a corresponding quantity of kerosene. It seems to follow that, under the circumstances, no great or long continued reduction of price can result from competition by rivals of the Standard Oil Company or other large producing organizations.

Rather more may perhaps be expected from the fixing of a legal standard for commercial gasoline. The production of so great a variety of motor spirits as is now sold must necessarily be more or less wasteful. If a liquid of fairly high specific gravity and boiling point could be made the standard, there would be an increased production from the present supply of crude oil, while there would be, at the same time, greater safety in the handling and storage of gasoline. To be of any real use, the standard would have to be fixed by law, and it may be doubted if this is likely to happen, since public safety is hardly concerned, as in the case of the flash point of kerosene.

In any case, measures of this kind can only give temporary relief and not permanent cure. Calculations of the duration of the world's supply of petroleum need hardly be taken into account. Such calculations have been made by Prof. Vivian Lewes, in England, and others; but apart from the fact that the quantity of the known supplies is very hard to estimate, no good guess can be made at the quantities which remain to be discovered. Assuming, however, that the demand for volatile liquid fuel continues to increase at the present rate, it will certainly exceed any increase of the supply which can reasonably be expected from the oil fields. That is to say, the users will, sooner or later, have to face not merely rising prices, but an actual shortage of supply.

The consumer of the future will, therefore, have to be resigned to paying more for his fuel, and must be satisfied if he can get it in such quantities as he wants. To produce even this result a liquid capable of replacing gasoline is likely to be needed, and for the production of such a liquid a prize of the value of $100,000 has recently been offered by the International Association of Automobile Clubs at their meeting in Paris.

The substance required is one which cannot be rigged or cornered by any nation or combination of national interests. It must, therefore, be capable of being produced in almost every part of the world, and must, further, be made from some raw material of which the supply is either practically unlimited or capable of being continually renewed. No fuel can be obtained from the atmosphere; no liquid fuel can be obtained from water, so that the only unlimited or renewable sources are animal and vegetable matter, of which only the latter is likely to be of much use. It may be that a method can be found of making, sufficiently cheaply, gasoline, or some similar liquid, direct from vegetable matter. At present there is one, and only one, liquid known which can fulfil the required conditions, that is, of course, alcohol.

Alcohol is suitable, in most respects, to replace gasoline, though its heating value is, unfortunately, considerably lower than that of gasoline. The value varies, of course, with the proportion of water which the alcohol contains, but pure alcohol has only about 7/11 of the calorific value of an equal weight, or about ⅔ of that of an equal volume of gasoline. That is to say, that to replace a gallon of gasoline there will be needed not less than 1½ gallons of alcohol. The disadvantage is not necessarily prohibitive, and it may be that consumers will have to put up with it. Alcohol can, of course, be produced in practically unlimited quantities, and at a low cost. The cost can certainly be reduced if a large enough demand arises, since little, if anything, has been done so far in the direction of selecting and cultivating plants with a view to a maximum yield of industrial alcohol. The matter will be one of the problems of utilizing the sun's heat for producing fuel which were indicated by Prof. Ciamician, of Bologna, in his lecture on the "Photochemistry of the Future," before the International Congress of Applied Chemistry, at New York.

The chief difficulty in connection with the use of alcohol will consist in reducing the restrictions and the excise and other duties, which are placed on the sale of alcohol by practically all governments. It will be for automobile associations and similar bodies to attack this side of the matter, while chemists may have to satisfy the requirements of the governments by finding substances which will render alcohol undrinkable.

Alcohol is, no doubt, not an ideal substitute for gasoline, but it appears that there may be only the choice between developing the production and use of alcohol and waiting, perhaps in vain, for the discovery of some better substitute.

*Consulting Technical Chemist, Kent Building, Toronto.

The English shipbuilding firm, Messrs. Swan, Hunter and Wigham Richardson, whose president, Mr. W. G. Hunter, is now in Montreal, will submit tenders for work on the Georgian Bay Canal, if that project is proceeded with, and for the construction of ships for the Hudson Bay line.

FISHING STATION SURVEY IN THE GULF OF ST. LAWRENCE.

By J. A. Macdonald.

The accompanying map and text is interesting from the viewpoint of the methods employed in making the survey.

The survey was made, among others, for a fish-canning company, who have in operation a hundred or more canneries, situated at various points on the shores of the Gulf St. Lawrence.

The company are continually establishing new fishing stations and closing others as business warrants.

Before establishing a station at any new point they usually have a careful survey made of the shore: shelter for boats, large or small, ownership of property rights, accessibility to a public road and railway, survey of the fishing grounds, showing distance from shore of the various depths of water, or "fathoms deep," and distance from shore or harbor of the various fishing grounds, as herring, lobster, salmon, etc. In order to obtain all this information requires an expert hydrographic survey of the harbor or cove, and this is really what this is.

In the map the methods of measuring the depths of water in order to be plotted are shown by the dotted lines.

Two methods of ascertaining the contour or fathom depths were used, involving the use of both the transit and sextant.

In the one case the angles were read by transits on the shore—two transits one at each end of the base line AB—and in the other case by reading the angles with a sextant in the boat on the water. This later method is known as the "Three Point Method."

Let A′ B′ C′ be the three shore points, being defined by the two distances A′ B′ and B′ C′ and the angle of B′. Let the two angles at P′ be measured at the point P′. The problem then is to find the distance A′ P′ and C′ P′.

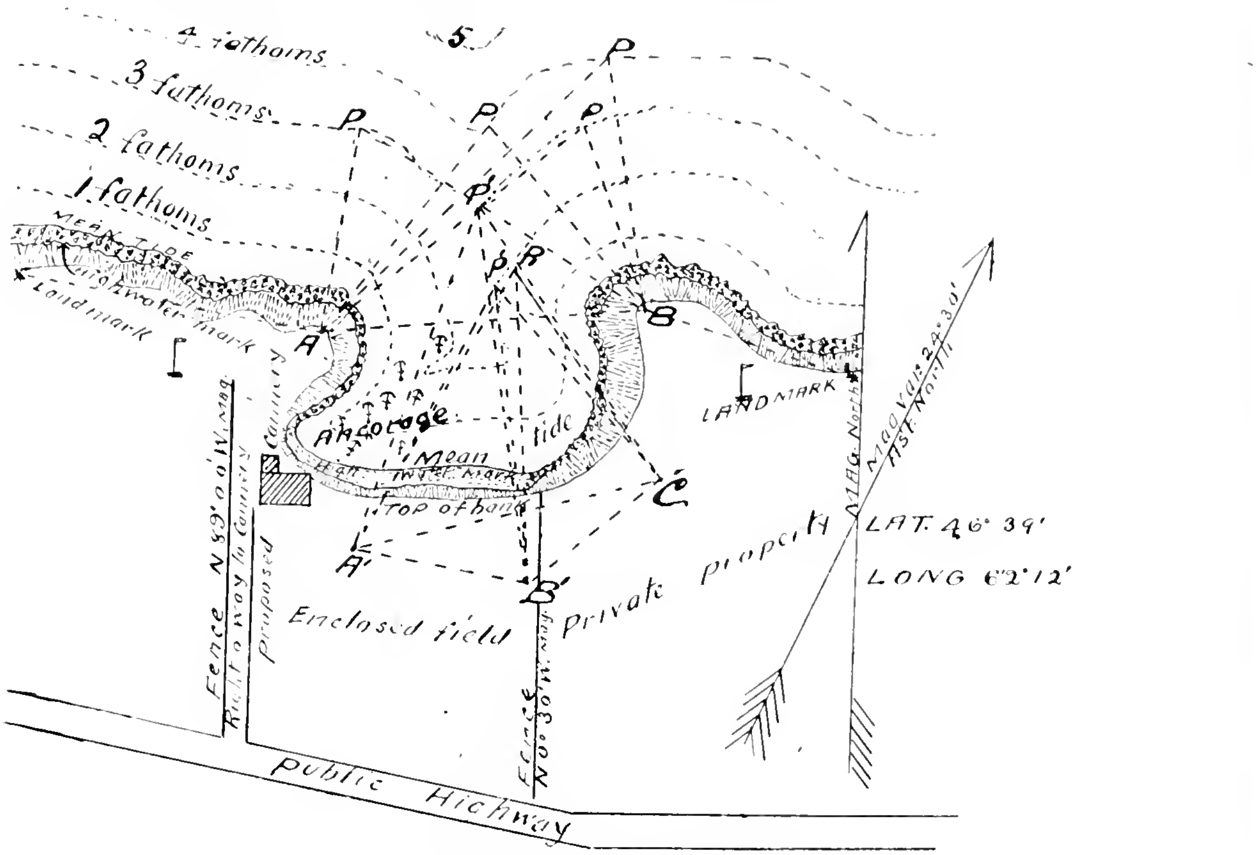
There is an analytical solution for this which, however, does not seldom need to have to be performed. It involves a good deal of figuring. The angles at P′ and the angle B′ are known, but the angles P′ A′ B′ and P′ C′ B′ are unknown. However, the formula gives:—

$$\cot. P'A'B' = \cot. R \left(\frac{A'B' \sin P'}{B'C' \sin P' \cos R} + 1\right),$$

$$\text{when } R = 360^\circ - B'P'C' + B'P'A' - A'B'C'.$$

I repeat that it is seldom necessary to use this analytical formula, though it is well to use it once in a while as a check, and should be used in all hydrographic surveys of this kind.

The so-called mechanical solution is simple and rapid by using a three-armed protractor. It is the common method of plotting soundings when two sextant angles have been read from the sounding boat.



Plan-Chart of Fishing Station in Gulf of St. Lawrence.

The angles in this case were laid off graphically on tracing paper by lines of indefinite length, and this laid on the plot and shifted in position until the three radial lines coincide with the three stations on the ground, A′ B′ and C′, when their intersection marks the point, P′, of observation. This is a most ready method of plotting such observations when no three-armed protractor is available.

By this method only one observer is required in locating the soundings, and no time is lost in changing stations, and the party are all together, and there is not likely to be any misunderstandings in regard to the work.

The other method here shown, two angles read on shore, two instruments are required, one at A and one at B on shore, and the angles subtended by the other fixed point and the boat P, as A B P and B A P, be read by both instruments. When a sounding is taken, the intersection of

the two pointings to the boat, when plotted on the chart containing the points of observation duly plotted, will be the plotted position of the sounding.

Two observers are required, which makes this method somewhat objectionable, and these must be transferred at intervals as the work proceeds, and in order to see the boat, P, at all times. Usually, three or more readings can be made from each position. For example, in the plot four positions of the boat at P are taken.

The base, A B, across the bay, was made by a stadia reading. The transit was set up at A and the rod held at B. Two other base lines were also laid off, as shown in the dotted lines, one from A westerly to point shown as landmark, and the other from B easterly to "landmark. For the three-point readings flagpoles were erected about the centre of the base lines and to the south in the same manner as A' B' C' in the plot. These are shown in the plot.

The shore line was first traversed at the water's edge. Offsets to the bank were estimated, and sometimes paced; no measuring was done. The first part westerly was rocky, with high, steep banks. Along the cove, or natural harbor, there was a sandy beach, with low banks. Around the point, again, it was rocky, with high cliffs. This is shown by the topography on the chart. The direction of the land lines, width, and property-owners were made, taking bearings with the compass. Direction and position of roads were determined, and everything necessary to complete the plot and give all the information required.

The cove or harbor was a natural one. A wharf could be built, and was later, below the cannery, making it convenient for landing fish. The anchorage was good for boats and small craft, and perfectly safe, except with north-east winds. The harbor was well sheltered from south, west and north-west, and these were the prevailing winds. A north-east storm would, however, drive right in to the harbor, and no craft could live at anchor in such a storm. With regard to the smaller craft, provision was made for hauling them up on the sand beach in the rare times of such storms. Larger craft would either have to ride it out or get away in good time.

The soundings in the boat were taken with lead and line marked in fathoms. At even fathoms positions were taken and the triangulations made either with sextant from the boat or with transit or compass from shore.

In plotting those soundings no calculations were needed. The intersections of the two or the three points showed the position of the boat at one fathom, two fathoms, etc.

The soundings in the harbor were mostly made by using a long 30-fathom marked line for distance, and the bearings from a known point on shore were made with a prismatic compass. No one method answers for this kind of work. One has to have a certain amount of initiative or originality in this kind of work.

Latitude and longitude were ascertained, the former by a reading of the sun's altitude with the sextant at apparent noon, and allowing for dip, semi-diameter, paralex, etc. The sextant is much more convenient and accurate for taking astronomical observations than is the transit. Longitude was calculated from the ascertained longitude of a lighthouse some twenty miles distant, assuming, of course, that the longitude of the lighthouse was correct. The magnetic declination was ascertained by an azimuth observation of the sun.

Surveys of this nature are very rare, and confined to marine and fisheries in Canada and to the coast and geodetic surveys in the States. In the building of breakwaters and harbor improvements by the Public Works Department such hydrographic surveys are always made. It is, therefore, confined largely to Government work, though in the case here described it was of a private nature.

ORGANIZATION OF A STATE HIGHWAY DEPARTMENT.*

By Maj. W. W. Crosby.†

The essentials for a successful state highway department may be said to be:—

1. An established demand for it.
2. A proper organization of it.
3. Sufficient funds for its work.
4. A well defined policy.
5. An honest, tactful, capable head.
6. Suitable locations for its headquarters and branches, proper equipment, and loyal and skilled employees.
7. Perfection in designs for its work and efficient execution of such designs.
8. A comprehensive system of accounting from which intelligible public reports are regularly made.

The title of this paper, and, as I understand, its purpose, confine the speaker to the second essential except as reference may seem necessary to one or more of the others, and such will be his effort.

From the speaker's experience, he believes that the subject of the organization of a state highway department should be viewed from two points. First, from the point of establishing such a department as will most likely succeed in acquiring for itself and for the movement for better roads sufficient stability to endure, and, second, from the point of view, after such a stage has been reached and public support both moral and financial assured, of then increasing its efficiency.

Now for the stable upbuilding of a state highway department, the speaker believes a state commission of three is best. Five are ordinarily unnecessary and less likely to form a facile and mobile unit. They are likely to separate into five units and not to amalgamate into one uniform and homogeneous body, and this lack of unity will surely produce rivalries and schisms.

One commissioner, on the other hand, is ordinarily weak in a number of points. The selection of one man with the necessary tact, honesty, and executive ability, and, at the same time, possessed of either the proper engineering skill or the recognition of his lack of it and with the breadth to acknowledge such lack by the employment of a skilled engineer assistant, is a most difficult task to set any appointing power. Further, with "but one neck to be lopped," a single-headed commission is far more susceptible to the temptations of politics and to the attacks of enemies. The demands of questions of policy, of law, of administration, of execution, and of engineering are too great and diverse to be satisfactorily and permanently met by more than one man in a thousand and the chances for the appointment of that man in any case are probably not one in one hundred when the various influences concerning such appointments, the salary likely to be offered, and all the other factors are considered. With a commission of three, properly selecting and protecting its engineer, the latter can do the public, his board, his subordinates and himself, much more nearly actual justice than if he is obliged to act as both commissioner and engineer.

Under any commission there should be employed a trained and competent chief engineer. Probably the commission will also need to employ a secretary and certain book-

* From a paper read before ninth annual convention of American Road Builders' Association, held at Cincinnati, December, 1912.

† Chief Engineer, Maryland Geological Survey.

keepers, clerks and stenographers reporting to and under the authority of the secretary. Legal counsel may be generally advisable and should report directly to the board or its chairman. A right of way agent may be necessary and he may report to the counsel or to the secretary, as deemed advisable. The chief engineer should be the chief executive officer of the board, and he should be given all the authority necessary to make this fact fully and finally realized. As such, his responsibility to the board would be definite and the board should do nothing to muddy the waters of this situation.

The speaker wishes to say here that it seems to him that more inefficiency, with its waste of money and unsatisfactory results, has come from division or lack of clearness in responsibility than from incompetence.

In such a position as above described, a chief engineer can not only afford to be perfectly open and frank in expressing his opinions to his board, but he is encouraged to do so to the extremes of his ability. The board may then act more intelligently. In cases, where in its opinion the other considerations outweigh the engineering ones and the decision seems to be against the recommendations of the chief engineer, the latter feels his relief from the responsibility, and his efforts to properly carry out the decision of the board should, and probably will, be more earnest and effective.

Under the chief engineer should be two assistant engineers selected by him—as, it might be said here once and for all, should all the employees of the engineering department. One should be in charge of the construction, the other of the surveying and planning. But the plans should always go up to the chief engineer through the assistant in charge of construction. The benefit of criticisms from the workers in the field will then be had before it is too late to make changes without complications or serious expense and many of the routine difficulties of execution will thus be avoided.

As soon as the completed construction has reached an aggregate to justify it, the establishment of a maintenance division and the selection of an assistant engineer for its head should be had. Preferably this important step should be taken before it is clearly justified, rather than after.

The vast importance of proper maintenance of roads is beginning at last to be recognized by the states. One, at least, of the reasons for the better maintenance of European roads is unquestionably the absence, to a great extent, from the minds of those in authority over the roads there, of construction problems and consequently the concentration there possible on the minute, tedious, and recurrent details of maintenance. The proper solution of construction problems is not only of interest to almost all, but is also generally accompanied by early and shining rewards. That of the maintenance problem seldom, if ever, is quick or spectacular. Naturally construction problems attract, while those of maintenance seem drudgery. Long, persistent effort in little ordinary matters is demanded of the maintenance division. No greater mistake can, in the speaker's opinion, be made than to expect the maintenance to be satisfactory where the engineer in charge of construction is required to look after it also. This holds good surely above the point when the maintenance expenditures are up to 10 per cent. of its construction expenditures annually.

Division engineers, resident engineers and inspectors will be arranged and needed according to the territory to be covered and the amount of work going on. Probably also, facilities for testing materials will have to be provided and the man in charge of such should report to the head of the construction of maintenance division according to the amount of work being done for each by him; or, he may report to both under some circumstances.

Under the assistant in charge of the surveying and planning will be needed one or more survey parties, draftsmen, calculators, etc., the number of each depending on circumstances, as may readily be seen.

If the amount of work to be done annually is large, scattered and complex, the chief engineer will also need clerical assistance in the shape of a chief clerk or secretary, possibly a purchasing agent for materials for force account work, clerks and stenographers. The purchasing agent may report to the assistant in charge of construction or to the chief engineer directly, as deemed best. The chief clerk should report to the chief engineer directly and the clerks and stenographers to the chief clerk.

The responsibility for the entire engineering department resting clearly on the chief engineer, should be delegated by him only as may be warranted by the exigencies of the situation, and when so delegated, it should be done so clearly and definitely that there can be no doubt nor failure in the mind of anyone having business with the organization in understanding just what authority the subordinates have, at least so far as it concerns their business. There should be left no opportunity for a contractor to say that certain work or materials should be paid for in full "because the inspector or resident engineer saw it go in," nor should a contractor be able to say he was referred from one party to another for a decision on a point and, unable to get anything definite, he "had to do the best he could."

The delegation of authority, especially in a newly organized state highway department, must be made conservatively. The commission and its chief engineer may be new to the work or to the situation, even if the engineer has been trained in similar work elsewhere. Naturally the public will look to them personally for decisions and for locating responsibility, and at first surely demand their personal, physical presence in many cases. The customary requirement for the employment as far as possible of local men for the subordinate positions, at least, will render it advisable for the chief engineer to take on many bright and otherwise admirable young men except that they may be deficient in experience with modern highway work.

The rapid progress in the underlying science and the art of such work, makes it difficult for many beside the chief engineer to keep up-to-date in it, and, therefore, necessary for him to retain, until his subordinates become fully trained as regards the fundamentals of their work at least, sufficient authority, in perhaps a slight excess, for the best results. Further, the speaker has found that far less difficulties with contractors over points arising in connection with their work under the specifications become serious when considered and decided by the chief engineer in person than in cases where such decisions are left to younger and more inexperienced men. In fact many of these points are never raised when contractors know that the chief engineer himself will decide them and can be counted on to abide fairly by the specifications. Of course, unless the commission leaves the decisions provided by the contracts to be made by the chief engineer in the hands of the latter, and supports him in such, those contractors or others anxious to have their claims arbitrated by inexperienced or prejudiced parties may create, by appealing to the commission for decisions, an even worse situation than that in which the authority of the chief engineer's subordinates is not clearly defined or too much delegation of authority has been made to them. But relief from such a situation is from outside the remedies of organization.

From the foregoing may be had an explanation of the speaker's inclination toward the employment in new organizations of inspectors rather than resident engineers on the jobs to be done under him as well as for the retention in his own hands, while chief engineer, or perhaps more of his authority, as such, than in the similar work of many other organizations.

After the final establishment of a definite policy towards its roads on the part of a state; after the proper provision of funds for the carrying out of this policy for at least a reasonably appreciable time; after the public has become accustomed to and a decent majority has settled down to the support of such a policy, and after the employees in the organization, who are likely to perhaps need authority, have become properly grounded and trained to support satisfactorily certain responsibility, then a change or development of the organization above outlined may be, and generally is, desirable for the sake of greater efficiency in the results from expenditures.

We may, therefore, now look at the matter of the organization of a state highway department from the second point suggested at the outset.

Efficiency should, of course, be kept in mind as described in the earlier consideration, but there as may have been hinted at least, it was not the only object, and consequently in the earlier days of the work, the efficiency from a purely financial standpoint may have been obliged to retire at times in favor of what seemed to be for the ultimate public good.

Now considering efficiency alone, the speaker believes that:—

The commission of three may well give way to that of one, or even in the latter case that a competent individual may satisfactorily fill such a position as engineer-commissioner, and the position of chief engineer, as well as the board of commissioners, be avoided. That the position of assistant engineer in charge of surveying and planning may, perhaps, with the central department for his work, be abolished and the work better done under the division engineers assigned to sections of the state. This, however depends entirely upon local conditions and no general rule can be here laid down concerning the point. That it is possible to say the same concerning the assistant engineers respectively in charge of construction and of maintenance, as said immediately above; but in such a case, the necessity for avoiding any serious distraction from maintenance problems by those of construction, should be clearly and constantly kept in mind. That the delegation of more and more of the authority of the chief engineer may be advisable as the training of the subordinates proceeds and the reliance on them is warranted.

With these steps taken at the proper time, the expense for overhead charges should be reduced without depreciation in the value of the physical results and thus the efficiency of the organization increased. Inappropriately taken, they will quickly produce the opposite results on a large scale. The difference between a proper organization and an improper one may be only five per cent. of the total expenditures in the work and this difference can be readily offset many times by the difference in the quality of the physical results, the expenditures for which will probably amount to nearly 90 per cent. of the total expenditures.

The necessity for the proper organization of a state highway department should be recognized by all, but unfortunately the instances of such recognition, or at least the evidence by results of it, seem to be in the minority.

The speaker hopes that the discussion here of the matter, which discussion he has attempted to stimulate by a brief outline of some of his views, may be fruitful in good results.

SLUDGE DISPOSAL.*

By Karl Imhoff.†

Sludge results from all methods of treating sewage. The problem of handling this sludge satisfactorily is just as important as the treatment of the sewage itself, for experience has shown that sludge which has been poorly handled is much more objectionable than the worst sewage.

Wet Sludge.—Fresh wet sludge contains ordinarily more than 90 per cent. water and can be pumped out of the settling tanks in the same way as sewage or water. It would therefore seem a simple matter to get rid of it by pumping it onto low-lying ground and allowing it to remain there with the hope that it would in time become firm. Such treatment is unfortunately almost always without success. Sludge deposited in deep lays does not dry, and the ground remains wet. This treatment is therefore useful only when the sludge is spread out in very thin layers. The sludge can also be discharged into shallow trenches. Under these conditions the sludge dries in some weeks, and can be plowed into the ground for agricultural purposes. The sludge thus becomes used, as it were, for irrigation, just as with sewage. There is the disadvantage, however, that a large area is necessary, and that objectionable odors cannot be prevented.

In the case of cities located near the ocean, the problem becomes simpler. Such cities can send their sludge in ships out to sea and allow it to sink. Since it becomes necessary to carry the sludge a considerable distance from the shore, the cost of this method of disposal is quite high, and it is very probable that some of the cities which have been using this method of sludge disposal could now accomplish the desired ends cheaper by adopting another method of disposal.

In general, one can say with assurance that the cases are very few where it is desirable to dispose of sludge in a wet condition.

Dry Sludge.—As soon as sludge has been properly dried, it has lost most of its objectionable characteristics. In any case, dry sludge can be used as easily for agricultural purposes as other kinds of fertilizer. Its value, however, for agricultural purposes depends more on its physical characteristics than on its fertilizing value.

Dry sludge can also be used for filling low land just as well as ordinary earth. In almost every case this method of disposal is the most economical, if it is not possible to use it for agricultural purposes. Especially with cities which use their refuse for filling is this method of sludge disposal particularly adaptable, because the dry sludge has a volume only about one-fifth of that of the city refuse, and if a city has sufficient ground for dumping its refuse, there will also be sufficient area for the sludge.

In cities where the refuse is burned, consideration should be given to the possibility of burning the dry sludge with the refuse. In such an event, however, there is the danger that the slag will not be so good. In addition to the incineration of sludge, it is not worth considering other methods of artificial disposal of dry sludge; such, for example, as using it for the production of gas or for the reclaiming of the fat contained in it.

As incineration is carried out on a large scale only in one instance (Frankfurt-am-Main) it may be concluded that for the disposal of dry sludge there are left only the two

*A paper read before the International Congress on Hygiene and Demography, Washington, D.C., Sept. 24, 1912.

†Chief Engineer, Sewer Department, Emscher, Genossenschaft, Essen, Germany.

natural methods—its use for agricultural purposes and for the filling of low land.

Methods of Drying.—From what has already been said, we may conclude that the best system of sludge disposal is that in which the sludge is first dried. There are, of course, difficulties connected with this drying.

Science has, up to the present time, interested itself principally in artificial methods of drying. Of first importance in this connection is the pressing of sludge, which has been used for many years in England. The excess water in the sludge is pressed out through filter cloths. Sewage sludge can be pressed only when it is properly treated, for example, with lime or coal powder. This system is a good one, and for the foregoing reason is especially applicable to chemical precipitation works, where the chemicals necessary for the precipitation are added to the sewage. The cost of the system is, however, so high, that, outside of England, it has been used very little.

In comparison with sludge pressing, the centrifugal drying machines used in Germany (Frankfurt and Hanover), are a step in advance, since the fresh sludge is handled without the addition of chemicals. There is, however, the serious disadvantage that the water separated from the sludge is much more objectionable than in the case of sludge pressing. This water contains a very large part of the organic matter of the sludge.

A more natural treatment, and one especially applicable for small plants, is the mixing of the wet sludge with drying matter, which absorbs the moisture. Refuse and street cleanings are especially applicable for this purpose if the sludge is to be used for agricultural purposes.

The simplest of all methods of drying is just to discharge the sludge upon a drying bed, which should consist of 10 in. of porous material with a perfectly horizontal surface, and underlaid with drain pipes laid approximately 12 ft. c. to c. It must not be forgotten that there should be spread over the surface of the bed a thin layer of fine sand, which will have to be frequently renewed.

This simple natural arrangement for drying was formerly very little used, because all attempts to drain fresh sludge were unsuccessful. The sludge must first be made drainable. Without question, this can be done by artificial means, as with the addition of lime or coal powder, in the same way as with sludge pressing. But all these methods of drying are uneconomical.

Automatically, by itself, the sludge becomes drainable while undergoing a process or natural decomposition. We have known this fact for a long time from the "septic tanks," through which the sewage slowly flows, and as a result of being in contact with the decomposing sludge, becomes foul itself and smells. In comparison with these septic tanks, a step in advance was made by separating the decomposing sludge from the flowing sewage, by removing it into a separate tank.

This idea of separate sludge decomposition was, so far as I know, first brought forward by H. W. Clark, of Boston, in the year 1899. It was not possible, however, in the experiments made by Mr. Clark, as well as in other places, to effect, in a separate sludge tank as good a decomposition as with the ordinary septic tanks.

The first success along these lines was made in the year 1906 at the sewage-disposal works of the Emschergenossenschaft in Essen. The type of works referred to are spoken of as Emscher tanks, a special type of double-deck tanks, which consist of an ordinary settling chamber and a sludge-decomposition chamber below, through which there is no flow.

After a short ripening time, there was found in these sludge-decomposing chambers a sludge black in color, and with a slight ordor of tar. In spite of small water content, ordinarily of about 75 per cent., the sludge flowed easily through pipes, and when spread upon a drying bed to a depth of 10 in., became firm and spadeable in a few days. The decomposition was practically odorless, and the sewage flowing out of the settling chamber was totally unaffected by the decomposition of the sludge.

Since we know that it is possible with separate sludge chambers to have the principal advantage of the septic tank, namely, the drainability of the sludge, the septic tanks have lost their importance. Their disadvantages, especially the objectionable odor of the effluent, render them impossible for many purposes. They are to-day suitable only for very small plants.

In most cases, it is desirable to keep the sewage fresh; in other words, to treat it in ordinary settling chambers, and to remove into a separate chamber only the sludge, which requires decomposition, in order that it can be easily drained and dried. It is not to be assumed that the Emscher tank is the only arrangement for bringing about these results. It is possible, without question, to bring about the natural decomposition, which takes place in Emscher tanks, with any properly built tank, filled in the right way with sludge, and operated according to certain principles. I do not yet know of any plants with separate sludge tanks, however, where exactly these results have been obtained. And it seems to me as if all possible scientific methods of bringing about these results, with plants in which the sludge is pumped from the settling tanks to special decomposition tanks, will be much more expensive both for construction and operation.

Practical Tests of Sludge.—In the sense of what has been said, good sludge may be considered as sludge which dries quickly and has no objectionable odor. The following information shows the possibility of easily determining the character of sludge.

Appearance and Odor.—Good sludge is black, and uniformly granular. It moves easily, it has a slight odor of tar or burnt rubber. Bad sludge is grey, full of fibres, soapy, sticky, and has a bad odor.

Adhesiveness.—A white enamel-lined dish pan is filled with sludge and then emptied so that only enough sludge remains to just cover the surface of the enamel. Good sludge will separate itself at once from the water, so that in 10 or 15 sec. the surface is broken up by white lines. Bad sludge sticks to the entire surface. This experiment is especially important because it gives the information at once.

Gas Content.—Newly withdrawn sludge is placed in a measuring glass to a height of 1 ft. After six hours good sludge separates itself from the water which collects below the sludge. With bad sludge, the water collects on top.

Drainability.—Sludge is placed on a sand filter to a depth of 10 in. In the case of good sludge, considerable clear water will drain out in the first few hours. In three days, during dry weather, it will be firm and spadeable. With bad sludge, only a small amount of water drains out of the sludge, and this takes place very slowly.

Conclusions.—The two best methods of disposal of sludge are (1) its use for agricultural purposes, and especially (2) filling of low land. In both cases, the sludge must first be dried, and this is best effected upon a drying bed after the sludge has decomposed in an inoffensive odorless manner in a separate tank through which sewage does not flow.

GAS-ENGINE RESEARCH.

On Thursday, January 30th, Professor B. Hopkinson delivered a lecture at the Royal Institution, London, England, on "Recent Research on the Gas-Engine." In his opening remarks Professor Hopkinson pointed out that during the last thirty years, though expectations had been realized with regard to the economy secured in the gas-engine as compared with the steam engine, as regards development in the way of size, anticipations had not been realized owing to limiting factors which were not foreseen many years ago. The Selandia had engines of 2,500 horse-power, but that was developed in sixteen small cylinders. On that scale large modern vessels would require from 200 to 250 cylinders, which was altogether out of the question. The rapid progress made by the steam turbine, which was now being made in 40,000 horse-power units, was in great contrast to the development of the gas-engine, which engineers found to be hampered by serious difficulties. It was the province of engineering science to investigate such conditions as these, and it was to the credit of this country that it had contributed largely to the advance in gas-engine research in recent years. That had largely been the result of the work of the British Association Committee on Gaseous Explosions.

In order to explain the nature of the difficulties encountered, Professor Hopkinson described the ordinary gas-engine cycle, and pointed out how, in it, waste might be saved by increasing the expansion. In order that that might be accomplished, it was necessary to compress to a greater extent, with resultant increase of pressures on firing. That, however, necessitated a much more heavily built engine. The flame of gas in the cylinder parted with its heat at a great rate, and the metal had to be kept reasonably cool to ensure satisfactory working. In order to demonstrate what went on inside a gas-engine cylinder Professor Hopkinson fired, inside a closed vessel provided with a glass window, a mixture of gas and air identical with that consumed in a Bunsen burner. Whereas the Bunsen flame was practically non-luminous, the flame in the closed vessel was seen to be luminous. The pressure in the vessel rose rapidly and fell off quickly, but more slowly than it rose.

To determine the extent of the heat-flow to the walls of a vessel in which an explosion took place, a vessel lined with a continuous spiral of insulated copper strip had been employed, and the varying electrical resistance of the strip of copper had been recorded, the pressures resulting from the explosion being recorded simultaneously. The heat-flow was found to be about 10 calories per sq. cm. per second, which was about the rate of radiation from molten steel. That flow of heat caused the chief troubles in the gas-engine. To deal with it the water-spaces had to be exceedingly large compared with the working space, while they were also extremely complicated. The exigencies of design further rendered a uniform heat-flow an impossibility, so that some parts were much hotter than others, with the result that bad stresses were set up, and castings often broken. Although large differences of temperature were thus most undesirable, they were essential to the maintenance of the necessary heat-flow. Unless this was sustained some part might become sufficiently hot to ignite the gas prematurely.

Till recently it was imagined that the heat-flow was due chiefly to convection and conduction. It had now been shown to be greatly due to radiation. Gaseous molecules were in constant vibration, and when, in the combustion of the gas mixture, chemical combinations took place, the vibrations were intensified, with resulting increase of radiation. Explosion experiments had been made in closed vessels with black interiors, absorbing radiant heat, and again in vessels polished inside. The effect in the latter case was to retard the heat-flow, and consequently the rate at which the pressure fell. Cooling was roughly only two-thirds as fast with the polished as with the black surface. Radiation during combustion had been measured by a platinum grid placed outside a fluorite window in the wall of a closed vessel, and it was found that about half the heat of combustion in the vessel was radiant heat. As the volume increased the radiant heat increased. That had been proved by David, who got twice the amount of radiation at the window of a vessel polished inside that he did when black, the polishing being equivalent to an enlargement of the volume.

The difficulties were, therefore, cumulative as regards large gas-engines. In the larger sizes, owing to the increased dimensions, large differences of temperature were necessary in the castings, in order that the heat-flow should be sustained; and as the increase of the volume of the flame added further to the heat to be dealt with, still greater temperature differences had to be employed.

MEXICO'S OIL PRODUCTION.

The oil industry is rapidly developing in Mexico, and this has now begun to assume proportions of such magnitude and is destined to be so far-reaching in its effects on the world's commerce generally that it is worthy of closer attention.

The total investment in this industry is now upwards of $80,000,000 gold, and its development has practically all taken place within the last five or six years. Broadly speaking, the petroliferous zone has been found to extend for 250 miles along the Gulf coast and fifty miles inland (12,500 square miles), with the port of Tampico near the centre. The present production (though many wells have been closed after testing, pending the development of transportation facilities) is conservatively stated at 214,000 barrels, of forty-two gallons each, per diem. Not 10 per cent. of the wells drilled have failed to show oil, and the average yield per well is 2,000 barrels per day, as against 42.56 barrels in California, which is the largest of the United States oil fields. It is true that the average yield is greatly increased by the production of a few very large wells, but these latter are situated many miles apart with innumerable "strikes" between, so that this average will probably be maintained as development progresses.

The world's total production in 1911 was 345,000,000 barrels of forty-two gallons, or 53,000,000 tons. The present potential production in Mexico is 78,110,000 barrels, and this from not more than a hundred wells. According to the latest figures to hand, Mexico has jumped from a production of 1.02 per cent. of the word's total in 1910 to a potential production during the present year equal to over 22½ per cent. of the total for 1911. This is second only to that of the United States and 8,000,000 barrels more than Russia produced in 1910. In accomplishing this less than 1 per cent. of the proven oil area has been prospected, and the country has only to increase its production threefold to become the largest producer in the world, a position which, with the same success as has been experienced in the past two years, she may very speedily attain, and even then not have tapped one-twentieth of her petroliferous zone.

The chief difficulty in the way of this development lies in the lack of transportation facilities. The total number of oil tankers registered at Lloyds is below three hundred, whereas, allowing for the present ratio of increase, it is estimated that it will soon take three times that number to transport the oil supply of the Gulf coast alone. In anticipation of this most of the shipyards in Europe are congested with tankers under construction.

CALCULATIONS FOR THE CAREENING OF A CAISSON.

By Leonard Goodday, C.E., M.E.*

The caisson, as illustrated in the diagram below, was constructed a few years back for the entrance to a "dock basin" in the east.

A caisson, as with any vessel, has to be built with great accuracy, so that when its keel is horizontal the vertical planes, both longitudinally and transversely, are square to one another, i.e., the vertical plane through the centre line from stem to stern is at right angles to the vertical plane athwart the beam when it is in equilibrium as a floating body. This is so when its centre of gravity is in the same vertical line with the centre of gravity of the fluid displaced. When it careens or gives a list to leeward from any external pressure, these centres of gravity alter their position, and if a vertical line is drawn through that of the fluid displaced until it meets the axis of the body, then that point will be the meta-centre of this body. Stability is always maintained when the meta-centre is above the centre of gravity, and unstable if below.

When being moved from the "Chamber" or any other place to the entrance, a caisson is liable to encounter fresh winds, and it has been known to have too much of a list, which makes it very troublesome to place in position. The hydrostatic pressure will assist in making it come to its bearings when in place, when the water is being let in for sinking it.

These conditions being fulfilled, an approximate calculation is made before the construction takes place to determine the wind pressure required to careen the caisson to an angle, causing the flood openings to be just awash.

Now, by calculation and measurement, the angle in this case will be $1^\circ\ 15'$ to the vertical.

Height of meta-centre above the centre of buoyancy (C.B.) equals moment of inertia (M.I.) of water plane $58' \times 23'$ divided by the displacement in cubic feet equals

$$\frac{\text{Length} \times \text{Beam}^3}{12} \div 454 \text{ tons} \times 35$$

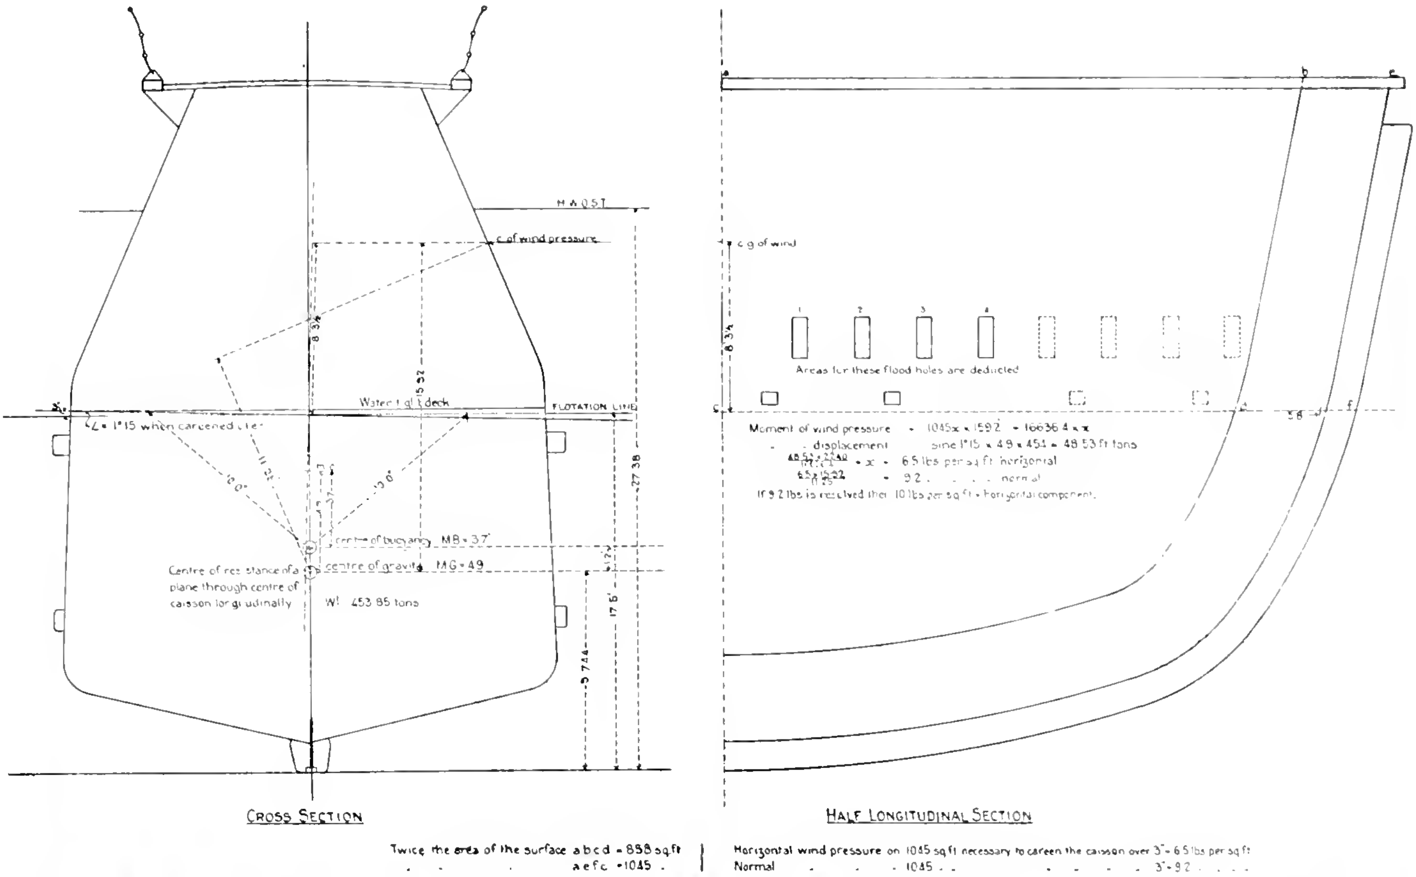
$$(35 \text{ cu. ft.} = 1 \text{ ton sea water}) = \frac{58 \times 23^3}{12 \times 454 \times 35} = 3.7 \text{ M.B.}$$

Height of C.B. above C.G. $= 1.2$ ft.

Height of meta-centre above C.G. $= 4.9$ M.G.

Height of centre of wind pressure (when horizontal) above the centre of resistance $= 15.92'$

Moment of wind pressure $= 1{,}045$ sq. ft. $\times\ 15.92' = 16636.4$



Caisson at Basin Entrance at Dockyard—Diagram Showing Wind Pressure Necessary to Careen Caisson Over 3 Inches.

The righting moment at an angle of $1^\circ\ 15' = \sin 1^\circ\ 15' \times$ M.G. $\times$ displacement $= .0218149 \times 4.9 \times 454 =$ 48.53 ft.-tons A

Total pressure of wind on the side of the caisson to balance A $= 16636.4 \times x$ (when x = pressure per sq. ft.)

Therefore, the horizontal pressure of wind necessary to careen the caisson $1^\circ\ 15' = x = \dfrac{48.53 \times 2240}{16636.4} = 6.5$ lbs. per sq. ft.

If normal, the pressure becomes $\dfrac{6.5 \times 15.92}{11.25}$ (11.25 being the leverage of wind $= 9.2$ lbs. per sq. ft.

* Late of the British Admiralty.

If 9.2 is resolved, the horizontal compound = 10.0 lbs. approximately.

According to Molesworth, this nearly equals a very high wind, which would be from 7.8 to 9.9 lbs. per sq. ft.

Under these conditions the caisson will practically remain in equilibrium under all conditions of weather.

BUILDING GRADES AS GIVEN BY THE CITY OF EDMONTON.

By C. C. Sutherland.*

In Edmonton, as in other cities, we find people building in advance of local improvements, and in order that their door-steps and lawns may coincide with the finished street, it is necessary for the City Engineer to give each builder the elevations at which the future improvements will be constructed.

With these elevations marked on grade stakes at the front of his lot, the builder is then in a position to construct his house and finish off the lawn and sidewalks at the proper elevation to fit in with the completed street.

It is of great importance, then, having once given the grade to the builder, that this grade is not changed, and that future construction will go in at the elevations given, and not above or below the improvements made by the builder.

In a municipal office where the grades on a street may be established by one person and set in the field by a second, while with a continually changing staff of engineers, the construction of the permanent improvements on a street may be laid out by a third man, to say nothing of the chance that the builder himself does not carry the grades from the stakes correctly, it is very difficult to prevent errors from creeping into the work, and it is to reduce these to a minimum as well as locate at once where any error has occurred, that this city has adopted the following system:

A complete building grade is made up of two parts, the application and the certificate. The application for a building level is made by the owner or his agent at the office of the City Engineer, giving the location of his lot, by the street boundaries as well as the lot and block number. This is a good check and has saved considerable trouble, as the public are more familiar with their street name than lot numbers. The application is then signed and a fee of five dollars collected before any work is undertaken.

The certificate for a building grade is made a complete record of the work done, starting with the office down to the marking of the grade stakes.

When a building grade has been given off a profile, it is good practice to mark the building grade number on the plan above the profile, together with the elevations to be set in the field. This will act as a caution point and immediately check any intended change in grade unless such change was absolutely necessary. The number refers you to the detail description in the record book. Some engineers keep a map marked up-to-date with each building grade set, but we have found the method of marking the profile much more convenient.

The elevations are now given to the instrument man to set in the field. Here it will be well to emphasize the importance of marking stakes. It is no exaggeration to say that 90 per cent. of the mistakes made in connection with building grades are made because the builder has not read the grade stakes correctly. When a grade is set by a stake not at the elevation of the actual grade the marking should read to give the exact idea of the elevation, such as 1'-0" above grade or 1'-6" below grade.

The grade given to the builder is the property grade or the elevation at which the finished boulevard, or walk, will be constructed adjoining his property. It has been found desirable to print an explanation of the term "property elevation" on the back of the certificate.

When questions come up in grade work, we want to know who set this particular grade, when it was set, and all other detail information connected with it. For this purpose the page and number of field work is given on the certificate, although this information is of no use to the builder.

The attached form is a combination of the application and certificate for building levels used in this city. They are bound in field book size of 100 alternate white and yellow

*Roadways Department, City Engineer's Office, Edmonton.

CITY OF EDMONTON FORM E. D. 3
ENGINEERING DEPARTMENT

APPLICATION FOR BUILDING LEVEL

Date May 16 / 1912 No. 675

I hereby make application for building level on North side of College Street between First St. and McDougall Ave. for lots 10 Block 4

Plan R. L. 6, and agree to pay $5.00 for the same. J. J. Smith
OWNER or AGENT

Mailing address 425 Sixth St.

CERTIFICATE FOR BUILDING LEVEL

Date set May 17 / 1912 F.B. No. 190 Page 50 Set by W. Milne

STATION	LOT	BLK.	PLAN	PROPERTY ELEV.	ELEVATION SET	STAKE MARKED	REMARKS
S.E. corner	10	4	R.L.6	240.20	241.20	1-0 above grade	nail in stake
S.W. corner	10	4	R.L.6	240.80	240.80	grade	nail in stake

Bench Mark No 76 At N.W. corner College and McDougall

Elevation 243.76

CITY ENGINEER

pages, the white pages being perforated so that they may be taken out and sent to the builder. By using carbon paper the yellow page is made a record.

On receiving this certificate the owner gets all the information connected with the building grade and is in a position to have this grade checked if at any future time he thinks his grade has been altered, while the Engineering Department have a complete book of record of all the building grades set in the city.

BRICK PAVEMENTS FOR COUNTRY ROADS.*

The use of brick for surfacing country roads is rapidly gaining favor with highway engineers and the general public.

In 1909, the New York State Highway Commission decided to use a more permanent form of construction than macadam for the main highways leading into the larger cities, as any of these macadam roads were in bad condition, due to heavy traffic and lack of systematic repairs.

Experience has shown that macadam roadway under heavy traffic, either wagon or automobile, is not economical, mainly on account of the high cost of maintenance. The New York State Highway Commission, after extensive investigation, decided to use brick construction on their main highways; and, as a result, in 1910, about 20 miles of brick highways were constructed in the vicinity of the city of Buffalo. These roads proved so satisfactory to the travelling public, as well as to the Maintenance Department (the cost of maintenance being so low) that the mileage of brick roads in the vicinity of Buffalo at the present time is about one hundred miles, and this mileage will be greatly increased during the year 1913 if the present plans of the Commission are carried out.

These brick highways connect the city of Buffalo and Fort Niagara (at the mouth of the Niagara River) by way of the city of Niagara Falls, and reach out, with Buffalo as a centre, to all points of the compass; and I feel confident that it will not be long until every important highway leading into Buffalo will be of brick construction. This is also true of many of the larger cities of New York State, and the villages are now adopting brick construction under State aid.

The process of manufacturing brick for paving purposes has become more scientific as the demand for brick has increased and the methods of construction improved.

Streets built twenty to twenty-five years ago were paved with wire-cut bricks of the same size as building brick. Later, re-pressed brick of the small size were used. When the constructing engineer asked for a projection on the brick which would separate each course so as to allow the filler to enter and bind the bricks, the manufacturers placed their trade mark, in the form of raised letters, on the side of the brick. Later, more pronounced lugs were demanded; these raised letters, or lugs, require a re-forming of the brick in stamping machines (erroneously called a re-pressing machine), and as a consequence the so-called re-pressed brick with lugs drove the old wire-cut out of the market. The size of the brick was also increased to that of the present block.

Highway engineers still demand a block with lugs, and in 1910 a wire-cut lug-block was placed on the market for their consideration.

The brick with its lugs being cut by a machine at one operation shows, consequently, all lugs of uniform size, while on a re-pressed block many of the lugs are malformed or a part remains in the mould.

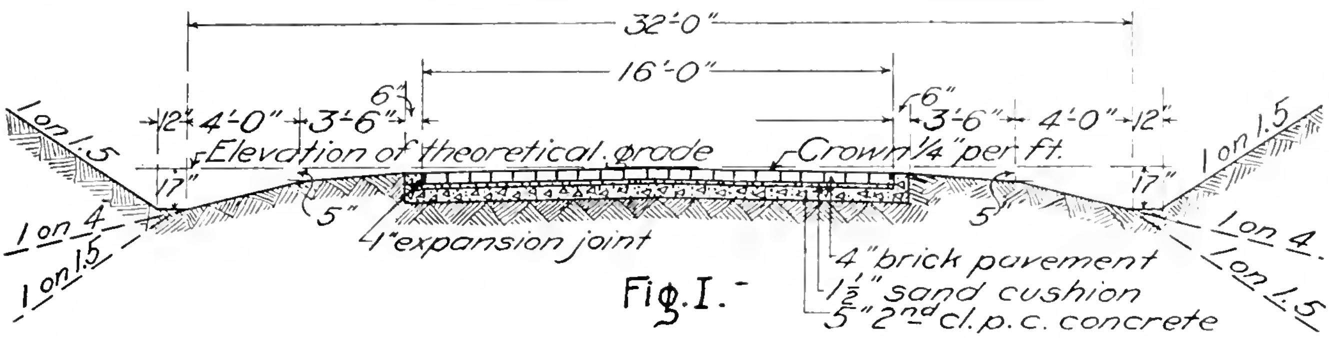


Fig. I.

Fig. 1 shows the New York State standard section for a brick country road, which calls for 16 ft. of brick surfacing, 1½ in. sand bed (this will be increased to 2 in. in 1913), and a foundation of 5 in. thick of concrete mixed 1 to 2½ to 5.

The brick surfacing is confined by a concrete edging 6 in. wide, flush with the pavement, and separated from the pavement by a well-defined expansion joint ⅞ to 1 in. wide.

For surfacing wider than 16 ft., these longitudinal expansion joints are increased proportionally to the width of pavement. No transverse expansion joints are used. In 1910, transverse expansion joints, placed fifty feet apart, were used with disastrous results, the blocks having become loose and crushing on each side of the joint. The shoulders or wings on each side of the edging are of earth, 7 ft 6 in. wide, making the width of the roadway 32 ft. between ditches; normal ditches are 1 ft. wide and 17 in. below the centre of the road or theoretical grade; back slopes of ditches, 1 on 1½; if necessary for proper drainage to

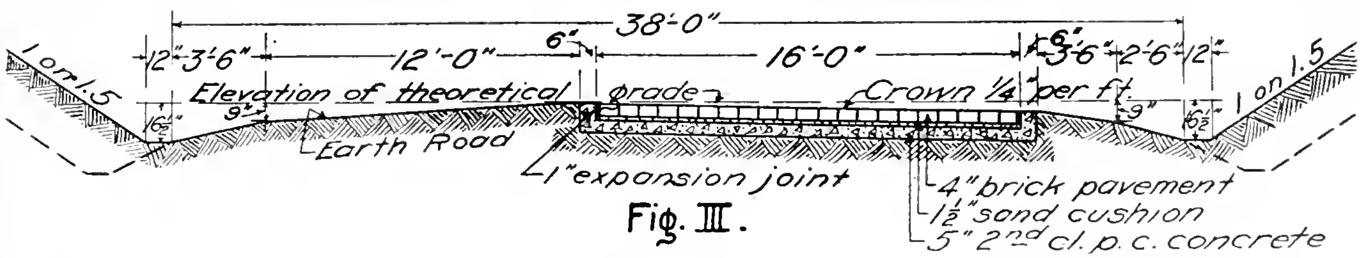

Fig. III.

* Presented at the Cleveland meeting of Section D of the American Association for the Advancement of Science by William C. Perkins, Resident Engineer, Department of Highways, State of New York, Niagara Falls, N.Y.

deepen the ditches or on embankment, the slopes are made 1 on 4 or 1 on 1½, but if the steeper slope is used, grade-rail is necessary. The crown of the brick section is ¼ in. per foot.

Fig. 3 shows a special section, combining a brick and earthen road, used on the highway between Niagara Falls and Buffalo. This is very similar to the section used on the roads around Cleveland. This section has 16 ft. of brick surfacing, with necessary edging and wing on one side of highway, and a 12 to 16 ft. earthen road on the other side.

Fig. 12.

This highway has just been constructed, having been opened for traffic on Christmas Day, and is 17 miles in length between the city lines. Fifteen miles of this highway is laid with wire-cut lug-blocks, the other two miles having been built in 1911 of re-pressed block. The traffic, especially automobile, will be very heavy. No traffic census has been taken, but on a Sunday afternoon (two weeks before the road was opened), at a time when it was necessary to make several bad detours, 256 automobiles passed a specific point in one hour.

The surface drainage is carefully examined, and concrete culverts used for the larger waterways and cast-iron pipe for the smaller.

The construction of a brick highway is in charge of a construction engineer, with a force of inspectors, and he is held responsible for the proper construction of the road and for all lines and grades. The method of construction is as follows:—

The road is first rough-graded, and when sufficient material has been excavated the sub-grade is rolled with a self-propelled road roller until it is thoroughly consolidated. Any weak spots that may develop are dug out and properly taken care of by either a sub-base course or a tile drain.

Fig. 15.

In some instances a combination of the two are used. The surface is then trued up by means of picks and shovels to conform to the cross-section.

The concrete used for base is made of 1 part of Portland cement, 2½ parts of clean, approved sand, and 5 parts of crushed stone or screen-washed gravel. The mixing is done by machines of the batch type.

Great care is used in having the concrete base smooth and of the same cross-section as the finished template, which rests on the edging forms, and is drawn as the work

Fig. 13.

Fig. 16.

In the preparation of plans for a brick highway on New York State work the designing engineer carefully examines the surveyed plan, making a new location of the centre if, in his judgment, it will improve the alignment; avoids all sharp turns, taking new rights-of-way if necessary. Easy grades are designed for the main highways, which often necessitates the cutting down of hills and the filling in of hollows.

progresses. Upon this concrete foundation a bed of clean, dry sand is laid, which is 1½ in. thick when pavement is complete. This sand bed is rolled with a hand-roller weighing about two hundred pounds, and then brought to the exact form and crown by means of a template of the proper shape resting on the edgings, or on scantlings embedded in the sand. The template is drawn forward and backward immediately in front of the brick-laying, so that the sand cushion is maintained constantly at the proper cross-sections.

On this sand bed the bricks are laid on edge at right angles to the edging, except at road intersections, where they are laid at such angles as directed by the engineer. All longitudinal joints are broken by a lap of one-half the length of the brick. The bricks are laid in close contact with each other by experienced bricklayers, with the lugs in the same direction.

After a stretch of pavement is laid it is inspected, and all soft, broken or misshapen bricks are removed. Any brick slightly spalled or kiln-marked is turned over, and, if the opposite face is acceptable, it is allowed to remain in the pavement, otherwise it is removed. Any unevenness or irregularities of the surface, after rolling, is removed by means of ramming.

The pavement is then thoroughly wet by sprinkling and the filler applied. This filler and its proper application is one of the essentials of a good brick pavement. The filler used is composed of one part Portland cement and one part sharp, clean sand, mixed in small quantities and care- object of a filler is to make the sur[illegible], [illegible] undue wear of the individual block, and to [illegible] the blocks together in a monolithic structure. The joint should become part of the pavement, and, as near as possible, of equal strength with the brick, all expansion and contraction to be counteracted by the use of well-constructed longitudinal expansion joints.

In constructing longitudinal expansion joints, two clapboards, or wedge-shaped boards, are used in each joint while the brick surface is being rolled and the cement filler applied. After the filler has been applied the boards are removed, the outside board being removed first in order to avoid loosening the blocks adjacent to the joint. The joint is then thoroughly cleaned to the full depth of the block and the pitch or asphaltum applied.

On all sharp curves we find it an advantage to use a wider expansion joint on the outside of the curve, as the tendency of the pavement is to move in that direction and away from the inside edging.

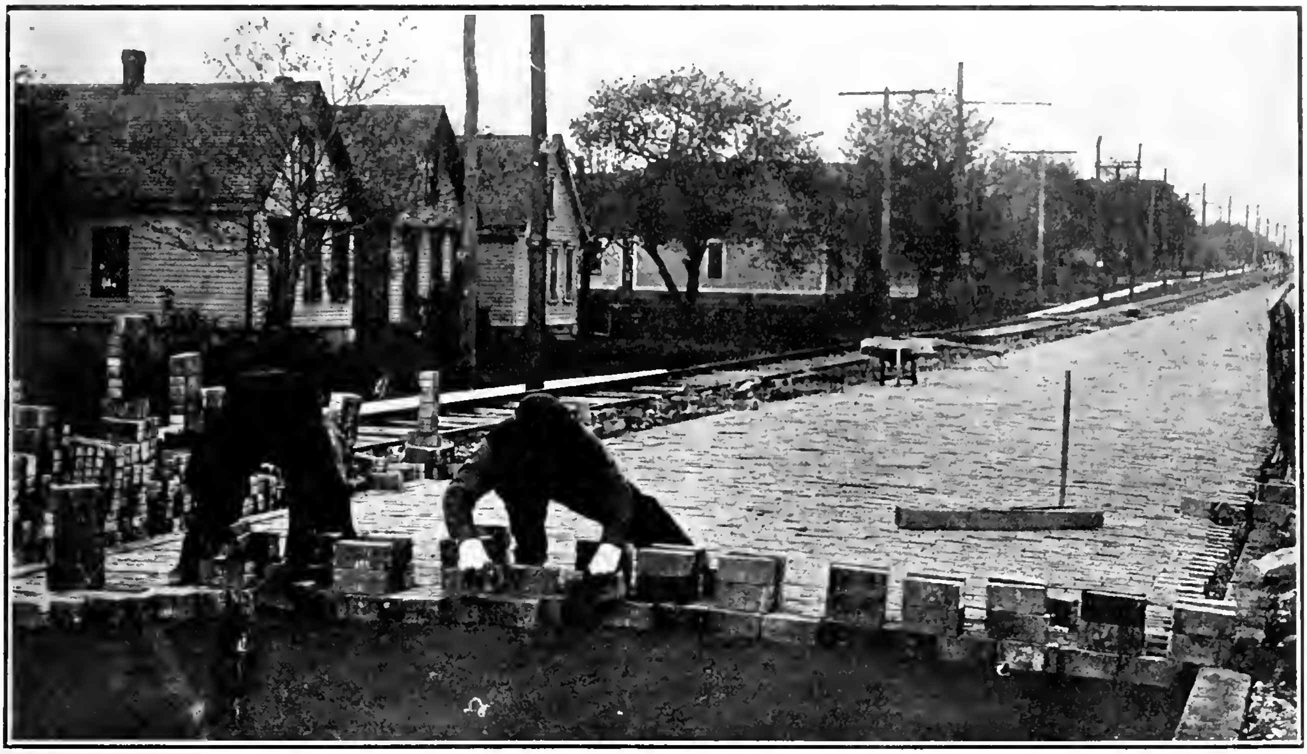

Fig. 14.

fully applied to the brick surface by means of scoop-shovels and swept at once into the joints by means of push-brooms or squeegees.

Before the cement has attained its initial set, the same portion of the work is gone over a second time, using the same mixture of grout, care being taken in each instance to thoroughly fill all joints flush with the top of the brick. Blocks with imperfect lugs, in order to secure flush joints, a third, fourth or fifth coat of grout is often necessary.

When sufficient time for hardening has elapsed, a coating of sand is spread over the whole surface and kept moist during the heated period of the day, in order to obtain as uniform a temperature as possible while the grout is setting. The roadway is then allowed to remain absolutely free from disturbance or traffic of any kind for a period of ten days. Some engineers advocate a weaker grout than a 1 to 1 mixture; others, a pitch filler, but my experience has been that better results can be obtained with a 1 to 1 cement filler, properly mixed and properly applied. The

All bricks are subject to tests for abrasion and impact, according to the standard methods prescribed by the National Paving Brick Manufacturers' Association. In 1910 and 1911, when the old form of rattler was used, a block which lost over 19 per cent. was rejected. In 1912, all tests were made on the new standard rattler, and all blocks which lost over 24 per cent. were rejected. Samples are taken at the roadside from every 200,000 block, or from any shipment which may be questionable.

As to the cost of brick paving on country roads, this varies according to local conditions. Highway contractors made use of various labor-saving devices to decrease the cost of construction. All unloading of stone and sand is done by machines. Many contractors are using traction engines for the hauling of material; some use small-gauge tracks with locomotives and cars. A modern concrete mixer is very necessary.

From data obtained from various roads a fair estimate of cost would be as follows, based on—

	Per hour.
Labor	$0.17½
Teams	0.50
Foreman	0.35

No office or incidental charges estimated.

Labor per square yard, brick paving in place, exclusive of concrete base:—

Unloading and piling brick	$0.035
Hauling brick one mile	0.040
Laying and rolling	0.070
Making sand cushion	0.020
Grouting	0.028
Expansion joints	0.007
Culling, replacing, etc.	0.005
Total labor, per square yard	$0.205

Fig. 17.

The manipulation of the concrete for the base varies from 40 to 60 cents per cubic yard, using batch machines and depending on gravel or stone concrete. The average bid price for brick pavement in western New York, including concrete base 5 in. thick, but excluding excavation, is $2.05 per square yard.

The brick highways constructed by the State of New York have given general satisfaction to the travelling public. Brick is the ideal pavement for heavy traffic; is smooth to the automobilist; originates no dust; is thoroughly sanitary; and, properly constructed, will be an inheritance appreciated by our children's children.

AMERICAN STATIONARY ENGINEERS.

The following is an abstract of the report made lately to the president of the National Association of Stationary Engineers by the National License Committee of the United States:—

The Indiana bill, endorsed by all of the State engineers' organizations, provided for a board of examiners of four members, the chief examiner acting as president, and the examining, licensing and classification of engineers and firemen. The examination fee is $3, and the fee for renewals, to be made annually, is $3, thereby making the department self-sustaining. The examintion board is authorized to reduce the fees when they exceed the expense of operating the department. This bill was approved.

The Oregon bill, which combines an engineer's license law and a boiler inspection law, is a model of its kind and framed to meet present-day requirements. It provides for a board of rules of four members, a chief inspector, ten deputy inspectors and a secretary; all inspectors to be selected by the merit system. The fee for internal boiler inspection is $5, and that for inspection while in operation, $2. It further provides for the examination, classification and licensing of engineers and firemen. The application fee is $1, and the license is issued for an indeterminate period, to be revoked for cause and renewed upon affidavit, when destroyed or lost. Penalties of fines and imprisonment are provided for employers and engineers violating the law. The annual renewal and license fee is eliminated. This, together with the requirement that the engineer keep a daily record of the condition and repair of all boilers carrying over 251 pounds pressure are two very important features that should commend the bill to the favorable consideration of both the steam user and the engineer. This bill also was approved.

Delaware reported that, having made four attempts to secure a State law, it may compromise on an enabling act, thus giving cities the right to enact local ordinances. Mr. Case, of New Jersey, has secured over 10,000 signatures to his petition for a license law, with good prospects of passage at the coming session of the legislature. Mr. Lee, of the New York license committee, will call a meeting later to determine the future policy of that committee. The Maryland committee reports progress on its proposed bill. South Carolina, which some years ago made a futile effort to secure a law, again desires to take up the matter, and will negotiate with the National License Committee to that end. The prospect of presenting a bill to the Pennsylvania legislature during the coming session is likely.

Mr. Coughlin reported that as the Kentucky legislature would not meet until 1914, license work in that State would be deferred until that time; that prospects in Indiana, with all engineer's organizations united on a bill, looked favorable for its passage at the coming session of the legislature.

Mr. Wirmel reported favorably on the Michigan, Illinois and Wisconsin state bills and on the Aberdeen (S.D.) ordinance; that the work in Ohio to broaden the scope of the boiler inspection law and to eliminate the engineers' license renewal fee would be submitted to the legislature.

CONTENTS OF THIS ISSUE.

OUR POTENTIAL WATER POWERS.

Nature has endowed Canada with vast resources in the water powers so thickly scattered throughout the country. These sources of power, by far the greater proportion of them still in potential form, will in the near future form one of the most valuable natural assets we have.

Cheap power is one of the fundamental requisites of a successful industrial community. With power available at a low cost, whether this be due to cheap coal, crude oil, gas or favorable hydraulic conditions, transportation conditions will usually adjust themselves.

Pennsylvania's supremacy in the iron and steel field is due to her vast supplies of coal and iron ore. The New England States, on the other hand, have developed as a result of the available water powers.

Ontario, unfortunately, has no local coal supply, but Nature has been kind in the ample provision she has made for the province in the many water powers throughout the province. These water powers, as the present sources of fuel become exhausted or their supply is restricted, will become more and more valuable. It is probable that the next decade will see a tremendous increase in hydro-electric developments in Central Canada. It is safe to predict that within twenty-five years there will be at least three million of electrical horse-power in daily use from the water powers of the Province of Ontario alone.

For many years to come it is probable that Ontario, and perhaps Quebec, will see more activity in the development of water powers than other parts of the Dominion, due to the distance necessary for transporting coal, and to the large number of cheap and available developments.

British Columbia is also most advantageously located with regard to possible hydro-electric power, and, no doubt, many of these, additional to those already used, will be exploited. With the vast coal fields of that province, however, there is not the same driving necessity for the immediate development of the water power resources.

If these water powers throughout the country are to be used in the best interests of the public, great care must be exercised in the allotment of franchises for their use. The several provincial governments and the Federal Government must be exceedingly cautious in granting rights of development to private corporations. Development should only be allowed with stringent regulations, and under short-terms leases.

PRECISE SURVEYING.

It is almost always a matter of satisfied and gratifying pride to the engineers, a subject of bewildering surprise to laymen, that tunnels starting miles apart, with intervening hills and mountains in between, can be made to meet as exactly as they do. Curving tunnels or straight makes no difference with the way they finally slap up against each other, squarely, face to face, and on the same level. When we consider the labor and money lost if they do not meet, the importance and responsibilities of the preliminary surveys that lead to the final alignment of tunnel then take on their true value.

In an article in this issue by Mr. Busfield, engineers not acquainted with the care exercised in this kind of work will find an able and interesting description of it in

its details. It is the last word in modern precise surveys. Everything, from the standardizing of tapes, making allowance for temperature changes and elevation of measurements, and finally taking only the mean of several readings, each read to one thousandth of a foot, was done. The instrument work for angles and levels was just as carefully carried out to the last practical and known point of human carefulness and instrument accuracy. After reading it, it is with the utmost confidence one looks ahead to Mount Royal Tunnel, and its several workings finally joining up perfectly true and exact as per plans.

GOOD ROADS.

A Good Roads Exhibition, the first of its kind in Canada, is being held in the Exhibition grounds, Toronto, the 24th inst. to March 1st. The Ontario Good Roads Association is also holding its annual meeting the 26th, 27th and 28th of this month in the same city. In connection with the present agitation for good roads, an agitation which extends from coast to coast of Canada, and which is gaining in strength and popularity with all classes, it is, perhaps, well to note the start of the movement. As far as we can learn, the Ontario Good Roads Association, organized in 1894, was the first association actively trying to interest the people in better roads. They instituted quite a campaign of education on it, and by 1900 a considerable number of townships had abolished statute labor, and road-graders and machinery was superceding former modes. To-day, provincial and federal aid for highways in considerable amounts is becoming part of the financial expenditure of Canadian legislatures. Moreover, there is at present before the Ontario legislature a bill regulating the width of tires, etc., on vehicles, which ought to greatly help in economically maintaining and improving the general state of roads. Heavy loads and narrow tires, while they have been for years most destructive to our roads, do not appear to have so impressed the people, and seem to have passed unnoticed in their destructiveness, as far as producing legislation has gone. It is a cheerful sign to see this bill before the House, and let us hope it will pass.

This paper would like also to congratulate the Ontario Good Roads Association on its untiring work for years towards better roads. Below is a copy of the programme for their general meeting.

PROGRAMME OF ONTARIO GOOD ROADS ASSOCIATION.

ELEVENTH ANNUAL MEETING.

Toronto, February 26th, 27th and 28th, 1913.

First Day.

Morning Session, 10 a.m.

1. President's Address—T. L. Kennedy.
2. Report of Executive—George S. Henry.
   Report of Committee on the Constitution.
3. Appointment of Committees.
   Inspection of Machinery Exhibit.

Afternoon Session, 2 p.m.

1. Address—H. C. Hocken, Mayor of Toronto.
2. Address—Colonel Henry Brock, President Toronto Board of Trade.
3. Address—Sir Edmund Walker, President Canadian Bank of Commerce.
4. Address—C. J. Foy, K.C., Perth.

Inspection of Machinery Exhibit.

Second Day.

Morning Session, 10 a.m.

1. "The Township Road System," D. W. White, Clerk of Middleton.
   Discussion.
2. "County Road Organization and Construction," W. A. McLean, Chief Engineer of Highways for Ontario.
   Discussion introduced by Dr. C. O. Fairbank, of Petrolea.
3. "Technical Course in Highway Engineering," A. T. Laing, Toronto University.
   Inspection of Machinery Exhibit.

Afternoon Session, 2 p.m.

1. Address—Hon. J. O. Reaume, Minister of Public Works for Ontario.
2. "Road Maintenance," Dr. L. I. Hewes, Engineer in charge of Maintenance Division, United States Office of Roads, Washington, D.C.
   Discussion introduced by E. A. James, County Engineer for York; John Roger, County Engineer for Perth, and James L. Tailor, County Road Superintendent for Wentworth.
3. "Stone and Gravel Roads," E. R. Blackwell, County Engineer for Leeds and Grenville.
   Discussion introduced by T. V. Anderson, County Road Superintendent for Lennox and Addington; R. H. Fair, County Road Superintendent for Frontenac; R. H. Jupp, County Road Superintendent for Simcoe.
   Inspection of Machinery Exhibit.

Third Day.

Morning Session, 10 a.m.

1. "Town and City Streets," G. G. Powell, City Engineer, Toronto.
   Discussion introduced by T. H. Jones, City Engineer, Brantford, and J. C. Gardiner, C.E., Niagara Falls.
2. "Steel Bridges," C. R. Young, C.E., Toronto.
   Discussion introduced by H. J. Bowman, C.E., Berlin.
3. "Concrete Bridges," Charles Talbot, County Engineer for Middlesex.
   Discussion introduced by R. W. Farley, County Engineer for Carleton.
   Inspection of Machinery Exhibit.

Afternoon Session, 2 p.m.

Reports of Committees.
Election of Officers.
Unfinished Business.
Meeting of Executive.

STORM WATER DISCHARGE.

By R. O. Wynne-Roberts* and T. Brockmann.†

(Continued from last week).

Impermeability of Surface.—It is palpable that rain falling on the surface of the earth will be absorbed in some proportion to the permeability of the soil, etc. Very little rain will run off sandy ground, but if the ground is hard clay, or close-grained rock, more will flow over the surface and be drained away. If the ground is already saturated, most of any rain falling upon it will flow off by gravitation to the lowest point. In the case of intense rainfall, the ground is unable to absorb the same proportion of water as it would if the rain fell in gentle showers, and consequently a larger percentage of it is drained away.

Following this method of reasoning, it will be observed that in the case of towns with well-paved streets and yards, and houses built closely together, the storm water discharge will naturally be expected to be greater than where the streets are constructed of more absorbent material or where the streets are not made at all. Where the buildings are further apart and the degree of permeability is greater, the discharge to be dealt with will be less.

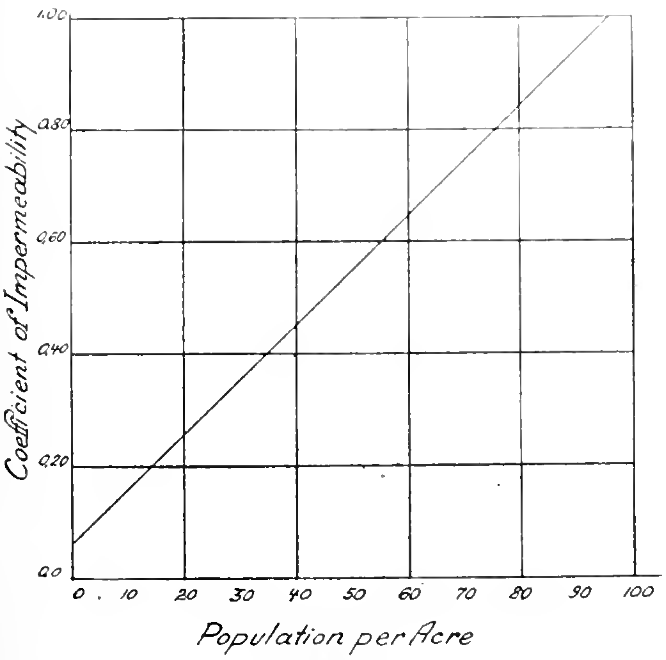

Fig. 1.

Mr. Wallington Butt, in a paper which he read in 1907 on the subject of "Calculation of Storm Water Discharge," rightly stated that the extent to which a town area has been built upon is, in some measure, also an indication of the impermeable area; in other words, the density of the population bears some relation to the area of impermeable surface in that district.

Mr. Wallington Butt, at the same time, submitted a diagram which he considered would assist to ascertain this factor, and this diagram is now reproduced for our present purposes. It is well, however, to point out that the limitation of this diagram is a population of 100 persons to an acre. Some towns have a much greater density of population than this, for instance, in Manhattan, New York, it approaches 1,200 persons per acre, but where it exceeds, say, 100, it can be assumed that the area in question is entirely built up on and the factor will be almost unity.

It is, of course, essential that the drainage area should be divided into smaller districts, the number of houses in each district be counted, and, allowing a certain number of inhabitants to each house, the population per acre is ascertained, and the diagram (Fig. 1) will give the coefficient of impermeability.

The following comparison of German and British standards will be useful:—

German classification of areas.	Equivalent British standard in population per acre.	Coefficient of impermeability
(a) Area densely built upon	75	0.80
(b) Area less densely built upon with larger yards	55	0.60
(c) Area having houses with larger gardens and yards	45	0.50
(d) Area openly built upon, detached villas, etc.	25–35	0.30–0.40
(e) Rural districts with gardens, meadows, etc.	15	0.20
(f) Parks, forests, etc.	5	0.10

Retardation.—In addition to the foregoing factors, which influence the manner in which storm water is discharged from any area, there is still another.

If the time required for the storm water to flow from the upper end of any sewerage system to any other given point is longer than the duration of the storm, then the water from the furthermost limits will reach the latter point when the water from the vicinity of that point has already been drained off, and thus the whole area, in such a case, will not be contributory simultaneously. In other words, the water from the remotest parts of the drainage area, owing to the distance it has to travel to the point in question, has been retarded from being discharged at the same time as the water from the parts near the lower point, hence the term "retardation." Mr. Baldwin Latham, one of the leading British engineers, stated that although rain fell in Manchester for 151 hours and 10 minutes, it took 1,008 hours for the water to flow off through the sewers, and this he attributed to an "extenuation of the flow."

To arrive at an appreciation of the influence of retardation, we may consider the subject in the following manner:

Let "L" denote the length of a sewer and "V" the mean velocity of the flow of water in the sewer, then if we consider a small quantity of storm water entering the upper end of the sewer, the time it will take to reach the given point or outlet will be $\frac{L}{V}$. If "D" denotes the duration of a storm, then the total time "T" from the commencement of the storm to the moment when the storm water will practically cease to flow through the sewer will be:—

$$T \text{ equals } D + \frac{L}{V}.$$

That is, the time for discharge, whether the water flows in an open water-course or in a close sewer, will be greater than the actual duration of the storm. But this fact does not warrant the sectional dimensions of the sewer being diminished, for such a reduction is possible only when the duration of the storm is less than the time required for the water to be discharged through the sewer, that is when "D" is smaller than $\frac{L}{V}$ or when "L" is greater than $V \times D$.

* Consulting Engineer, Regina.
† Civil Engineer, Regina.

With storms of great intensity and of small duration retardation will take place, even in short lengths of sewers, but when the storm continues for hours, retardation will have no influence, even if the sewers are of considerable length. It will depend upon the duration of the maximum precipitation assumed and on the velocity of flow in any particular sewer, whether or not retardation will take place.

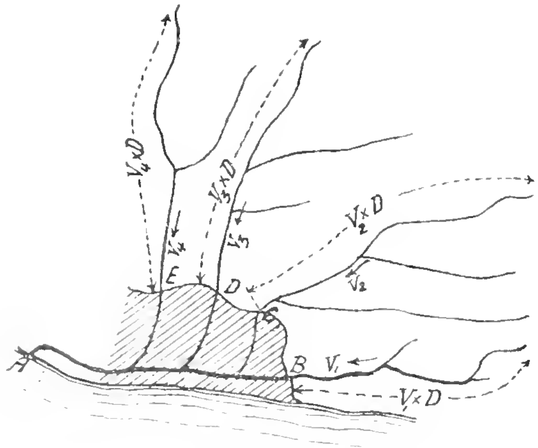

Fig. 2.

If the drainage area is within that part of a city which is built upon, then "V" will be determined solely by the inclination given to the sewer. The time required for the water from the roofs, yards and paved streets to drain into the sewers will be so short in comparison to the period which the storm water will take to reach the outlet, that is can be ignored. In the case of rural districts or openly built upon areas of a city, it will be necessary to allow a minute or so for the water to reach the sewers.

If an area such as is represented by Fig. 2 is considered, the value of V × D for the upper lengths of each sewer can be computed, and then the points B, C, D, E will indicate the limits of the area in which retardation will occur and must be taken into account.

In most cases the duration of a storm which will give rise to the maximum rate of flow will be not less than 20 minutes, or 1,200 seconds.

"V" is usually greater than 2.3 feet per second, therefore, in sewers shorter than 2,500 to 3,000 feet in length retardation may be considered as exceptional.

The question will now, doubtless, be asked, what will be the effect or influence of retardation on the discharge of storm water?

Such influence may be made clear in a simple manner if we consider a rectangular area E, F, G. H in Diagram F.

The line A-B represents the main sewer which drains the area bounded by the rectangle E, F, G, H. At the commencement of a storm of duration "D" the water from the vicinity of B will be the first to reach the outlet, and this is represented by the triangle H-C-B, which is shaded in Figs. 6 and 7. During the storm the adjoining area will be drained as indicated in Fig. 8. When the storm ceases, then the water from the vicinity of B will cease to flow, and this is indicated by the unshaded triangle H-N-G in Figs. 9 and 10. The length of the shaded part is equal to V × D. When the point C of the shaded part has reached the upper limit of the drainage district, then the extent of the figure representing the discharge will gradually diminish until the last portion of the storm water is drained away, as shown in Fig. 11.

Let "q" denote the quantity of storm water discharged per unity of drainage area.
"A" denote the extent of the drainage area.
"a" denote the contributory area,

then the ratio $\frac{q \times a}{q \times A} = \frac{a}{A}$ equals "R" the factor by which $q \times A$ has to be multiplied so as to obtain the actual quantity of storm water discharged. This factor is called the factor of retardation.

Example: Let "L" equal 12,000 feet; "V" equal 2.3 feet per second; "D" equal 1,200 seconds.

Then R equals $\frac{a}{A} = \frac{V \times D}{L} = \frac{1{,}200 \times 2.3}{12{,}000} = 0.23$ of the area.

By the foregoing discussion and diagrams it is manifest that, in addition to rainfall intensity, the configuration, extent, and shape of the drainage area, as well as the velocity of flow in the sewers, are the essential factors which may cause retardation.

Drainage Area, Configuration.—It is manifest that the permeability of a surface must be a question of degree, for even dense clay will absorb water if it is given time. If the drainage area is very flat and even rain water will naturally remain on the surface for a longer period, and will be gradually absorbed, evaporated or drained away. The time it takes to flow off the surface depends on the slope and general configuration. In a district which consists of hills and dales, the water will run off quickly. Configuration also constitutes an important element in the laying out of storm water sewers.

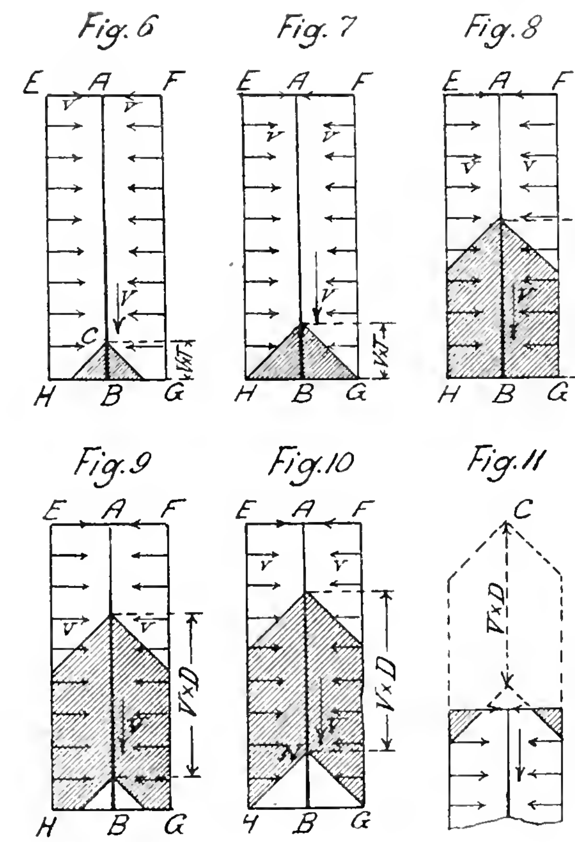

Diagram F.

Extent.—The extent of a drainage area, as far as retardation is concerned, is a matter of importance, so far as it is a function of its length. For it will be agreed that the time required for the water to concentrate at any given point will depend on the distance it has to travel and, according to statements already made, the intensity of a storm will vary inversely in proportion to the length of the sewers.

Shape.—The shape of a drainage area is another factor which has to be considered, for if the area is long and narrow, it will be observed that the period of concentration will be greater than if the area is compact.

Velocity of Flow in Sewers.—The factor of retardation is controlled by the velocity of flow in the sewers, inasmuch as the latter directly determines the time of concentration, that is $T = \frac{L}{V}$. If the sewers are laid with steep grades, a larger drainage area will be contributory, in a given time, than if the grades were made flatter. High velocities tend to eliminate retardation, whilst low velocities cause retardation to take place sooner.

Generally.—It is a matter of considerable importance that protection should be afforded the public against flooding, for apart from the disagreeableness of such an occurrence, it is also a menace to the health of a community. There is, however, a limit to which the engineer is justified in expending large sums of money in the construction of sewers of such dimensions as to be absolutely safe against flooding or gorging.

If the greatest rainfall intensity ever observed in any district is assumed as the basis for calculating the dimensions of sewers, it may be found that the sewers will be of such inordinate sizes that they will rarely be used to their full capacity and be so costly as to be financially impossible.

To adopt lower rainfall intensities will mean the facilitating of the execution of such works, but this may also incur some liability caused by occasional floods. The question, therefore, for the engineer to carefully consider is the disadvantages that may arise by the adoption of lower rainfall intensities as compared with the increased cost of larger sewers.

In Germany about 70 litres per second per hectare represents the lower limit, but this, according to observations made in Berlin, for instance, is exceeded about five times each year. To exceed 150 litres per second per hectare is recommended only in exceptional cases.

In districts such as Basel, where the annual rainfall (840 m.m.) is considerably greater than in Berlin (597 m.m.) a greater rainfall intensity is assumed, for instance, Burkli-Ziegler considered 125 to 200 litres per second per hectare as suitable for Switzerland.

Both Hawksley and Burkli-Ziegler's formulae were intended to include all circumstances which tended to diminish the discharge. Subsequent to their investigations, it was realized that the influence of the different conditions of impermeability of the surface deserved more attention and consequently other engineers introduced a separate co-efficient to cover that point. Following this slight development of the problem, however, German engineers have more fully developed the important features of the factor of retardation. Many capable American engineers have endeavored to construct a formula which will be generally applicable for computing the discharge of storm water, but they have met with very little success, because they tried to combine the heterogeneous factors affecting such discharge.

Mr. Lloyd Davies and Mr. Wallington Butt stated that the maximum discharge is attained when the duration of the storm equals the time of concentration. As the intensity of a storm varies inversely with its duration, in the case of sewers having great lengths the intensity will consequently be considerably reduced.

In many instances, however, it is not a storm of long duration and low intensity, but a storm of short duration and a great intensity, will cause the maximum rate of flow in sewers, even if only a fractional portion of the area is contributory. For example, in a district having an irregular shape, where the area near the outlet constitutes the major part, then during severe storms the water from that portion will concentrate quickly at the lowest point, whilst that from straggling and remote parts will require more time to reach the same place. It in such a case the intensity is derived from the time of concentration, then it will be too low.

It also often occurs that rainfalls of high intensity and short duration cannot be ignored, as they may happen when the sewers are already filled by the runoff of the preceding rainfall.

In an important case, it is highly desirable to ascertain which kind of rain will give rise to the maximum rate of flow.

A rainfall of high intensity will generally be assumed and the discharge ensuing is to be considered in its different stages. This can be effectively done only by constructing flow-areas as has been suggested by the late Prof. Frühling, of Dresden.

Such flow-areas can be drawn on squared paper, the horizontal lines—abscissae—will represent the time in minutes and the vertical lines—ordinates—will represent the volume of storm water in cubic feet.

The method suggested by the late Prof. Frühling will be explained in the next issue.

(To be continued).

INTERURBAN TROLLEY FREIGHT SERVICE AND RELATION TO HIGH COST OF LIVING.*

By Edward C. Spring,
Assistant to President, Lehigh Valley Transit Comany.

No agency in modern times has done more for the development of communities, the building up of municipalities and the revolutionizing of the social life among the masses of this country than the trolley systems of the United States. They have brought the farmer in close touch with the markets of the civilized world. They have brought the farmer's family in close touch with the educational advancement which this country offers, and to-day it seems to me that the interurban trolley lines of the country can do more to break down the middleman's profit and to place the product of the soil at the door of the consumer with greater dispatch and less variations in price than any other agency.

Recent legislative enactments in many of the States favorable to the handling of freight and express matter by the electric lines have caused the operators of such roads as are affected to establish a freight or express business. Hitherto the handling of trolley freight has received comparatively little attention in the East, considerably less in general than the attention given to it in the Middle Western States. But the roads of the Middle West have not fully demonstrated or satisfied themselves as to the best course to be pursued in taking care of this new branch of the service. The diversified conditions that exist among the various roads and the difficulty in harmonizing these various conditions present a situation which must be met. The growth of the freight and express business during the past four years has been wonderful. The frequency of service and the connecting of small towns between cities hitherto isolated from the outside world have been two of the greatest factors for the development of this branch of the service.

The number of advantages offered by the electric lines in the handling of commodities is fast becoming more apparent each day. The placing of the farmer in close touch

* Abstract of paper read before the City Club of Philadelphia January 18th, 1913.

with the markets of the world, through the medium of the electric lines, offers in itself one of the greatest inducements to the interurban lines running through a farming community. The establishing of freight stations and platforms in the various towns and cross-roads enables the handling of freight and express more carefully and with greater dispatch, and also makes a convenient place for the transfer of the merchandise. As the industrial and commercial needs press the interurban roads to keep pace with the demand for greater freight transportation, this need will be met in the same energetic and progressive manner as has characterized the past development of passenger transportation.

The great ease with which agricultural products can be brought into the large cities has enhanced farm values through the various territories served by the electric lines, together with the shipments of local produce into the cities, the counter-current of development of groceries and other store products to the various towns along the line takes place. That the various municipalities may be benefited from this new class of service, the farmer must be brought into close touch with the benefits of this service, as it concerns him.

Much has been told the farmer by the State Agricultural Institutes how to prepare the ground, till the soil and plant, to produce the best results, but very little has been told him how to find a market for his product after its development. It has been my interesting work in the Middle West, and is at present with the company that I represent, to bring the farmer's attention to the most important agency that has wrought a revolution in bringing the country into close proximity with the city and to familiarize him with the intermediate relations which exist between the transportation companies and the farmer. I am a firm believer that as the farmer goes, so goes the nation. To anyone who has studied the farming conditions in the Middle and Western States, this is most forcibly impressed. It is not a question to-day of the farmer taking his cue from Wall Street, but Wall Street being subservient to the will of the farmer.

The community in and about Philadelphia is splendidly served as far as the farmer is concerned by the up-to-date service of the transit companies, which have recently established a fast express service at freight rates between the various points and the city of Philadelphia. The company with which the writer is connected has established a brokerage department in connection with its express and freight service between Allentown and Philadelphia along the Lehigh Valley and through the North Penn region, whereby the farmer can secure a market for his commodity without going to the city or taking up his time. The company does not charge the farmer for this service. This is a great feature of the express service, and one which has never been handled by an Eastern trolley line before.

The time is past when the farmer does not put a valuation upon his own time and that of his team. To-day in the management of the farm, these two factors are entering in the maintenance account to a large extent. When the farmer can place his commodities upon the cars of the trolley lines, he can not only utilize his own time, but that of his team to greater advantage at home, rather than driving to market.

I have purposely tried to impress upon you the close relationship that exists between the farmers and the electric transportation companies in the great work and development of the farms and the products and the placing of the same within the reach of the masses at sane and rational prices. The farmer in the aggregate is not receiving for his product to-day any more than he did ten years ago, but the consumer in our large cities is paying from 50 to 100 per cent. more for the same goods, and it is certainly evident, even to the casual observer, that the middleman is the one who is reaping the major part of this advance, and to-day the one agency that is doing more to break down the middleman's profit is the freight and express service of the interurban lines.

The electric lines of the United States occupy no mean position in the commercial and mercantile interests of the country, and are in a position to play a very important part in the future development of the country. According to the last census, there are in the United States 1,279 operating companies, 40,088 miles of operated track, operating 89,601 cars. These companies have a total stock and bond issue, authorized, of $7,182,781,212, and outstanding, $4,682,106,217.

I firmly believe that the establishment of city markets at various sections of a large city, with tracks running directly to the same, so that the market garden products may be delivered directly to these markets, also various freight terminals to be established as near the centre of the metropolitan districts of the city as conditions may permit, would be one of great advantage to such city.

The city of Philadelphia, unfortunately, owing to the wide gauge of the city tracks, cannot allow direct communication without transfer from most of the outlying electric lines.

These matters should all have the attention and the endorsement of the engineers in laying out the future transportation plans for the city. The desire of the farmers to ship their goods over the electric lines in preference to steam roads is an evidence and proof of the benefits of this service.

The company, which the writer represents, is probably doing more to-day than any other electric railway company to develop this class of business, and transversing as it does the highly productive counties of Montgomery, Bucks and Lehigh, for a distance of fifty-eight miles to the north of Philadelphia, this company is in a position to serve the city to great advantage. So rapidly has the business of transporting farm products developed that this company has ordered several new cars to give increased service. The field of transporting farm products by the trolley lines, as far as the section in and around Philadelphia is concerned, has hardly been entered into as yet, and the large volume of business which will be developed by the trolley companies and the increased advantages which will revert to the city of Philadelphia cannot be estimated.

The recent advent of one of the largest old-line express companies on the Lehigh Valley Transit Company's line is but an added feature to the progressive and up-to-date methods that are being instituted for the benefit of the Philadelphia markets.

The key to the success of any interurban trolley service is its terminal facilities in the large cities. A system of trolley freight terminals must be established to better bring the producer and the consumer in close touch, eliminating all possible chances of the middleman. A fair adjustment of rates on the part of the city line with the interurban roads must be made, that the through rates for transportation between the farming districts and the city will be so attractive that the farmer will ship his product by means of the trolley rather than by any other. These are all factors which must be taken up in the city of Philadelphia in order to bring about the desired results. At the present time the city lines are receiving the same percentage of the through rate for a haul of five or six miles as the interurban lines are receiving for thirty or forty miles. It seems to me that these two factors, namely, terminal facilities and rates charged by the city lines, are most important and of vital interest to the city of Philadelphia in the development of the electric freight service.

A HIGHWAY DEPARTMENT ORGANIZATION FOR A LARGE CITY.*

By Wm. H. Connell.†

The most important and most neglected branch of the municipal governments to-day, is the division of highways. This is probably due to the fact that only within the past few years has the public taken an active interest in the condition of the streets. Wide avenues, good pavements and clean streets are not only appreciated but demanded by the public to-day, which accounts for the significant fact that every live municipality is struggling to develop a highway organization that will enable it to meet the demands of the public.

The time has arrived when municipalities must develop highway organizations commensurate with the present day requirements of this all-important branch of municipal government. It is needless to say that the development of up-to-date municipal highway organizations, like the good roads movement, is in its infancy, but the two go hand in hand and have come to stay, and if any governing body wishes to be popular with the public, it will be well for it to look to its highways. The highways represent the most conspicuous show case of the municipal government—thus the importance of paying particular attention to the goods placed there. It pays and pays well for business establishments to design attractive show cases, place their best goods in the window, and maintain a clean and attractive display; and so it would pay municipalities well to design attractive highways, lay good pavements, and maintain clean and attractive streets. It must be remembered, however, that this cannot be done by wishing. But unfortunately a half-hearted policy has been the one most in evidence in many municipalities to satisfy the popular demand for attractive highways and good pavements. The solution of the problem is an up-to-date municipal highway organization, made up of the right kind of personnel working as a unit.

No matter how large or how small the municipality may be, the underlying principles constituting the foundation of the highway organization are the same. If a lawyer or business man were going to build a house, he would employ an architect, tell him how much money he had to spend, give him an idea of the size of the house wanted, and leave the rest to him. He would also select an architect with experience in the design of the type of structure he wanted. The same procedure should be followed in organizing a municipal highway division, and it is a very simple one to follow. Select an engineer whose experience has been gained in highway organization work; tell him about how much money he will have to spend; give him an idea of the mileage and area of streets and the scope of the work coming under his jurisdiction; and he will build up a successful organization —provided he follows the same principles the architect must to design a substantial house, namely, select the materials best suited to support the structure. The highway organization, like the house, to be substantial must be composed of of men capable of upholding and controlling the respective divisions of the organization coming under their control. If this procedure is followed, the organization will be permanent and will stand, unless seriously interfered with, even in the absence of the engineer who built up the organization, member by member. When an organization is perfected, it is in the same category with the completed hou[illegible] requiring maintenance to hold its own. But if it is to be kept up-to-date, it will require changes and improvements commensurate with the demands of the time, and increased population—the house as well as the highway organization.

The outline of the underlying principles governing the procedure to be followed in forming a municipal highway organization makes it very evident that at most it is not a difficult task to start right, but right here municipalities only too often have failed. The lawyers and business men placed at the head of the public works departments have not followed the procedure they would in building a house or doing something else that would require a like amount of intelligence in the selection of the tools to work with. They have either attempted to build up the organization themselves, or have selected engineers whose principal qualifications have been that they were specialists in reinforced concrete, waterworks, sewer works, etc., or in short anything but highways. And what has been the consequence? These men spend three or four years or more groping in the dark, studying the rudiments of the requirements of a highway organization, and by the time they are just beginning to find themselves, and appreciate that highway engineering is a special branch of the engineering profession, the public has become impatient, and justly so.

This we all know has occurred only too often with well-intentioned administrations. Such control of the highway situation retards the advance of modern highway organization and engineering just as much as the old-time political administration of the highway bureau, and the reason is that the public expects something from the well-intentioned administration and doesn't get it, while in the latter instance they did not expect much and usually were not disappointed.

A proper start usually results in a good finish, but not without a hard fight, and even though the right engineer be selected to head a highway organization, his path is not strewn with roses. There is so much that is wrong and so little that is right in many of our municipal highway organizations, that the opportunity for constructive work is almost unlimited, aside from the efforts required even to keep abreast of the times with the construction work, and above water with the maintenance.

Assuming that a highway organization has reached the stage of development where its personnel is qualified to handle the work, the next and most important step toward efficiency and economy is to centralize the control of streets.

It may appear rather odd to some, but nevertheless it is a fact, that very few, if any, highway organizations control the streets coming under their jurisdiction. The control is usually divided up between the street railways, telephone, telegraph, electric light, gas, and other corporations. If when these companies tear up the streets they are permitted to make their own repairs, there results a confusion which takes away from the highway bureaus the direct control of street repairs. Such arrangements as are necessary should be made to place all repair work directly under the highway bureau. If the repair work is done by contract, the contract should be with the city. The highway bureau should have sole authority to repair or order repairs, of whatever nature, that are to be made. This would give the bureau a direct control over the contractors, and place the responsibility on the bureau for the condition of the streets and do away with the excuses we so often hear from city officials, that "The railway or telephone company is responsible for such and such repairs, and we are doing our best to push along the work." With this divided responsibility for the condition of the streets we can never expect to reach the highest point of efficiency in our highway organizations. The parkways

---

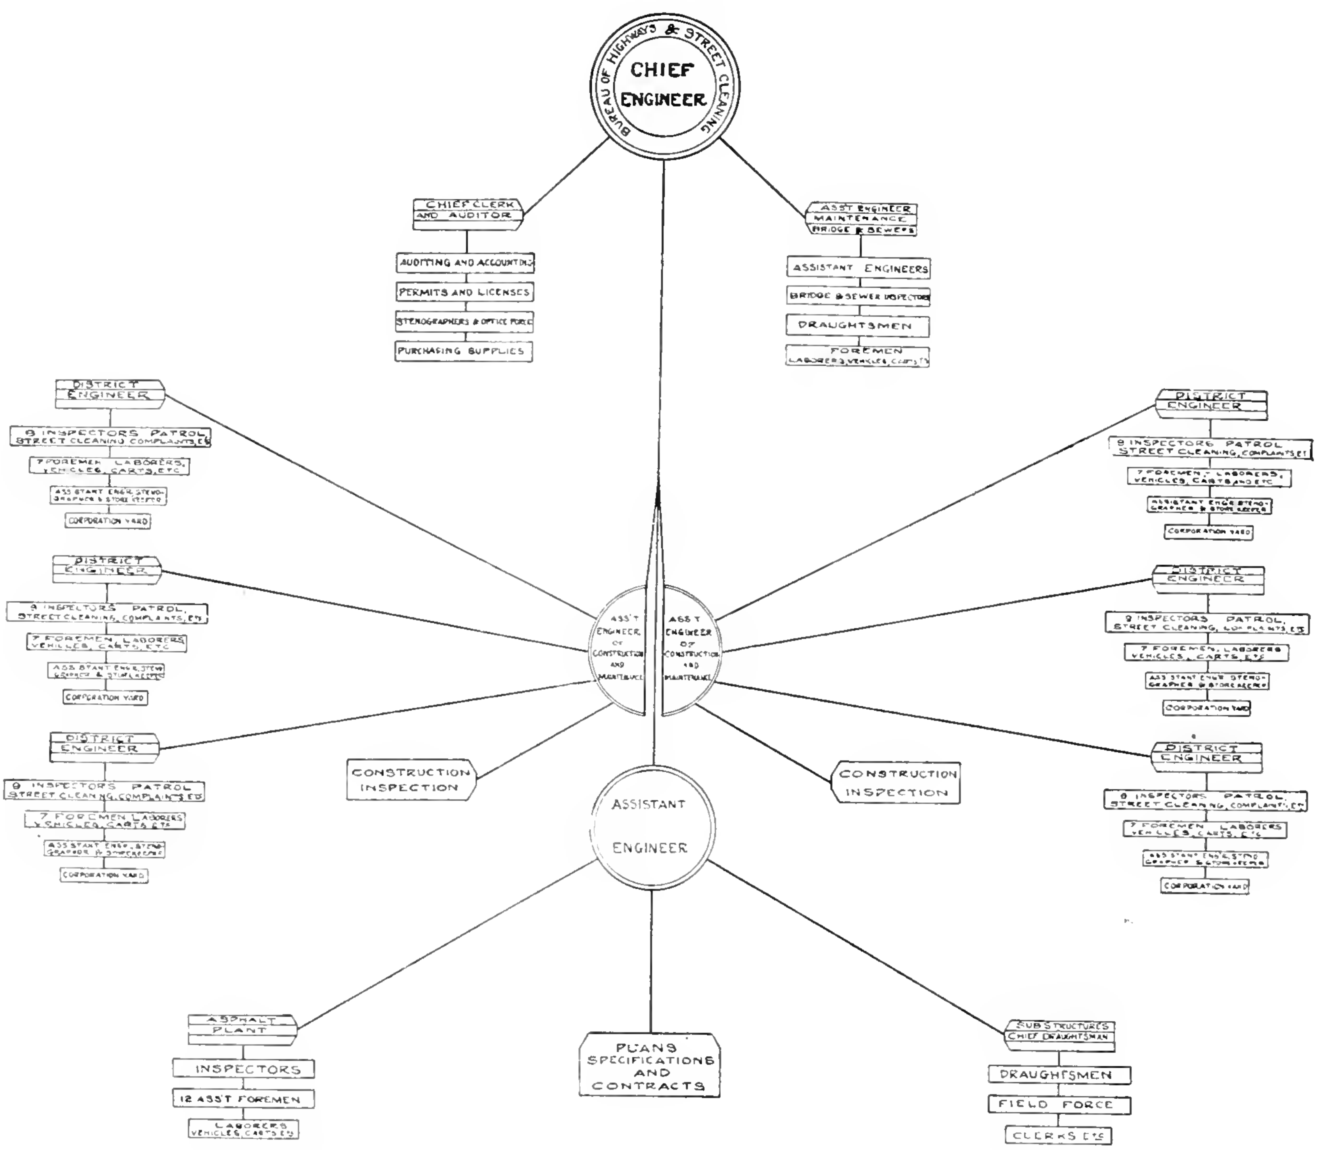
* From a paper read before ninth annual convention of Ameircan Road Builders' Association, held at Cincinnati December, 1912.

† Chief, Bureau of Highways and Street Cleaning, Philadelphia, Pa.

and main park driveways should also be under the control of the highway bureau as there should be but one system of highway construction and maintenance in the municipality.

The principle of centralization of control is the governing factor in a municipal highway organization, as it is also in any other organization of whatever nature. No business enterprise can compete with other business enterprises and be successful, unless the control of the organization is centralized and all the branches and subdivisions are co-operating and working as a unit for the success of the enterprise. This can be accomplished in a highway organization only of control, and such control cannot exist unless each individual in the organization is charged with his responsibility. If more attention were paid to the old saying, "Men will be led, but not driven," there would be less disorganization in municipal highway and other organizations.

Another very important step toward the control of street repairs is the establishing of municipal repair forces. The city should not be forced to depend upon contracts for work of this character and indeed, the only way to control completely wear and tear repairs as well as cuts is through municipal forces. Such repair forces naturally fall into four



ORGANIZATION CHART OF THE HIGHWAY DEPARTMENT FOR A LARGE CITY.

by first assuming such control of the streets that the responsibility for all conditions that may arise will be placed unqualifiedly with the highway bureau. Second, the subdivisions should be so organized that they will all be in close touch with the central office and working as a unit; there must be no overlapping of jurisdiction, and the policy emanating from the main office as to methods of carrying on the work, should permeate the whole organization. Each factor in the organization, from the common laborer up, should be schooled in a sense of his responsibility and know where it begins and ends. No man will do his best work unless he be instilled with a sense of his responsibility. The success of the organization at large depends upon co-operative efforts which can be brought about only through the centralization

divisions: Asphalt, stone block, wood block and brick, and macadam. In a few cities some success has been obtained with city gangs in repairing wood block and asphalt block streets but the big problem does not include either of these. Properly organized, a municipal asphalt plant is a step toward centralization of control over pavements, provided the area of asphalt pavements warrants a plant for repair work. No less important, however, are the repair gangs for the granite, brick and macadam pavements.

It is only within the last few years that the engineer has been finding out that city labor, properly handled, is far superior to that obtained through contracts. Ease in administration requires a municipal force for repair work as mobility cannot be obtained through any other than city

forces. In addition to this fact, it might be well to add that results obtained recently in various cities show a substantial saving by reason of the abandonment of contracts for repair work, and the substitution of city labor.

Too much emphasis cannot be placed upon the importance of centralizing the control over the pavements right in the highway bureau itself—and the larger the municipality, the more important it is that all street repairs be made by municipal forces. In any event, even though the organization is not equipped to handle the work, all contracts for repairs to cuts should be made directly with the city and not with the public service corporations. The most efficient and economic method of handling repairs, however, is by municipal forces.

After planning and working out a highway organization adequate for the requirements of the municipality, the first and most important step toward efficiency and economy in carrying out the work is the establishment of unit cost records, covering all classes of work carried on under the bureau. The basic principle of these records is simply to bring out by comparison the weak and strong points of the organization, which will act as a guide in planning and conducting the work in an efficient and economical manner. Comparisons of different subdivisions of one function of the organization may be made one with the other, or comparisons of like functions in different organizations, all of which tends to improve the methods of carrying on the work, impresses the men with their responsibility and at the same time arouses the sense of pride they should have in their work. Unit cost records are simply a modern system of records designed to raise the standard of efficiency and economy in conducting work. All maintenance work should be initiated through job orders issued from the main office, with the exception of emergency repairs, which work should be controlled through a job order issued by the superintendent or engineer in charge, a carbon copy of which should be transmitted to the main office. The foreman should be supplied with a force account and daily report sheets, through which labor hours, foreman's time, team time, and material used could be charged under their respective job order numbers and each day transmitted to the main office where the unit cost records would be compiled.

The accompanying chart illustrates a proposed organization of a bureau of highways which embraces construction and maintenance of highways, street cleaning, collection of garbage, maintenance of bridges and maintenance of sewers in a municipality, with a population of about 1,600,000 and 1,500 miles of streets and roads to care for, of which 1,000 miles are paved with first-class pavements, 300 miles with water bound and bituminous macadam and 200 miles of dirt road. It is assumed, of course, that all street repair work and bridge and sewer maintenance, as far as is practicable, will be done by municipal labor, and all original construction and repaving by contract.

The organization, it will be observed, is divided into five main divisions, which in turn are subdivided in accordance with the requirements of the functions of the respective divisions. A chief clerk is in charge of the clerical force, which embraces auditing and accounting, permits and license division, stenographers and clerks purchasing supplies, etc. The maintenance of bridges and sewers is under the direction of an assistant engineer, and is subdivided into two divisions, maintenance of bridges and maintenance of sewers. All minor repairs to bridges and sewers are made by municipal labor, more extensive repairs by contract. Sewer cleaning, of course, is done by municipal labor.

The supervision of all regulating and grading of streets, construction and maintenance of pavements and street cleaning is divided into two main divisions, each under the direction of an assistant engineer. Both of these divisions are subdivided into three districts, each under the direction of a district engineer. Each district has nine patrol inspectors, whose duty it is to report and measure all defects in pavements, plumbers' cuts, corporation cuts, and report encumbrances, answer complaints, etc., and supervise the street cleaning and collection of garbage, which have been assumed to be under contract in the organization under discussion. It is strongly recommended, however, that this work be performed by the municipality itself, as it is the only logical way to properly control it. It will also be observed that each district engineer has under his jurisdiction seven foremen, laborers, vehicles, carts, etc., assistant engineer, stenographer, storekeeper and corporation yard.

The number of patrol inspectors, assistant engineers, foremen, laborers, etc., may vary somewhat, depending upon the requirements of the respective districts, but the total number is approximately correct for the municipality at large.

Construction inspectors are assigned to each district as occasion requires by the assistant engineers of construction and maintenance. The other main division comprises the office force in charge of plans, specifications and contracts, the asphalt plant, and the division of subsurface structures, and is under the direction of an assistant engineer. The division of subsurface structures is a most important division, and the rules and regulations governing the placing of subsurface structures in the street, after a pavement has been laid, cannot be too strict. This is one of the most serious problems confronting the municipal engineer, and indications point to its not being under proper control in any municipality in this country. The only real solution of the problem would seem to be underground pipe galleries. The evil, however, can be minimized by exercising a more thorough control over the corporations by insisting on a strict compliance with rules and regulations designed to permit of as little disturbance as possible to pavements after being laid.

A testing laboratory has not been mentioned, as it is assumed that the municipality would have a laboratory equipped to handle the work of all the city departments.

The primary considerations in making up the accompanying chart were to illustrate a practical scheme for carry-on the work of an organization, such as referred to in this paper, by subdividing the responsibility for the work in such a manner that the chief engineer will not be swamped with detail, but at the same time will be in such close touch with all the work under his jurisdiction that he can intelligently direct and thoroughly control the operations of the bureau.

The organization under discussion has been used as an illustration in this paper, as it is one with which the writer is familiar, but is not presented as an ideal municipal highway organization—the object simply being to illustrate the essential features that must necessarily be considered in order to successfully control a municipal highway organization. The fundamental principles under discussion, however, would apply to any like organization; any deviations would simply be of minor detail.

A copy of the Queen's Engineering Works Magazine, published by W. H. Allen, Son & Company, of Bedford, England, has been received by The Canadian Engineer. This magazine is published primarily to keep their old pupils and apprentices in touch with this firm, and contains many articles of interest to them. We have been requested to call the attention of those interested through these columns.

BOOK REVIEWS:

BOOK REVIEWS.

Design and Construction of Steam Turbines.—By H. M. Martin, London. 372 pages; cloth; 7½ x 11 in. Longmans, Green & Co. Price, $6.00 net.

Reviewed by R. W. Angus, B.A.Sc.*

This addition to a fairly long list of books on this very important subject is written especially for engineers who have had sufficient training in thermodynamics and mathematics to understand moderately difficult theory. As it contains a good deal of descriptive matter, however, and a large number of dimensioned drawings, it should prove helpful to the less skilled reader. The author states that the theory contained in the book is based on articles contributed by him to "Engineering" (London), the illustrations and descriptive matter being also largely from the same periodical.

The first chapter is brief, and is designed to give an idea of the action of a turbine, and to explain in a very elementary way the different types of wheels in use, these types being illustrated by water turbines. The chapter is too short to be of much help to anyone not having a pretty general knowledge of the subject, and the author might, with advantage, have elaborated his explanation somewhat.

The next chapter deals with the flow of steam through blades and nozzles, and proceeds at once to compute the velocity of steam from nozzles and the work done during various forms of expansion. The Mollier diagram is introduced and used as far as possible in the calculations, the author assuming that the reader understands the theory of the diagram, although this is explained in a later chapter. This important diagram deserves a place in any such treatise, and the value of the book is enhanced by explaining the use of Mollier's diagram and giving a copy of it for use.

Chapter III. describes a number of experiments made on nozzles and blades, showing somewhat the effect of the shape of the nozzle. The book then deals in the following chapter with the impulse turbine, illustrating with the turbine of Dr. Laval. The velocity triangles are drawn, and a method explained of finding the "indicated work done" on the turbine shaft by which the author means the turbine output plus the mechanical friction. This is then used to determine the efficiency of the wheel itself, and the whole is illustrated by a numerical example.

A table is given of a series of tests on impulse wheels to determine the wheel efficiency. The chapter concludes with a discussion on shock and proper velocities in the bucket.

In Chapter V. there is a discussion of the term efficiency ratio, or the ratio of the theoretical to the actual steam consumption, and the reasons for adopting multi-stage expansion, together with the resulting losses. The method of proportioning the turbine is merely suggested. In the following chapter a very interesting set of curves is given, which enable the designer to infer the results which he will obtain on a given turbine from the results of tests made on a similar turbine under different conditions, these curves enabling one to reduce any set of observations to corresponding results under a different set of conditions.

The actual design of the impulse turbine is dealt with by the author in two steps, the first dealing with the general proportioning of the parts and the determination of the probable steam consumption, etc., while the second step deals with the dimensions of the blading. The method of procedure is altogether too complicated to be discussed in this review. In general it may be stated that the limitations of the work have forced the author to assume formulas without proof, to which, however, fair exception could scarcely be taken. A chapter has been devoted to velocity compounded impulse wheels.

A number of chapters have next been devoted to reaction turbines and their design, which have been treated with a fair degree of completeness, and some difficult problems in this part of the subject are dealt with. Numerical examples have been given in certain places, and there are many useful tables and practical coefficients.

Following a chapter on the radial flow turbine, the author has given a considerable amount of theory and explanation of the thermodynamic principles involved in the turbine design, dealing also with the Mollier diagram, which has been used in earlier parts of the work.

Having treated the design from the thermodynamic standpoint, the author devotes a number of chapters to the mechanical details, there being a chapter on each of the following: Balancing, Dummy and Gland Packings, High-speed Bearings, the Strength of Rotating Discs, Geared Turbines, and the Condenser, this part occupying a fair proportion of the whole work. One could not expect the most complete treatment of these matters in a book of the size under discussion, and yet the treatment is fairly complete. For example, in the part dealing with dummy and gland packings various designs have been sketched and the method of calculating the probable leakage discussed in detail. Some dimensioned drawings have also been given.

The latter third of the book is almost entirely descriptive, and gives details of all the principal turbines, such as the A. E. G., Curtis, Rateau, Zoelly, Parsons, etc., most of the descriptions being accompanied by detail drawings

* Professor of Mechanical Engineering, University of Toronto.

with many dimensions, thus making them of considerable value as guides to the designer.

The book, on the whole, is well gotten up, its make-up being much better than is found in general in engineering books, but it is rather unfortunate that it has not been made into a more portable form. The large pages, heavy paper, well-spaced lines and good margins are attractive, but tend to make a book rather heavy and unwieldy, as in the present case.

The engineer who is well versed in his theory should find the book a real addition to the literature on this subject; other readers will have to confine their attention largely to the descriptive parts.

American Civil Engineers' Pocket Book. Published by John Wiley and Sons, New York. Canadian agents, Renouf Publishing Company, Montreal. Second edition, enlarged. Morocco, 1,483 pages, 500 tables, 1,200 cuts, 16 mo. Price, $5 net.

This pocket book, which has now appeared in the second edition, and of which Mr. Mansfield Merriman is editor-in-chief, has been very well received by the engineering profession.

Two new sections have been added to this second edition: Section 14, setting forth those fundamental principles and facts of Steam and Electrical Engineering, which are of especial importance to civil engineers, and Section 15, giving the most recent practice in the construction and maintenance of highways and streets. Eight new pages have been added to the chapter on Earthwork Computations. Section 3, which formerly treated of roads and railroads, has been revised, and is now entirely devoted to Steam and Electric Railroads, seven new pages being added. Many other changes throughout the book are noted, to correct ambiguities, supply deficiencies, and bring the subjects up-to-date.

The index has been revised and entirely reset, and the preface states that all known errors, typographic and otherwise, have been corrected, and that alterations and corrections have been on more than one-fourth of the pages of the first edition. Necessarily, in the first edition, this book, which is the compilation of so many different authors, contained a number of errors. A list of these errors has been prepared, and a copy will be sent to any purchaser of the first edition who forwards his address for that purpose.

This issue contains 23 articles, 43 tables and 18 cuts more than the former edition. The volume in its enlarged form will certainly be most useful to the members of the profession and everyone who is at all interested in engineering should possess a copy.

A Manual of Cement Testing. By Richards and North. Published by D. Van Nostrand Company, New York. Cloth, 137 pages. Price, $1.50 net.

Reviewed by P. Gillespie, B.A.Sc.*

This little volume is intended for the guidance of analysts and inspecting engineers, and gives in small compass, the methods in general use of making physical and chemical examinations of Portland and other cements. No attempt to elaborate any special theory or to leave the beaten path has been made. An examination of the text gives one the impression that precision of statement and literary accuracy have not received the attention that they should receive in the preparation of a text book. Clay for example, is defined as a "more or less plastic substance composed chiefly of aluminium silicate formed by the decomposition of minerals"; limestone is said to be "a substance formed where clay has been deposited with a calcareous matter." Elsewhere we are told that "samples should be taken more often," and that "tests often do not check closer than 10 per cent." On page 41, one observes that "compression tests are not used as standard tests for the reception of a cement," and that "the form and size of the specimen most generally used are two inch cubes. . . ."

Within the covers of the little book, notwithstanding, is found much information on the appliances for and methods of cement examination. The appendix consists of a reprint of the standard specifications for Portland cement of the American Society for Testing Materials, 1909, and the methods of analysis of raw materials, cements, etc., suggested by the Society for Chemical Industry. The book, as a handy and compact guide to routine work, possesses some value.

*Associate Professor of Applied Mechanics, University of Toronto.

Manufacture of Iron and Steel. By H. R. Pearson, M. I. Mech. E., Kiangnan Arsenal, Shanghai, China. Published by E. & F. N. Spon, Limited, 57 Haymarket, London. Cloth; size, 6 x 9 in.; 104 pages; 21 illustrations. Price, $1.15.

This book seems to have for its object the giving of an outline of the principal operations connected with the manufacture of iron and steel. It is put in an interesting way for all, and is designated a hand-book for engineering students, merchants and users of iron and steel. This about correctly infers what one would expect to find in the book. It is not highly technical, but where technical expressions are used and necessary, they are often not explained till several pages further on in this book. For an untechnical man to properly read and understand the book it ought to be read through twice, the first time to obtain a general idea of contents, and then more carefully. It contains thirteen comparatively short chapters, with numerous little cuts and tables, as follows:—

This book ought to be of interest to all who, in a general way, are interested in the manufacture of iron and steel, and of value to students or others starting work in steel plants and desiring to quickly understand the practical work going on around them.

The New Building Estimator. By William Arthur. Published by the David Williams Company, 231-241 West 39th Street, New York. Flexible leather. Size, 4½ x 7 inches, 712 pages. Price, $3 net.

This book on estimating, first published in 1904, has now reached the eleventh edition. It is, without question, the best book of its kind to be obtained to-day covering the necessary data for the calculation of the cost of building construction. The subject matter is taken up both in detail and approximately. The value of this double arrangement lies in its giving the appraiser or estimator—who has to give quick and approximate figures—the information desired, while the detail section provides figures covering quan-

tity of material and the labor required, in carefully checked and prepared form.

In this present edition, all prices have been corrected, and about 250 pages of new matter covering reinforced concrete, measurement of building work, comparative costs, sprinkler systems, valuations, railroad figures, grain elevators, square foot costs, cost of wood trusses, equipment of buildings, apartment houses, etc. The style of binding has been much improved by the use of gilt-edged flexible leather in place of the previous stained edges and cloth covers.

In every way this book on estimating can be recommended both to the engineer and the architect. Certainly no engineer should be without a copy for ready reference.

Book of Standards. Published by the National Tube Company, Pittsburg, Pa.; 1913 edition. Pages. 559. Size, 4 x 6½ ins. Price, $2.

The 1913 edition of the Book of Standards has just been received from the press. The present edition, which is the first since the 1902 edition, is much larger and more complete than the older one. It is printed on Canterbury Bible paper, the book, including the binding being not quite five-eighths of an inch thick and will fit the pocket readily.

The information incorporated has made it strictly a pipe handbook, and as such, it is believed, will find an immense use with the trade. The index of the book will be found to be very complete, all headings being thoroughly cross indexed. There are approximately 4,000 references found in the index. Several pages are devoted to a descriptive article covering the main process of manufacturing both welded and seamless tubes, also giving information in regard to the threading, durability and physical properties, etc., of both "National" pipe and Shelby seamless steel tubes. There are a number of pages which give weights, dimensions, threads per inch, test pressure, sections of joints, specifications, ets., of the various kinds of pipe and tubing made.

An article on Protective Coating, Matheson Joint Pipe, and Converse Joint Pipe contains desirable information on these subjects. Tubular electric line poles receive considerable attention, the information given will help an engineer in understanding more about tubular poles which are being used by many of the larger cities as a medium for better service, better appearance, etc. Various types of joints are described and illustrated. Full tabular information is given for poles from 22 to 40 feet, showing lengths of sections, size of butt, weight, thickness, greatest load pole will carry, etc. Several pages describe, illustrate and contain tables in regard to lapweld and seamless tubes, upset and expanded, wrought pipe bends, butted and strapped joints, bump joints, valves and fittings, including various kinds of nipples and flanges, band railings and ladders, working barrels, cylinders, Shelby seamless specialties, Shelby seamless cold drawn trolley poles, tables of various physical properties of Shelby seamless steel tubes, physical properties of carbonic acid gas, Briggs' Standard, holding power of boiler tubes, thermal expansion of iron and steel tubes.

Considerable prominence is given to articles on strength of tubes and cylinders under internal fluid pressure and collapsing pressures. Both of these papers are very complete and have been extracted from papers by Prof. R. T. Stewart, Dean of Mech. Engr. Dept., University of Pittsburg, and read by him before the A.S.M.E. Several of the formulae are compared and results of actual tests are given. Tables are given which show the probable collapsing and bursting strengths of standard tubes. These articles and tables will prove of immense benefit to the mechanical engineer, especially in the connection with boiler engineering problems. An article covering pipe used as columns is given, tables are supplied showing the use of standard, extra strong, and double extra strong pipe based on the New York Building Code as well as the Chicago Building Ordinances.

Considerable attention is given to the mechanical properties of solid and tubular beams, of usual and unusual shapes. As tubing is finding considerable usage in the mechanical field, notably in automobile construction, this data is particularly useful. This article is accompanied by tables giving the mechanical properties of solid and tubular beams of uniform cross section, various conditions of loading are illustrated and formulas are shown to secure their physical properties values. Unusual shapes are illustrated and formulae given to secure their properties as beams or columns.

An article on safety factors and safe working stresses is given which shows through what ranges values should be used for safe operation. Chapters are supplied giving information in regard to water, gas, steam and air. It has not been the intention to go very deeply into these various subjects, only in so far as they concern tubular products. Perhaps the scope of these articles is best shown by giving a list of some of the headings, information in regard to which is given in detail:

Water.—Properties, Boiler Incrustation and Corrosion, Flow in Pipes, Measurement of Flowing Water, Water Power, Tables.

Gas.—Physical Properties of Cases, Flow of Gas in Pipes at both High and Low Pressure.

Steam.—Properties, Superheated Steam, Flow of Steam, Loss of Heat from Steam Pipes.

Air.—Properties, Expansion, Compression, Flow of Air.

A large collection of tables in conjunction with explanatory articles is given; an idea of the extent of which can be secured from the following list:—Fifth roots and fifth power; decimals of a foot for each 1-64 of an inch; decimals of an inch for each 1-64; wire and sheet metal gauges in approximate decimals of an inch.

Proportions of screw threads, nuts and bolt heads, illustrated explanatory article accompanied by tables showing dimensions of screw threads, nuts and bolts. Several pages are devoted to area and weight factors for tubes and pipes by means of which it is readily possible to figure tne area and weight of various kinds of tubing. A special table is shown by means of which it is possible to find directly the weights of nearly all sizes and thickness of steel tubing up to 36 inches in diameter. By means of factors weights of various other metallic tubing can be found. A table showing properties of tubes and round bars is given with an explanatory article. This table gives various physical properties, including circumference, area, weight, surface in square feet, volume, moment of inertia, radius of gyration, etc., for tubes and round bars up to and including 36 inches. This data is given in increments of .01 inches up to 16 inches and increases from there by ⅛ inch increments to 36 inches.

The metric system is included with conversion methods for most of the more commonly used measures, including temperatures. A glossary of terms used in the pipe and fittings trade will be found in the back of the book, and in many instances the meanings of many of the more or less well-known words used in this trade are defined.

Practical Mathematics for the Engineer and Electrician.—By Elmer E. Burns and J. G. Branch, B.S., M.E., Member of the Board of Engineers for the city of St. Louis, Member of the American Society of Mechanical Engineers. 8 x 5½ in.; cloth; 143 pages. Price, $1.00. The J. G. Branch Publishing Co., Chicago.

The authors assume that the reader knows little of mathematics, and the book is chiefly intended for the operating engineer and electrician. Those engineers and electricians who have never had the advantage of a college education will not find it written above their heads. It is also of value to those who have had a mathematical training on account of the practical way in which the subjects are treated. Apparently, it has been the aim of the authors to write it in simple, elementary and clear language, and to confine it to subjects of especial value to all practical workmen. The subjects treated cover a wide scope, but no subject treated requires knowledge of any preceding subject or any previous knowledge of mathematics. A person fully understanding all the subjects treated will pretty well have all the mathematics that is required to make him a first-class operating engineer or electrical worker. Practical questions with answers worked out are given. There is no list of contents to the book, merely an alphabetical index of the subjects treated.

PUBLICATIONS RECEIVED.

Bureau of Mines.—Twenty-first annual report for the year 1912. Printed by the Legislative Assembly of Ontario. 300 pages; five sheet maps accompanying the report; 17 sketch maps and plans; 130 illustrations. Contents: Statistical Review; Mining Accidents; Gold Fields of Lake-of-the-Woods, Manitou and Dryden; Porcupine Gold Area; Water Powers in the Porcupine Gold Area; Swastika Gold Area; Cripple Creek Gold Area; West Shining Tree Gold Area; Notes on McArthur Township; Geology of the Detroit River.

Barge Canal Bulletin.—January, 1913. Published by the Department of the State Engineer of State of New York. 40 pages. Contents: Progress of Contract Work; Progress of Plans being Prepared; Plans before Canal Board; Contracts Advertised; Bids Opened; Award of Contracts; Annual Report of State Engineer and Surveyor, first part.

Report of the Department of Trade and Commerce. For the year ending March 31st, 1912. Contains miscellaneous information on bounties, lumber, and staple products, revenue and expenditure of Department of Trade and Commerce, statistical record of the progress of Canada, tonnage table, etc. Department of Trade and Commerce, Ottawa.

Application for the Revision of the Toronto Building By-law.—A memorial presented to the Mayor, Board of Control, and City Architect of Toronto by a general committee of citizens representing various technical and business organizations of the city of Toronto. C. R. Young, 318 Continental Life Building, Toronto.

Bulletin of the Imperial Institute.—A Quarterly Record of Progress in Tropical Agriculture and Industries and the Commercial Utilization of the Natural Resources of the Colonies and India. Edited by the Director and prepared by the Scientific and Technical Staff of the Imperial Institute and by other contributors.

Engineering Problems Connected with Biological Sewage Disposal.—By T. Aird Murray. Part of a Symposium on Biological Sewage Disposal, Canadian Public Health Association, Annual Meeting, November 21st to 23rd, 1911. The Canadian Engineer, 62 Church Street, Toronto.

Roofs and Their Coverings. By Clough Williams-Ellis. Being the paper on Welsh slates. Re-printed by permission from "The Architect and Contract Reporter." Published by Spottiswoode and Co., Ltd., London, Colchester and Eton. Price, six cents.

Public Service Commission. Report of the Commissioners, Vol. 1, 1912. Comprises report on government dredging, report on the Department of Public Printing of Stationery, and special report on Temiskaming dam contract, Sorel shipyard and dismissal of R. E. Cook.

Weekly Report, Department of Trade and Commerce, Ottawa.—Bulletin No. 473, February 17th, 1913. Pages 183 to 205. Contents: Australia, Trinidad, Great Britain, Panama Canal, Canadian Produce Prices in England, British Agricultural Produce Imports, Grain Statistics, Trade Inquiries.

Methods of To-day on (1) Swimming Bath Water Purification, (2) "Overground" Conveniences, (3) "Vacuum" Exhausters, (4) Dry Closets, (5) Fly-proof Privies.—By James S. Dunn, Sanitary Department, Town Hall, Kimberley, S.A.

Water Supply of San Francisco. Report by H. M. Chittenden. A well illustrated cloth-bound book, 11½ x 9 in.; 44 pages. Secretary, Department of the Interior, Washington, D.C. This is a very beautifully gotten up report.

Hydro-Electric Power Commission. Third and Fourth Annual Report of the Province of Ontario for the year ended October 31st, 1911. The Hydro-Electric Power Commission of Ontario, Continental Life Building, Toronto.

Coal Mine Accidents in the United States. Monthly statement, January to August, 1912, and Statistics for 1910-11. Compiled by Fredk. W. Horton. Bureau of Mines, Department of the Interior, Washington, D.C.

Influence of Icebergs on Land on the Temperature of the Sea. By H. T. Barnes, B.Sc. Being supplement of the 45th Annual Report of the Department of Marine and Fisheries for the year 1911-12, Ottawa.

Cement Process of Excluding Water from Wells, as practised in California.—By Ralph Arnold and V. R. Garfias. Bureau of Mines, Department of the Interior, Technical Paper No. 32, Washington, D.C.

Engineering Experiment Station.—Bulletin No. 29, the Iowa State College of Agriculture and Mechanic Arts, on Cost of Producing Power in Iowa with Iowa Coals. By H. W. Wagner, Ames, Iowa.

Practical Kinks, Recipes and Tables. Collected by Joseph G. Branch. Published by the Joseph G. Branch Publishing Co., 608 Dearborn St., Chicago, Ill. Cloth; 5½ x 7½ in.; 143 pages. Price, $1.

Railway Statistics of the Dominion of Canada for the year ending June 30th, 1912. (From sworn returns furnished by the several railroad companies.) Department of Railways and Canals, Ottawa.

Questions With Answers on Pumps and Pumping Machinery. By W. H. Wakeman. Published by the Joseph G. Branch Publishing Co., Chicago, Ill. Cloth; 5½ x 7½ in.; 190 pages. Price, $1.50.

Alternating Currents Simplified. By E. E. Burns Published by The Joseph G. Branch Publishing Co., 608 South Dearborn St., Chicago, Ill. Cloth; 5½ x 7 in.; 199 pages. Price, $1.50.

Treatise on Scientific Methods of Concrete Construction, Using Lock Steel Form.—By the Hotchkiss Lock Metal Form Company. Sixteen pages, with an attached sheet of about twenty cuts.

The Resources of Tennessee.—Magazine devoted to the description, conservation and development of the resources of Tennessee. Published by the State Geological Survey, Nashville, Tenn.

The Production of Copper, Gold, Lead, Nickel, Silver, Zinc and other Metals in Canada During the Year 1911. By C. T. Cartwright, B.Sc. Mines Branch, Department of Mines, Ottawa.

Obligations of the United States as to Panama Canal Toll.—By Hon. E. Root, of New York, in the Senate of the United States. Address The Congressional Record, Washington, D.C.

Proceedings of Ontario Association of Architects.—Being transactions of the Special General Meeting and twenty-third Annual Convention. 96 King Street West, Toronto.

Facts About Treating Railroad Ties.—By W. F. Goltra. Twenty-four pages on the Essentials for Effective Work in Timber Treating. W. F. Goltra Tie Company, Cleveland, Ohio.

Report of the Minister of Public Works for the Province of Manitoba, for the year ending December 31st, 1911. Department of Public Works, Parliament Buildings, Winnipeg, Man.

Index to the Weekly Report.—Published by the Department of Trade and Commerce, Ottawa, for the year ending December 31st, 1912. Weekly reports number 414 to 466.

Report of the Minister of Public Works for the Province of Ontario, for the year ending October 31st, 1911. Department of Public Works, Parliament Buildings, Toronto, Ont.

The Iowa Engineer.—Published by Students of Engineering, Iowa State College; $1.00 per year. Published monthly. Forty pages. Iowa State College, Ames, Iowa.

Report of the Sixth Annual Convention of the Western Irrigation Society, held at Kelowna, B.C., August, 1912. Forestry Branch, Department of the Interior, Ottawa.

Annual Report of the Board of Regents of the Smithsonian Institute, for the year ending June 30th, 1912. The Secretary, Smithsonian Institute, Washington, D.C.

Report of the Director of Forestry, for the Year 1912. Being Part 6, Annual Report, Department of the Interior. Issued by the Department of the Interior, Ottawa.

Preliminary Review and Estimate of the Mineral Productions of British Columbia, for the year 1912. Bureau of Mines, Parliament Buildings, Victoria, B.C.

Ice Cold Storage (on the Farm).—Bulletin No. 207. The Ontario Department of Agriculture, Parliament Buildings, Toronto. Fifty pages, with illustrations.

Castings.—Published monthly. A reference for buyers of foundry equipment and supplies. The Gardner Printing Co., Caxton Building, Cleveland, Ohio.

Journal of the American Peat Society.—Devoted to the development of American peat resources. Secretary, Julius Bordollo, Kingsbridge, New York City.

Report with Reference to Civic Administration and City Development, of the City of Prince Albert, Sask.—By E. A. James, B.A.Sc., and T. Aird Murray.

Telegraph Statistics, Dominion of Canada.—For the year ending June 30th, 1912. A. W. Campbell, Department of Railways and Canals, Ottawa.

Queen's Engineering Works Magazine.—Published by W. H. Allen, Son & Co., Limited, at the Queen's Engineering Works, Bedford, England.

Commercial Review Showing the Export Trade from Port of Montreal of Canadian Products in 1912.—The Gazette, Montreal, Canada.

Annual Report of the Directory of Forestry, for the year 1912. 270 pages. Department of the Interior, Parliament Buildings, Ottawa.

Training with Mine-Rescue Breathing Apparatus. By J. W. Paul. Bureau of Mines, Department of the Interior, Washington, D.C.

Chemical Properties of Western Larch.—By W. A. Ross, Department of Agriculture, Forest Service, Washington, D.C.

Board of Governors' Report of the University of Toronto, for the year ending June, 1912. Parliament Buildings, Toronto.

Mine Fires and How to Fight Them. By James W. Paul. Bureau of Mines, Department of the Interior, Washington, D.C.

Accidents from Falls of Roof and Coal. By G. S. Rice. Bureau of Mines, Department of the Interior, Washington, D.C.

Annual Report of the City Engineer of Port Arthur for the year 1912. Twenty pages. L. M. Jones, City Engineer.

Estimates for the Fiscal Year ending March 31st, 1913. Department of Finance, Parliament Buildings, Ottawa.

Chemical Properties of Western Hemlock.—Department of Agriculture, Forest Service, Washington, D.C.

Bulletin No. 62, of the University of Illinois, on the Electron Theory of Magnetism, Urbana, Illinois.

Mine Rescue Work in Canada.—By W. Dick, M.Sc., Commission of Conservation, Ottawa.

CATALOGUES RECEIVED.

D. VanNostrand Company, 23 Murray Street, New York, forward the following four catalogues and books: Catalogue of scientific books, recently issued and in preparation; catalogue list of books on Producer Gas and Gas, Gasoline and Oil Engines; catalogue of a list of books on Scientific Management, Efficiency and Allied Subjects; catalogue of scientific books published between December, 1909, and October, 1911.

Induction Motors.—Engineering Works of Canada, Limited, New Birks Building, Montreal, P.Q., operating under the patents of "Société Alsacienne Des Constructions Mécaniques," forward Catalogue No. 1, of 15 pages, on two and three-phase induction motors.

Dynamos.—From 200 to 15,000 horse-power, under construction in the shops of Belfort, by the Société Alsacienne de Constructions Mécaniques. Representatives in Canada, Engineering Works of Canada, Limited, New Birks Building, Montreal.

Switchboard Indicating Instruments. — The Northern Electric and Manufacturing Company, Montreal and Toronto, forward a catalogue announcement re Weston Alternating Current Switchboard Instruments. Write for Catalogue 16.

Catalogue of central stations installed by the Société Alsacienne de Constructions Mécaniques, Belfort, for mines and metallurgical plants. Canadian Rrepresentatives, Engineering Works of Canada, Limited, New Birks Building, Montreal.

Catalogue of book.—Title, Internal Combustion Engine, a handbook for designers and builders of gas and oil engines. By Hugo Güldner. 700 pages; 728 illustrations. D. VanNostrand Company, publishers, New York.

"Bitumastic" Enamel.—Wailes, Dove & Co., Limited, 5 St. Nicholas' Buildings, Newcastle-on-Tyne, agents, Montreal, Toronto and Vancouver, forward an 18-page little catalogue.

Portmadoc Slates.—Festiniog Slate Quarries Association, Portmadoc, North Wales, forward a 15-page catalogue and pamphlet on slates.

Lentz Engine.—Catalogue from the Erie City Iron Works, Erie, Pa. A Poppet valve engine under patent.

Blacksmithing and Drop-forging.—Tait, Jones & Co., Pittsburg, Pa., forward a 16-page catalogue.

COAST TO COAST.

Regina, Sask.—The Emerson-Brantarghain Implement Company, of Minneapolis, who are represented here by Tudhope-Anderson Co., recently shipped forty-five car loads of tractors here. This is claimed to be a record for the shipment of a single commodity, as the value may be seen from the fact that the freightage cost $7,145.

Ottawa, Ont.—The Canada Cement Company, the Canadian merger, threatens that the fullest advantage of conditions will be taken to obtain the highest prices possible for cement during periods of restricted supply, so that later it will be able to accumulate reserve to meet the importations from the United States at slaughter prices if the government re-enact the duty remission of fifty per cent. enforced from July 1st to October 31st, last year.

Winnipeg, Man.—The Grain Growers' Grain Company have purchased timber limits near Fort George, British Columbia, comprising about 300,000,000 feet of lumber, at a price of about $1.50 per 1,000 feet. It is said to be the intention of the Grain Growers to hold this as a reserve supply with the idea of establishing lumber yards at different points in the province for the purpose of supplying farmers and settlers with lumber at reasonable prices.

Ottawa, Ont.—Sustained growth and stability in Canadian trade are indicated by the figures recently published. The customs returns approximated $106,000,000, against $83,906,706 during 1911. Adding to this excise duties for the year amounting to about $31,000,000, the grand total is $137,000,000. The statistics for the year show that the total trade of Canada with other countries from January 1 to December 31, 1912, amounted approximately to a billion dollars, the imports being $650,000,000 and the exports $350,000,000. The total trade during the previous twelve months amounted to $828,614,120, the imports being $524,850,792 and the exports $303,763,328.

Toronto, Ont.—The new provincial boiler regulations have received their final approval, so that after July 1st every boiler manufactured in Ontario, apart from railway and steamer boilers, which are covered by separate legislation, must be made along standard lines and stand a thorough inspection, not only on completion, but during construction.

Ottawa, Ont.—Jas. Stewart & Company, one of the oldest contracting firms in the country, has been incorporated under the same name with a total capitalization of $3,750,000. It was formed in Ottawa in 1845 by Jas. Stewart, a native of Aberdeenshire, Scotland, and in 1865 moved its headquarters to St. Louis. It has district offices in Montreal, Chicago, Pittsburg, Salt Lake City and New Orleans. The new company's principal offices will be in New York, where they have $20,000,000 worth of business booked at present.

Before the conference committee of the Board of Trade of the city of Toronto last Thursday Mr. Lionel H. Clarke and Mr. E. A. James, chairman of and consulting engineer, respectively, to the York County Board of Highway Commissioners, presented some interesting phases of the work the commission has already done and is still doing. Mr. Clarke treated the subject of good roads from a general viewpoint, while Mr. James went more particularly into details, and outlined what had been accomplished, and spoke of some of the plans for the future. Following the address the meeting was thrown open, and Messrs. Gundy, Hewitt, Ellis and several others took part. Before the meeting adjourned a resolution was moved and carried unanimously, as a result of which the Board of Trade will continue its efforts to have legislation brought about which will result in the continuance of the good work already begun.

The old-established firm of Hyde & Webster builders' and foundry supplies, of Montreal, which firm has gone out of existence, have acquired the still older established business of Messrs. F. Hyde & Company, 31 Wellington Street, Montreal, and under the name of Webster & Sons propose to continue same business in all its branches.

PERSONAL.

MR. A. W. ROGER WILKY, C.E., for the past eight years on the engineering staff of the Island branch of the Canadian Pacific Railway, has been appointed engineer-in-charge of all construction work of the Department of Marine and Fisheries for the province of British Columbia.

MR. MORRIS L. COOKE, director, Department of Public Works, Philadelphia, Pa., on February 18th, delivered a lecture on "Scientific Management as Applied to Highway Engineering," before the graduate students in Highway Engineering at Columbia University.

MR. VIRGIL G. BOGUE, M.Am.Soc.C.E., former chief engineer of the Western Pacific Railway, has recently been engaged in an economic study of line improvement and double-tracking of the Canadian Pacific Railway through the Selkirk and Rocky Mountains in British Columbia.

WILLIAM McGIE YOUNG, B.Sc., Associate Member Canadian Society of Civil Engineers, graduate in mechanical engineering of McGill University in 1899, is leaving Ottawa to accept the position of comptroller of water rights in the Department of Lands of the province of British Columbia. Mr. Young was formerly chief engineer of the International Marine Signal Company, and has been recently practising as a consulting engineer, giving special attention to efficiency engineering, factory management and production.

HARRY WEBB has resigned his position with the city of Winnipeg to take up a position with the Canadian Mineral Rubber Company, Limited, as local manager, to succeed Mr. F. G. Pusey, resigned. Mr. Webb was in charge of the several paving plants operated by the city for five years, and during the last three years has been superintendent of all paving work in Winnipeg.

MR. W. W. COLPITTS, M.Am.Soc.C.E., a graduate in civil engineering of McGill University, class of 1899, and for three years associated with the Canadian Pacific Railway, has resigned his position of chief engineer of the Kansas City, Mexico and Orient City Railway to become associated with W. H. Coverdale & Co., of New York City. He is being retained by his former company as consulting engineer.

OBITUARY.

SIR WILLIAM ARROL, the most noted of British bridge builders, died on February 20 in London, Eng. He received his Knighthood in 1896, and was born in Ayrshire in 1839. He constructed the present Tay bridge and the Forth bridge. From 1895 to 1906 he represented Ayrshire in the Commons. He was a Unionist.

The Ontario Good Roads Association is holding its eleventh annual meeting at the Exhibition Buildings, Toronto, on February 26th, 27th and 28th of this month. Further notes of this meeting and the papers read will appear in next week's issue.

ONTARIO LAND SURVEYORS.

The following gentlemen received certification to practice as Ontario land surveyors at the recent examinations,—J. R. Gill, F. J. K. Benner, E. Cavell, R. F. Dynes, D. S. Ellis, S. E. Flood, C. W. G. Gibson, J. B. Hellferth, E. G. MacKay, D. A. Niven, G. L. Ramsey, W. R. White.

The following gentlemen have passed the preliminary examination:—K. Campbell, F. L. Moore, J. R. Scott, W. M. Stone, C. R. Yates.

COMING MEETINGS.

THE CLAY PRODUCTS EXPOSITION.—To be held in the Coliseum Chicago, Feb. 26th to Mar. 8th.

AMERICAN INSTITUTE OF CONSULTING ENGINEERS.—A meeting for the purpose of further discussing "Professional Relations," will be held at the Engineers' Club, 32 West 40th St., New York City, Tuesday evening, 8 p.m., March 11, 1913. Secretary, Eugene W. Stern, 103 Park Ave., New York City.

THE CLEVELAND ENGINEERING SOCIETY.—Regular meeting, Chamber of Commerce Bldg., March 11th, 1913. Illustrated Paper on "Storage Batteries," by H. H. Smith, Chief of Research Dept., Edison Storage Battery Co., Orange, N. J. Secretary, David Gaehr.

ILLINOIS WATER SUPPLY ASSOCIATION.—The Fifth Annual Meeting of the Association will be held at the University of Illinois, Campaign-Urbana, Ill., March 11th and 12th, 1913. Secretary, Edward Bartow.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.—Annual Meeting will be held March, 3, 4 and 5 1913, in the Green Room, Congress Hotel and Annex, Chicago, Ill. Secretary, Will P. Blair.

CANADIAN MINING INSTITUTE.—Annual Meeting will be held at Chateau Laurier, Ottawa, March 5th, 6th and 7th. H. Mortimer Lamb, Windsor Hotel, Montreal, Secretary.

CANADIAN ELECTRICAL ASSOCIATION.—Annual Convention will be held in Fort William, June 23, 24 and 25. Secretary, T. S. Young, 220 King Street W., Toronto.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, Phelps Johnson; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, R. F. Uniacke, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, A. R. Decary; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, E. A. James; Secretary-Treasurer, A. Garrow. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, G. E. G. Conway; Secretary-Treasurer, F. Pardo Wilson. Address: 422 Pacific Building, Vancouver, B.C.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P.O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton. Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta. Secy-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALTIES.—President, Chase, Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, F. P. Layton, Mayor of Camrose; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, R. W. Lines, Edmonton; Hon. Secretary, W. D. Cromarty, Edmonton, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Keillor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President, G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President, Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

TECHNICAL SOCIETY OF PETERBORO.—Bank of Commerce Building, Peterboro. General Secretary, N. C. Mills, P.O. Box 995, Peterboro, Ont.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, W. G. Mitchell; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

The Canadian Engineer

An Engineering Weekly

GREAT BRITAIN'S MIGHTY WARSHIPS

SOMETHING ABOUT THEIR ENGINEERING FEATURES

Photographic illustrations used by permission of the Right Honorable Winston Churchill, First Lord of the Admiralty, and supplied by courtesy of Messrs. Gale & Polden, Portsmouth, England.

Owing to the political situation in Canada at the present time, the navy of Great Britain is now very much before the public, and from recent actions, it might be intimated that the time is not far distant when the navy of Great Britain will be the navy of Greater Britain and become an imperial affair.

The columns of a technical newspaper are not a proper place to discuss the question from a political or patriotic viewpoint, but there are so many phases and aspects of the British navy and so little, apparently, known in Canada regarding its workings that it is but reasonable to assume that certain mechanical features will prove interesting reading to the patrons of *The Canadian Engineer.*

The fighting ship of today is a distinctly modern creation, and holds nothing in common with its predecessor excepting the ability to float. It is designed for one specific purpose, fighting only, and toward the accomplishment of that purpose the entire design is directed, but the following factors must receive due consideration:—

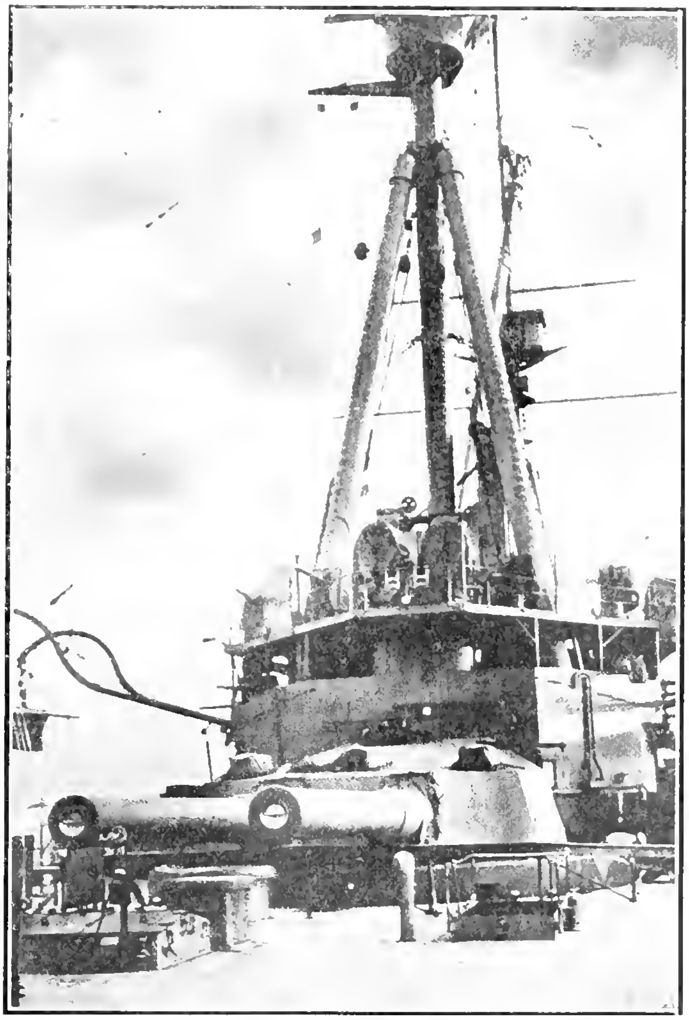
(1) The ship must carry sufficiently heavy armament to give a degree of striking power equal to anything that is likely to be met with in opposition during a time of action.

(2) The ship must have armor of sufficient strength and disposed about the vital spots in such a manner as to withstand sustained gun fire.

(3) The ship must have speed enough to enable it to manoeuvre against any hostile ship of its own type on terms of equality, if not superiority.

(4) The ship must be given sufficiently large storage of fuel—technically known as coal endurance—to enable it to keep the sea for lengthy periods and make long passages without the need of replenishing the bunkers.

(5) The ship must be given an ample ammunition endurance.



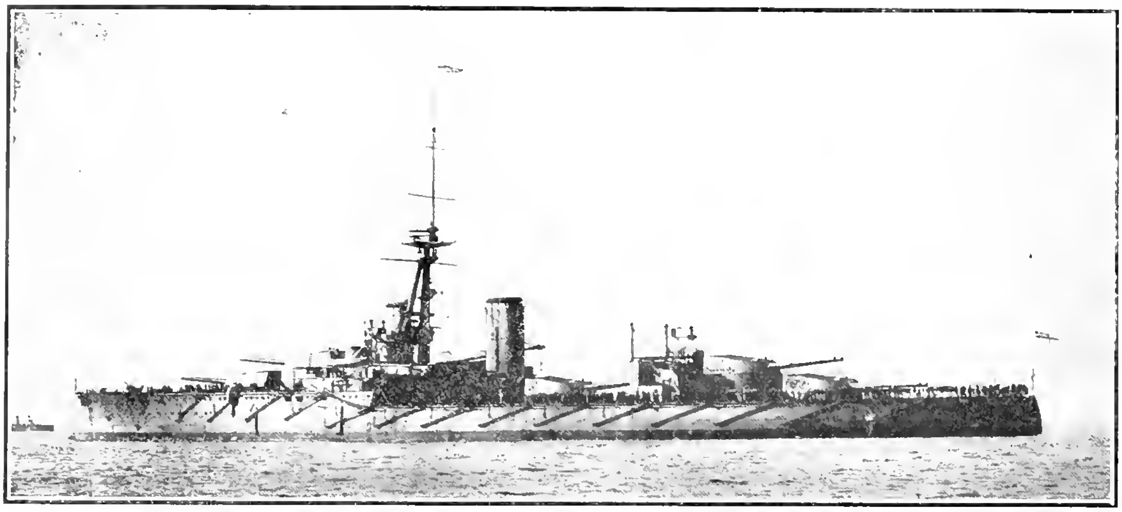
A Battery of Twelve-inch Guns and Their Fire Control Station in the Rear.

(6) The living quarters of the crew must be of the best, especially regarding sanitation.

(7) The ship must be absolutely seaworthy; this is the most important consideration of all, for after the entire matter is threshed out a battleship of the present day is only a floating foundation for heavy guns.

The naval designer has a difficult task before him when he attempts to reconcile all the foregoing conditions in the design of an ideal ship, as they are of such a contradictory nature, and if a battleship of given tonnage were armed more heavily than any ship previously afloat, the additional weight imposed by guns and mountings would have to be saved in some other point—in armor, for instance. The result of such a design would give a ship of great aggressive powers, but exceedingly limited in its own powers of resistance. If unusual speed is desired this involves increases in engine room, increased boiler space, and increased coal storage to maintain the steaming requisitions of the design. As the total tonnage is a given factor it follows that when one phase of the ship is made abnormal some other phase must be weakened; just which factor he may best reduce and in what manner the reduction may best be brought about are a few of the problems that the naval architect must contend. Some of these problems, however, solve themselves; an example will make this clear.

The battleships of the "Admiral" class which were much in vogue during the early eighties, were a type of ship that the admiralty hoped could be developed by enlargement in every detail as time and other conditions warranted; consequently this development continued until guns of 16¼-inch bore were mounted. It has been suggested that the corresponding increase in hull design was not thoroughly understood for of the three ships mounting these ponderous weapons, only one is on the sea to-day; this is the "Benbow." The fate of the "Victoria" is known to history, and the other member, the "Sans Pariel," is on the scrap heap. It was readily seen that development along this line was not practical, for the guns had a weight of 110 tons each, and this, added to their mountings, made the ship top-heavy, and then, again, this gun only possessed a muzzle energy equal to 2,087 foot-tons. The introduction of improved explosives and gun manufacture, which followed soon after the completion of these ships, resulted in an increase of efficiency of smaller guns, and in this manner the gun weight was reduced almost 50 per cent., with an increase of "smashing power."



H.M.S. "Orion,"
one of the most powerful battleships afloat.

The British warship differs from all other type of fighting ship in the degree of all-round fighting qualities. It is not so fast as a cruiser, and does not need speed: the object of a British warship is to get at the enemy, and not to run away.

Some few years ago, there was not such a marked line of separation between the battleship and the cruisers as now exists between the ships of the Dreadnought type and the modern cruiser. H.M.S. "King Edward VII." is probably the foremost example of a pre-dreadnought type of British warship, and yet the original "Dreadnought," though only 1,550 tons larger than the "King Edward VII.," has about 60 per cent. more smashing power and 33 per cent. more capacity of resistance, while several of the latest Dreadnought types could double these rates of increase.

With this rapid increase of power comes the rapid increase in the process of obsolescence, and twenty years is now regarded as the extreme maximum period of usefulness of a modern battleship; this short expanse of time is a marked contrast to the days of Nelson and his old wooden ships, for the "Victory" was fifty years of age when she entered the battle of Trafalgar, in 1805, and still floats in Portsmouth harbor, doing formal duty as the flag ship of the commander-in-chief of Portsmouth.

The primary business of the battleship is clearly indicated by the design, and the title and the work expected from a battleship squadron does not differ to any great extent, excepting the increased strength of the compound over the unit. It is a well understood axiom of modern sea warfare that however the course of the campaign may be influenced by brilliant desultory tactics, such as the guerilla attacks of cruisers and destroyers and such like, the great final issue may only be decided by the battle squadrons alone, and so long as they continue to float upon the sea the nation whose flag they bear is not beaten; when the battle squadrons are crushed the sea power of that nation is hopelessly broken.

Battleships form the first fighting line of all sea power. It is their duty to meet and engage, and all sea strategy is shaped to bring about this result on the most favorable terms. A meeting of hostile battleships may not of necessity be decisive, but when it is decisive and one side has no more effective battleships left, then the sea power of that nation is like the broken reed referred to in ancient history. The cruisers of a battleshipless nation may still manage to keep the sea and inflict serious damage to the commerce of the conqueror; and destroyers may make an occasional swoop with serious consequence, but the fact remains that without battleships organized sea warfare is at an end.

The power of the battleship then, depends upon its degree of gun fire and its resistance to hostile shells, and to maintain the latter condition the ship is armored; armor being a generic term embracing all the protective features of the ship. The principal heads under which the armor of a battleship may be classified are: (1) broadside protection; (2) armored bulkheads dividing the ship into watertight compartments; (3) protection of gun positions and all fighting stations, and (4) the protective deck.

The broadside armor is by far the most important feature in the defensive arrangements of any warship. It means the protection of engines, boilers and magazines against the direct impact of projectiles delivered broadside which, of course, presents the largest area of target to the guns of an enemy. In the modern designs the armor is carried from end to end and the greatest thickness is maintained along the central section which encloses the magazines and propulsion mechanism, the extremities are fairly thin. In a ship of the Dreadnought type this belt of armor is composed of a strip of Krupp steel, 11 inches in the thickest part and tapering to 6 inches at the forward end and 4 inches thick at the stern. A very much wider area of armor plate is always disposed below the water line than above; the belt being carried downwards to a depth of ten feet. Experience has shown that the high velocity projectile of a modern naval rifle, on being fired at a sufficient angle of depression to strike a ship well below the surface, either rebounds or becomes acutely deflected on touching the water. If the protective belt is carried to a depth of ten feet from the displacement line the chances of a ship being pierced from below are negligible.

The rapid improvement of naval guns rendered it im-

perative that the invulnerability of armor should be increased without a relative increase in weight; the Harvey process was the first step in this direction, but nearly all the British ships of to-day are armored with Krupp steel, which has a tensile strength of almost 50 tons per square inch, and is hardened by small injections of nickel, chromium and manganese. The Krupp plate, in its shell resistance qualities, has a figure of merit of about 2.5 as against 1.25 for compound armor which was supplied on armored ships built previous to 1890. The compound armor consists of a wrought iron plate attached artificially to a steel face of about half its own thickness; the result being a plate with the hardness of steel and the toughness of wrought iron on the back, the combination being designed to break a shell up without cracking the armor plate. Thus it is seen that the 11-inch belt of a modern Dreadnought ship offers more resistance to hostile gun fire than the 20-inch belt of the "Trafalgar" (a ship that was considered a wonder when commissioned in 1887) and this is accomplished with a reduction of about 47 per cent. in the weight.

In a modern British battleship a second section of broadside armor is carried above the belt mentioned above and is meant to protect the citadel or redoubt. This belt is carried upward from the midship section as high as the level of the main deck and is composed of 11 inches of Krupp steel in the centre tapering to 8 inches at the extremities; it encloses the turret mountings and the upper portions of the coal bunkers. All the main armor and the lower part of the upper belt is backed by a solid wall of coal nine feet thick.

The armored bulkheads subdivide the ship transversely into sections and these spaces are again subdivided by a central fore-and-aft bulkhead below the armored deck. In the Dreadnought type of British battleship the armored transverse bulkheads below the main deck—which is nine feet above the water line—are all unpierced excepting by pipes and wires and ingress and egress to these various compartments is effected by elevators.

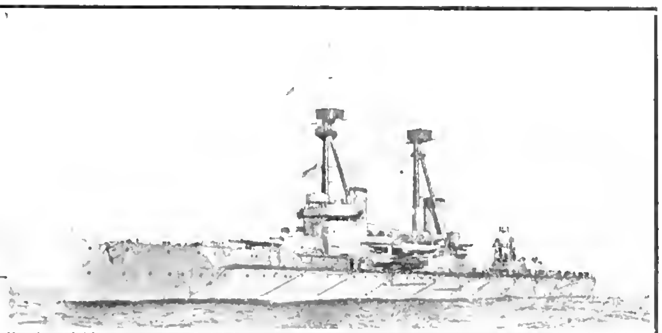
In the protection of guns the aim is to secure the maximum of safety for the crew and the firing mechanism, coupled with the greatest possible mobility in training the weapon over the widest possible arc of fire. The barbette, which is almost exclusively used in the protection of guns, is a circular fortress of steel with a bomb-proof top, the whole revolving upon a shaft which goes right down to the bed of the ship. (Fig. 1).

H.M.S. "Orion," considered to be the most powerful all-round fighting ship in service, mounts ten of the 13.5-inch gun of the new design. This gun weighs 76 tons and throws a projectile weighing 1,250 pounds with a muzzle velocity of 2,599 feet per second, and with the usual firing charge of 293 pounds of cordite is capable of penetrating 51¼ inches of wrought iron at a distance of 6,000 feet from the muzzle. It is reported that the admiralty have a still further improved 13.5-inch gun that has a muzzle velocity of 2,850 feet per second, and operates on a charge of 430 pounds of cordite without injury. This has not as yet been mounted, but according to report is an effective check against the proposed 14-inch gun mentioned in the estimates of certain foreign powers. The 12-inch gun, which we illustrate in Fig. 1, is the standard heavy British naval gun, and is mounted in nearly all the ships now in commission. This gun weighs 69 tons and throws a projectile of 850 pounds; the muzzle velocity of this weapon is 3,010 feet per second, and the extreme range is 25,000 yards, but its most dangerous range is given at 6,800 yards, at which point the velocity of the shell and its explosive properties harmonize to the best advantage.

A modern British Dreadnought carries 800 projectiles for these monsters, and the shell delivery apparatus is so arranged that one shot per minute could be flung from each gun. This rapidity of fire would not be feasible, however, owing to the eye-stinging vapors and the benumbing effect of the "back-blast" upon the crew. Guns of 10 inches, 9.2 inches, 7.5 inches and 6 inches are also disposed about the modern ship and all are considered large guns. The 4.7 and smaller weapons are regarded as "mosquito" armament, and are used only for close quarters, repelling torpedo craft, and by the marines when making land attacks.

H.M.S. "Invincible,"

one of a powerful line of battle cruisers that would keep the lines of commerce open during a time of hostilities, while the battleships were blockading the enemies' ports.



H.M.S. "Temeraire,"

one of many of Britain's latest Dreadnoughts. Note the tripod construction of the masts, they are constructed thus to allow great steadiness in the fire control tower situated half way up. Two legs of these supports could be shot away and the mast still remain rigid.

The fire control of each and every weapon on a modern British warship, excluding the hand rifles and officers' revolvers, is under the direct control of the gunnery officer in the fire control station. A series of electric wires and a switchboard enable him to communicate by telephone and other means with every gun turret on the ship. In order to reduce the risk of the fire control station from being shot away to the smallest possible limit, the fire control station is mounted on a steel tripod, each leg of which will effectively support the platform for a time, should the other two members become damaged. These tubes are hollow and the station may be reached by ladders secured to the inner surface.

The cost of a modern super-Dreadnought may be taken as follows:—

Hull	$2,386,000
Boilers and machinery	2,000,000
Searchlights and electrical fittings	400,000
Boats	40,000
Armor plate	3,240,000
Five barbettes and ten guns	3,000,000
Secondary armament of six-inch guns	400,000
Five torpedo tubes	200,000
Total	$11,666,000

PLANT EQUIPMENT.*

By F. E. Ellis.†

A score of years ago road building was a very simple business, requiring only a small amount of plant and very little expense was incurred by anyone who wanted to enter into it, and one in the business could withdraw from it at any time without sustaining a great loss due to the amount of capital tied up in the plant. During the last twenty years, the method of road building has gradually changed, until the plant now required by a contractor is large and varied, and the expense attached thereto is enormously large in proportion to the amount of work done per year.

It has become a business in which one should not enter without considering thoroughly the kind and amount of equipment required to do the work that he is contemplating, and only after a careful estimate has been made of the expense of plant and the proportionate charges that should be made for the same upon the work on which he is bidding. One must also realize that once in the business, he must remain in it for many years in order to get back the cost of his equipment, or else be willing to take a loss on the sale of it upon retiring. In other words, it is not a business that a man should enter upon with the idea of its being temporary, but with the idea of its being permanent. Failure to understand or obey this principle has been disastrous to many contractors. If the proper plant charges are not made, the contractor is deceiving himself just as surely as did the kind old lady who gave gingerbread to all the children in the neighborhood, and thought it did not cost anything because she had everything in the house to make it of.

The kind and amount of equipment which is required for building a road will vary in the different classes of roads to be constructed, and in order to make a correct estimate of the cost of equipment and the expenses incidental thereto, it is necessary to know the class of road which is to be built. For example, I am going to show you just what it actually costs to equip a road with proper construction plant. The road built was six miles in length, and surfaced with local stone grouted with bituminous binder. The stone was obtained from a quarry which was situated so that the average haul was about two miles. The whole contract amounted to $60,000.00. A contract of this size is considered an average season's work for one gang of men and one set of equipment. I am going to omit from these calculations the cost of small tools, such as picks, shovels and scrapers, and confine myself to larger items of wagons and machinery. The total cost of equipment was $18,240.00 or 30 per cent. of the contract price. The interest on the cost of equipment at 6 per cent. and depreciation at 10 per cent. per year makes a total of $2,918.40 for fixed charges on equipment, necessary to do $60,000 of work per year, or approximately 5 per cent. of the amount of the contract. Most of the expense of equipment was chargeable only to a few items in the contract which included the surfacing. The contract price for these items amounted to approximately $32,000. The first cost of the equipment used in the work covered by these items was $16,445 or 51 per cent. of the work done. The interest and depreciation upon the same amounted to $2,631.20, or 8.2 per cent. of the amount of the work done.

This I believe to be a fair estimate of the amount of equipment and the charges which should be made in order to be safe in estimating upon work of this character. There is hardly any business conducted in which the investment for equipment is so large and the expense due to depreciation and upkeep so great as in road building. Every engineer and contractor in making estimates ought to take these charges into consideration, and contractors who expect to go into the road building business, should make a careful estimate of the amount of plant required and the expense attached thereto. It is not a business in which a man can expect, in these days of keen competition, to make enough profit to pay for a plant in one season's work, and a man entering upon this kind of work must expect to stay in the business a long time before the equipment can be paid for out of the earnings. Road building machinery should only be purchased after a thorough investigation, especially in regard to the liability of breakdown and the expense of the up-keep. The expense of repairs on road building machinery is very small in comparison with the loss which is occasioned by the disorganizing of working crews due to breakdowns. In deciding upon the purchase of machinery, too much weight should not be given to the item of first cost, as the more expensive machine in first cost may be a far cheaper machine to operate and may be depended upon to do its work day in and day out, where a cheaper machine, although it may not break down, is very liable to do so.

In this discussion of road building equipment, I am not going to make any recommendation. I do not expect that my remarks will meet with the full approval of any of the machinery men or the contractors. We all know that if a man purchases an automobile that whatever kind he purchases, be it a one-lunger or a six-sixty, that particular kind is the only automobile worthy of consideration, and it can travel more miles per day than any other make, with less gasoline and expense of up-keep, and the same views are taken by a man who purchases road building machinery. I am therefore only going to give you my own views, which are the result of personal experience.

Wagons.—Four kinds of wagons have been largely used upon road work. The four-wheeled bottom dumping wagon, the four-wheeled two-horse tip cart, the two-wheeled one-horse tip cart and the four-wheeled slat wagon. The slat wagon offers no advantages over the other type, except they are a little lower and easier to load. This advantage is altogether outweighed when the time lost in dumping and turning around is taken into consideration. The single horse tip cart is very economical on short hauls and for work in contracted space, and for making end and side dumps on embankments, or in hauling stone from the quarry to the crusher. The four-wheeled tip cart hauls and is handled very easily on road work, but the weight being all on the hind wheels it is very destructive to road surface and sub-grade, and much time is lost in dumping and righting the wagon. The bottom dump wagon can be used anywhere that the two-horse slat wagon or tip cart can be used, and is more economical than either, the expense of maintaining roadway being very much less than with the other kind. Material can be dumped more quickly, it not being necessary to stop while dumping, and the material can be distributed to a better advantage than with any other type of wagon. Any wagon used on road work should have tires not less than four inches wide.

Road Machines.—A road machine can be used to advantage in digging side ditches, scraping shoulders and making light cuts in the roadway. A machine for this purpose should be built strong enough to be hauled with a steam roller or traction engine without danger of breaking the machine, and also be equipped with a steering device, so that the machine may be worked outside of the travelled roadway

* From a paper read before ninth annual convention of American Road Builders' Association, held at Cincinnati, December, 1912.

† Manager, Essex Trap Rock and Construction Co., Peabody, Mass.

while the roller or traction engine is working upon the firm travelled way.

Stone Crushers.—Three types of stone crushers have been used to a great extent in road building—the gyratory type, the jaw type of the Blake pattern and the jaw crusher of the cam-shaft and roller type. The gyratory type is not very well adapted for portable plants on road work, as the crusher opening is so narrow that the stone requires too much sledging in order to properly feed to the crusher, and the crusher opening is so far above the ground that it requires either a pit or an extremely high dumping platform with a long incline in order to get the stone into the mouth of the crusher. They are also complicated and expensive to keep in repair for work in the eastern part of the country, as it is a long way from the source of supply of the repair parts. For permanent plants where the stone breaks well in blasting, they are a very economical machine.

The advantages of the Blake pattern are the extreme simplicity, there being a less number of reciprocating parts and a less number of bearings which require oiling, than in any other crusher. There is a wedge adjustment by which the crusher opening may be regulated without stopping the crusher. This is an important feature, where enough fine stone must be dumped along the shoulders of the road ahead of the bottom course, as in the case of grouted bituminous work. There is only one tension rod and one spring to keep in adjustment and repair. There are no bearings into which stone clips and dust are liable to enter. This type of crusher I have found to be very economical to maintain and is extremely reliable.

The disadvantages of this type are that for the same size opening, the crushers weigh more than the other type of jaw crushers. They are not so easily transported and handled, the situation and size of the fly wheels in reference to the crusher make it more unhandy to dump close to the crusher than any other type. As a rule the first cost is in excess of the other type of crusher.

The advantage of the cam shaft and roller type crusher is its light weight, which makes it easy to transport and set up, low fly wheels, situated so that the stone may be dumped much closer to the crusher opening than in the Blake type, low first cost and the quick delivery of repair parts. The disadvantages are that it is much more complicated; has more moving parts, more springs and tension rods, than the Blake type. There are more bearings to be lubricated, and the toggle lever shaft is generally situated so that chips and dirt can enter into the bearings. No adjustment can be made regulating the opening of the jaws without removing the toggle which can only be done by shutting down the crusher. Both crushers of the jaw type here mentioned will produce about the same amount of stone for the same size receiving opening and require about the same horse-power to run. All crushers should be fitted with manganese steel jaw plates, as experience has shown that these plates will last about three times as long as the first-class chilled iron plate, and are unbreakable, whereas the chilled iron plate may break or wear out in pockets after running a very short time.

Most all the crusher manufacturers make complete plants composed of bins, crushers, elevators and engines, which are mounted on wheels and can be loaded upon freight cars without being knocked down. Plants built in this style are very economical to handle and set up and are adapted to nearly all kinds of work requiring crushed stone. Where a traction engine is used for hauling stone away from the crusher, it is more economical to have larger bins and longer elevators than are generally furnished with a strictly portable outfit, as it is necessary to have storage capacity in the bins large enough to load a train of traction cars without waiting for the stone to be crushed. On a good many of these portable outfits, the screen plates and elevator buckets are made of too thin material to wear well, the elevator buckets wearing and rusting away quite rapidly. Unless specially ordered the sprocket wheels and gears are usually made of cast iron. The small sprocket wheels and beveled gears, I think, should be made of manganese steel.

Crusher Engines.—Crusher engines should always be large enough to have a surplus of power over and above that which is ordinarily required to run the crushing plant, and the boiler should have additional capacity large enough to supply steam for a steam drill, as in a great many cases, if this is not done, an additional boiler will have to be provided. Most of the states have laws which govern the construction and inspection of boilers, and in the states that have no laws now regulating the construction of boilers, the question is being agitated and undoubtedly in a few years there will be such in most of the states, and as road building has become quite an interstate business, and the machinery is transported from one state to another, care should be taken to procure a boiler which will pass state inspection. I believe that any boiler which is built in accordance with the Massachusetts standard can be used in other states, but there are many boilers which can be used in other states which cannot be used in Massachusetts. Plants equipped with boilers built to the Massachusetts standard, will cost more than boilers usually furnished with crushing plants. These remarks apply as well to road rollers, or any boilers.

Hauling Engines.—Where there is enough work to keep a hauling engine busy and suitable provision can be made for loading and unloading quickly, a hauling engine may be used to advantage, and is about 50 per cent. cheaper than hauling with horses. There is still an opportunity for improvement in hauling engines, especially in regard to gearing and traction wheels, most of the makers using cast steel gears that are uncut and very rough, and which wear very quickly. They also use a built-up riveted or bolted wheel with rolled steel rim. These wheels are generally a source of trouble, as the spokes get loose and break where the travelling is rough and stony, as it is on most construction work.

Road Rollers.—There is no class of machinery used in road building in which there is so wide a difference in construction and design and first cost as in the steam rollers. They may be obtained in most any shape or size or design that can be thought of. I think that it is generally conceded by road builders, and it has been my own experience, that a double cylinder steam road roller is better adapted for road construction than any other type. There is no class of road building machinery which has been so highly developed. The wide variation in first cost of the different steam rollers makes it very difficult for a contractor or town official to make up his mind which one ought to be purchased. There is almost as much difference in road rollers as there is in watches. You may purchase a watch for a dollar which is liable to keep good time for a year and it is liable not to do so. You may purchase a watch which costs almost any price, and in every case you will probably get just what you pay for. As a general thing, the higher the price up to a certain limit, the more dependable the watch is, and the same rule applies to road rollers. There is no road building machinery sold, that I know of, upon which an exorbitant profit is being made. In looking over a road roller with the view of purchasing, particular attention should be given to an investigation of the gearing and wheels. You can tell by the looks of the wheels and gears upon the machine which has been in use, whether or not that machine is going to do your work day in and day out as it ought to. A set of rear wheels should last, under ordinary service, at least ten years. I have wheels which have been in service fourteen years and

are good, I think, for one more. The gearing on steam rollers should be of steel and cut and fitted as nicely as in any high-class automobile construction. Gears should be closed so as to exclude dust.

This paper might be extended indefinitely, going through all the different kinds of machinery required for the different kinds of road work, but I am going to conclude, as I have touched upon the equipment that is common to all road construction, whether it be water-bound macadam, bituminous macadam or concrete.

THE V-NOTCH WEIR METHOD OF MEASURING WATER.*

By Robert Yarnall.†

Attempts to measure accurately and to record automatically the flow of water through pipes or channels have been made from time to time with varying results as to accuracy and convenience. This paper will attempt to show results obtained by the simple and practical V-notch method of measurement, which though not new, seems now to be meeting with marked success, both abroad and in America, in power plant measuring problems. Tests of the accuracy of this method of measurement have recently been made in America and the data collected are here presented to show the degree of accuracy attainable.

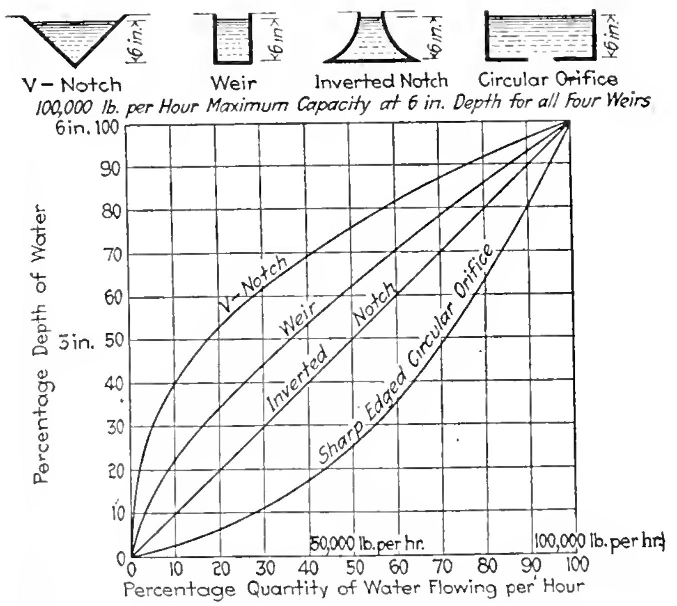


Fig. 1.—Curves Showing Comparative Accuracy of Different Types of Weirs Under Different Rates of Flow.

The instrument employed in the tests is the Lea V-notch recorder, an apparatus which depends on the laws governing the flow of water through weirs. These laws have been found to work with extraordinary accuracy, but it is only comparatively recently that they have been turned to account in measuring the widely varying rates of flow, both hot and cold, met with in power plants.

The most common forms of weir are the plain horizontal sill and the sharp edged rectangular notch. The former of these has the full width of the stream or channel and is without end contraction, the formula used in connection with it being that of Francis:

$$\text{cubic feet per second} = 3.33\ LH\ \sqrt{H}$$

where

L = The width of the weir in feet.

H = The head of water passing over it in feet.

The latter is a sharp edged rectangular notch of less width than the channel or stream and therefore has end contraction. The formula used in this case is

$$\text{cubic feet per second} = 3.33\ LH\ \sqrt{H} \times C$$

where

L and H are the same as before.

C = a constant which depends on the ratio of the width of the weir to the width of the channel.

Although these two formulas give a fair degree of accuracy, there is another in which the accuracy is very nearly 100 per cent. This is Prof. James Thomson's formula for the sharp edged V-notch weir:

$$\text{cubic feet per minute} = 0.305\ H^2\ \sqrt{H}$$

where

H = The height of the notch in inches, the angle of the notch being 90°.

Table I. gives the flow of water through 90° V-notches for each inch of head, up to and including 15 in., calculated by Thomson's formula.

Table I.—Flow Through 90° V-Notch Weirs.

Depth in notch, in.	Flow per hour, lb.	Depth in notch, in.	Flow per hour, lb.
1	1,140	9	277,900
2	6,480	10	361,740
3	17,830	11	459,030
4	36,610	12	568,720
5	63,940	13	694,710
6	100,860	14	836,110
7	148,290	15	993,510
8	207,060		

The section of the flow through the V-notch is at all times the same shape, though the area may vary, and this constancy of form tends to simplify the formula and make it accurate. This form of notch is also especially adapted for measuring smaller quantities of water than the rectangular weirs, as shown by the curves in Fig. 1, which give a comparison of the accuracy of the different types of weirs at different rates of flow. Another property of the notch is that its angle may be less than 90° without impairing its efficiency, which enables it to be used to measure very small quantities of water.

It was for these reasons, as well as for its accuracy, that the V-notch was adopted for use in connection with the Lea recorder, a sectional view of which is shown in Fig. 2. It will be seen that a float spindle, rigidly attached to a float which rides on the surface of the water flowing over the V-notch, passes up through the bottom of the instrument case. A rack on this spindle engages a small pinion upon the axis of a drum revolving between centres. Upon the body of the drum is a screw thread, the contour of which is the "curve of flow" for the V-notch in connection with which the recorder is used, and as the flow through the notch increases rapidly with the depth, the pitch of the screw increases in the same proportion. Above this drum is a horizontal slider bar, supported on small pivoted rollers and carrying an arm, at the upper end of which is a pen or pencil point in contact with a paper chart upon a clock-driven recording drum, which revolves once in 24 hours. As the float rises or falls the drum spiral is rotated, and its motion

*From a paper read before the American Society of Mechanical Engineers at its annual meeting in New York City, December, 1912.

†Mechanical Engineer Yarnall-Waring Co., 1109 Locust St., Philadelphia, Penn.

is imparted to the slider bar and pen arm by means of a saddle arm projecting from the latter and engaging at its lower end with the screw thread. On the body of the spiral drum is a graduated scale adjacent to the screw thread and computed in pounds per hour. It is thus seen that the drum serves the double purpose of rectifying the motion of the pen so that it moves equal distances for equal increments in the rate of flow, and of providing a magnified scale for making an accurate observation of the rate of flow at any moment.

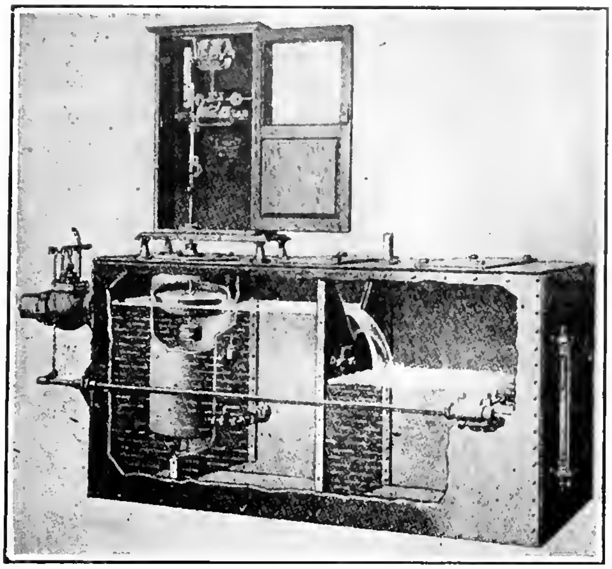

Fig. 2.—Sectional View of V-Notch Weir Meter with Lea Recording Mechanism.

The apparatus has the following advantages:

a. It is simple and hence dependable.

b. Its operation is continuous.

c. There are no moving parts in contact with the flow except the float which is in a chamber by itself and not in the path of the flow.

d. Collections of sediment and deposits of scale do not affect the accuracy.

e. Owing to change of density of the liquid being measured, due to changes in temperature, the float which actuates the recorder is immersed more or less, depending upon this change of density, and the recorder and the float are so constructed that they compensate automatically for these changes in temperature over a wide range.

f. By making the tank of ample proportions a considerable interval of time takes place between changes in the head on the weir, so that the recording apparatus has a chance to adjust itself to changes in the rate of flow, thus giving a chart very easy to measure with the planimeter.

g. It is always placed on suction side of pump, hence it is available at all times for inspection, cleaning and repairs.

Like the Venturi meter and the Pitot tube, the V-notch recorder is a continuous flow meter, but unlike these it is not dependent for its accuracy on velocity changes, and hence its record is not subject to the fluctuations due to sudden changes of velocity head observed in these meters while measuring rapidly changing rates of flow. Perhaps the greatest advantage of this method of measurement is found, however, in the way by which it may be checked independently of the recording mechanism. The operator may construct alongside of his recorder an independent "hook" gauge or use the graduated vertical scale and pointer on the extended float rod in the instrument, and can observe from time to time the number of inches head on the weir. By substituting these values in Thomson's formula, the rates of flow as shown on the recorder chart may be checked quickly and accurately. Thus the operator need not depend upon the recorded result until he is sure that it agrees with the

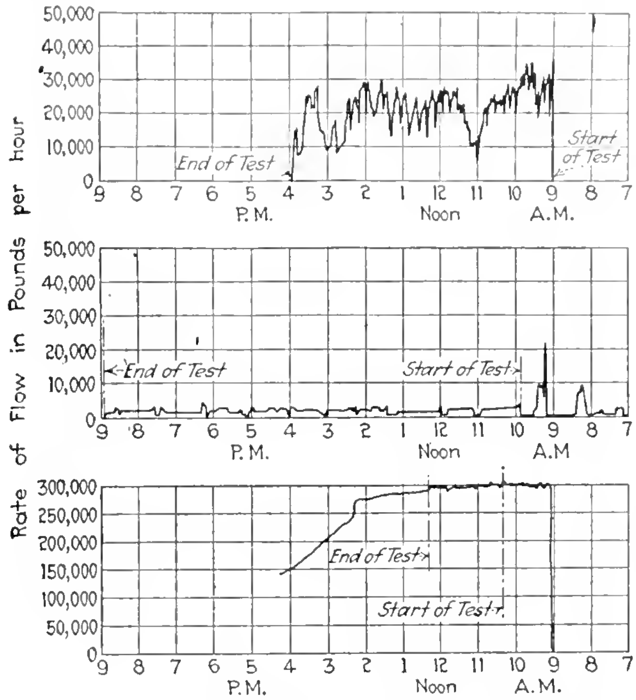

Fig. 3.—Records of Tests on V-Notch Weir Meters.

figured result from his hook gauge readings. It is believed, therefore, that the V-notch with its tank is the most satisfactory testing set that could be devised for measuring water under varying conditions of temperature, continuity of flow, and rate of flow.

The tests mentioned in the opening paragraph of the paper were made at Dartmouth College, Philadelphia, and

New York City. At the first location there were two tests, one in the winter and one in the summer, conducted by the engineers of the college, Messrs. R. D. Kimball Co. The graphic charts of these two tests are shown in Fig. 3, where the top chart shows the record of the winter test, the middle chart that of the summer test, while the record of the Philadelphia test is given in the lowest chart.

The winter test at Dartmouth College was made at the normal running load and took care of all the natural fluctuations in the returns from the heating system, which was being taxed to its utmost by an outside temperature only slightly above zero. These fluctuations were due in part to poor control of the return water from the heating pipes at the new Gymnasium, and in part to the small water-storage capacity of the receiver. The summer test was later run with the same apparatus as the first test, but the rate of flow and amount of fluctuation were greatly reduced because the Gymnasium heating system was out of service. The Philadelphia test was made with water of considerably lower temperature and much higher rate of flow. Also in this case the amount of fluctuation was comparatively negligible. The tests at New York were of longer duration and employed a meter of the larger capacity used.

In Table II. is shown the comparison of the principal data obtained in these three sets of observations and from this table it is apparent that the V-notch weir method of measurement, using the Lea recording mechanism, can be depended upon to within about 1 per cent., even in extreme cases of fluctuating character of flow and changing temperature.

ONTARIO'S SALT SUPPLY.

The brine wells of the south-western peninsula of Ontario last year yielded 88,689 tons of salt, the value of which was $430,835. In 1910 the output was 84,071 tons, worth 414,978. The industry gave employment to 216 workmen, whose wages amounted to $121,477. There is a steady demand for this staple article, mainly for preservative purposes connected with food products, etc., but this demand is easily satisfied and does not seem to be increasing. Its requirements are small in comparison with the abundant supplies of raw material, which is present in enormous quantities. Salt constitutes the basis of a number of products of great importance in the industrial arts, connected with one or other of the elements composing it. From chlorine may be built up hydrochloric acid, bleaching powder and a variety of other articles, while the compounds of sodium, such as carbonate and bi-carbonate of soda, sodium nitrate, etc., play perhaps even a larger part in manufactures, states the statistical review of the Bureau of Mines, compiled by Mr. T. W. Gibson, Deputy Minister of Mines. A plant for the manufacture of caustic soda and bleaching powder from salt was established at Sandwich by the Canadian Salt Company, and began operations during the last week of 1911. Some inquiry has also been made on behalf of a European firm of explosives manufacturers as to the availability of salt supplies required for the sodium nitrate used in making their product, which is finding a market in the mines at Cobalt.

About one-half of the salt made in Ontario is produced by the Canadian Salt Company, whose plants are at Windsor and Sandwich. Other makers are the Dominion Salt Company, Sarnia; Western Canada Flour Mills Company, Goderich; John Ransford, Stapleton; Ontario People's Salt and Soda Company, Kincardine.

The workmen employed at the salt wells and works numbered 216, and their wages amounted to $121,477.

SKYSCRAPERS ARE MONEY-LOSERS.

Mr. Purdy, president of the Department of Taxes and Assessment, New York City, spoke as follows of high buildings while in Canada lately, before the Canadian Club of Toronto.

Rising out of the present-day tendency to tax land fully, Mr. Purdy said, had come the tendency intensified to put real estate to that use which would make it yield the greatest financial return, but as yet the cities of this continent have failed to realize the necessity of protecting men's liberty against the license of their neighbor—hence the "skyscraper.". Through the failure to restrict both the height of office buildings and the proportion of ground covered by them, light and air had been shut off to the extent of depreciating the value of the properties in the district, while high land values had also been localized in an extremely small area of the down-town district.

Preserve Air Space.—In his official capacity, the speaker had sat at the hearing of some 50,000 applications for lower assessment, and the number of these which were based on the loss of light and air through the disproportionate height of buildings in relation to surface area was astounding. Closely packed tall buildings had resulted in discomfort to the occupants, which caused them to forsake them, and the appeal for lowered taxation had followed. He further attributed to the intense congestion brought about by the erection of such structures, the smallness of the business area where land values are really high. At one point on Broadway, he explained, corner lots 25 by 100 feet in area are worth over one million dollars, while less than 100 yards distant are similar lots which would not command $25,000. "Had we restricted the height of buildings as did the cities of Europe," he declared, "we would have no $25,000 lots, no three-quarters of our business people working by artificial light during the day time, and no streets so crowded that at lunch and supper time it is practically impossible to walk in the opposite direction from the crowd."

As a preventive, he recommended legislation controlling both the height of buildings and the percentage of the lot which they may cover, in order that air spaces may be left between them.

"May I commend you," he continued, "here in this great growing city, which is still in such a position that you can regulate it in time, to look at the pictures of German cities, and to read their building regulations. They are restricting building from the standpoint of utility on the principle that no building may be allowed which will prevent others of the same size around it from receiving their share of light and air."

He further stated that he had recently had opportunity to talk to those who have erected one after another of the recent skyscrapers in New York, and not one of them has made money. Other arguments may not be effective, but perhaps this statement may give pause to some of those who wish to rush you into the erection of large office buildings which are to be the highest in the British Empire.

More Intensive Use of Land.—"With an increase of the tax on land has been an increase in the endeavor to use land for the most intensive purposes," the speaker continued. "Most European countries have recognized that it is necessary to impose the most stringent rules to regulate the height of buildings, and the area of land to be used for office buildings. Both the United States and Canada have been backward in imposing such regulations. They have been loath to impose regulations which would hamper the individual, but perhaps they have overlooked the fact that the freedom of the individual is bounded by the freedom of others, and

that no individual should be permitted to do those things which interfere with the rights to light and health of his neighbors.

Restriction Injures City.—"The city of New York has suffered by this false idea. The limit to the erection of buildings has reduced the value of adjacent properties as a result of this license. We have ruined the appearance of the city, and impaired the health of its citizens, only to reduce the number of its suitable office buildings. Also, we have rendered it practically impossible to get any commensurate value from a great number of lots which are surrounded by these buildings of great height which have shut off their neighbors from light and air which they require.

"German and English cities have enforced ordinances which it would be well for American and Canadian cities to copy. The fact of the matter is that so far as New York is concerned, we have allowed ourselves to reach a condition which is without remedy. I speak now of the Borough of Manhattan. We can still help outlying boroughs, and you have opportunity to help a city which is growing logically and sensibly, but which you should not permit to depend for growth on artificial means."

PRACTICES OF THE WORLD'S BANKS

BY M. P. LANGSTAFF, A.I.A., F.A.S.

As has been the rule, the rate of discount announced by the Bank of England from time to time serves as a guide to the other banks throughout England and Scotland in fixing their rates for loans and deposits. It is, indeed, in a position to compel other banks to raise their rates to the same extent; for, should the London joint stock banks, for example, continue lending at a lower rate, the Bank of England would proceed to borrow all floating money that could be found on the security of consols, and thus create a vacuum, which could be filled only by money from foreign countries.

The Bank of England is the banker of the Government; is the largest issuers of notes, issuing its notes when required in exchange for gold bullion and paying notes in gold coin; and, being the bankers' bank, the weekly returns as to its position form the best possible barometer of the state of trade and credit in the country.

London has often been referred to as the clearing house of the world; for here many of the largest traders make their settlements; here the world's supply of gold finds its natural point of distribution; and here, England herself makes her great loans of capital. The Bank of England, therefore, is the centre of a great system of joint stock and private banks doing an immense cosmopolitan business. These banks keep their chief reserves in the Bank of England, which necessarily, therefore, occupies a position of great responsibility. From the peculiar nature of the business done by these banks, it follows that their liabilities are affected by numerous and sometimes unexpected conditions, whether in England or in any foreign country of importance, and hence they must often find themselves subject to great and sudden demands, which react, of necessity, upon the Bank of England, in which they keep the major part of their reserves. It is seen, therefore, that the Bank of England holds in its charge that on which the solvency of the banks in general, the safety of the commercial public, and the credit of England alike depend.

It has been said that in Scotland credit has been systematized to the last degree, and in this connection it will not be out of place to refer to their system of "cash credits." These, while not directly affecting the money market, perhaps, have yet from the fact that they have played an important part in the development of agriculture in Scotland, tended to affect it in their reactionary and future results.

When a borrower obtains a cash credit from the bank he is permitted to draw money as it is wanted up to a certain sum, being charged interest only for the time and on the amount actually used. As a cash credit is not based upon any completed commercial transaction, it is in reality "accommodation paper." For this reason adequate personal security in addition to that of the borrower is required, the bank thus advancing the loan on its knowledge of the character of the borrower and of the responsibility of his endorsers. Owing to this system, many young men of ambition and character have been enabled to attempt praiseworthy enterprises without the necessity of waiting long years to accumulate money from their own earnings.

If we consider the vast number of securities discounted by the Bank of France and their small average amounts, it must be at once apparent that the bank is a lender on a large scale to the class of small traders. One reason for this is that the bank discounts a great deal of paper on which advances have already been made by the banking house, which are the immediate customers of the bank.

Owing to the policy of the bank in lending in this way to intermediaries, and also direct to the small borrowers themselves, these latter are enabled to derive much advantage from the relief afforded by the maintenance of a fair rate of interest due to this flow of loans at a steady rate from the bank. The bank has also found by experience that the business carried on with the class of small traders is singularly free from loss and generally steady in its movement. Owing therefore, to this class of business, and also to the advantage that it enjoys as a debtor, under the bimetallic system of the Latin Union, the Bank of France has become in specie holdings the strongest bank in the world, and is less affected in times of financial stringency than any other bank.

I have referred before to the elasticity allowed to the Reichsbank in its note issue. Owing to this "elastic limit" it is enabled in a time of financial stringency, when the demand for loans is imperative and the market rate is high, to meet the necessities of borrowers, aud thus quiet the public mind.

Like the Bank of England, the Reichsbank holds a large percentage of the reserves of the other banks. As a consequence, the German banking world is dependent upon it in the event of any extrtaordinary demand. Occupying, as it does, the central position in the German money market, the Reichsbank finds it necessary to be ever on its guard against the dangers of the depletion of its reserve; and a diminution of this reserve is not only regarded with concern by the banking world, but becomes a matter for general uneasiness from the fact that this reserve is regarded as a most important resource for the Empire in time of war. Like the Bank of England, the Reichsbank regulates this reserve by varying its rate of discount, and, as a general rule, seems to have experienced less difficulty than the Bank of England in bringing the outside rates of the general money market up to a close approximate of its own rates.

Under the operation of the reserve system the cash reserves of the national banks are centred in New York. The great structure of bank credit in the United States, resting as it does in a large measure upon the money reserves of the New York banks, has been analogized to an inverted pyramid upon its apex. Financial conditions throughout the whole country are affected by every important fluctuation in the New York money market; and, similarly, the New York money market is affected by every change of any consequence in the demand for money or credit in any part of the country

Great economy in the use of money is the result of the central reserve system, the use of which, however, in the

United States seems attended by certain dangers; but the reasons for these may be assigned to other features of the United States banking system, among which may be mentioned the dominance of speculative influences in the New York money market, the independent Treasury system, and rigidity of the bank note issues.

To the fact that Canadian banks refuse to encourage speculation to any extent whatever may be assigned the comparative steadiness of the Canadian stock markets.

I have before referred to the tendency towards equalization of the rates of interest in all parts of the Dominion, due largely to the branch system and freedom of note issues of the Canadian banks.

THE RATIONAL USE OF WATER IN IRRIGATION.*

Dr. John A. Widstoe.

To all who have dipped ever so little into the history of irrigation, the annual meetings of this Congress appear of great importance. Irrigation is one of the great world-movements for subduing the "waste places" of the earth, and also for solving many of the social problems that perplex mankind. It is not impossible that upon irrigated lands, with their possible small family units, and their fertile soils and abundant sunshine, shall be formulated by actual experience the social ideals that eventually may bring the nations with their legions of human hearts into co-operative peace. This Congress is the only organized body which assumes general interest in all the methods, purposes and results of irrigation.

From its humble beginning in this city, modern American irrigation has grown, until the census of 1909 reports nearly 14,000,000 acres of irrigated lands. One-half of this vast area was brought under irrigation since 1899, and three-fourths since 1889. That is to say, during the last twenty years, three-fourths of the irrigated lands were reclaimed; while only one-fourth was brought under irrigation during the first forty-two years after the entrance of the Utah pioneers into the Great Salt Lake Valley. Clearly, the efforts of the country in behalf of irrigation have increased in geometrical ratio. This interest appears to continue undiminished, so that it can only be a matter of comparatively short time until most of the irrigation waters of the West shall have been brought upon the lands.

There are three main stages in the development of an irrigation project. First, the construction of satisfactory dams and canals in which the water may be stored and then led upon the land; second, the settlement upon the reclaimed land of a sufficient number of people to make full use of the opportunities of the project; and third, the correct use, by the settlers, of the water and land so that the project may be highly and permanently profitable. While these three stages are of equal necessary importance, yet it is evident that the first two, construction and settlement, once accomplished, are practically forever done, but the third, the use of the water, is of annual recurrence, and in the end will determine the success or failure of the project.

This third stage, the use of water, has been given least systematic attention; but with the increasing population under irrigation, it is insistently clamoring for attention. In the arid and semi-arid region, irrigation, under present methods of use, can probably never reclaim more than one-tenth to one-fifth of the total area of tillable land. For our 14,000,000 acres of irrigated land there are at least 500,000,000 acres that must be reclaimed, if reclaimed at all, by other methods. There will always be more land than water in the arid region; and one of the chief concerns of every project should be to cover profitably the largest possible area. The actuating spirit of irrigation enterprise is, or should be, to make possible happy homes for the many.

With this thought in mind let me call your attention to two vital principles of irrigation success. First, the beginning of irrigation wisdom is the conservation of the natural precipitation, i.e., the rain and the snow. Irrigation is not a primary art; it should always be supplementary to the natural precipitation, and should only make up for the deficiency in the rainfall. The progress of dry-farming during the last decade has brought this truth home to the irrigated section. The water which falls from the heavens, even under an annual precipitation of ten inches, is amply sufficient to produce crops, could it only be fully held in the soil. By properly conserving the rain and snow-water in the soil by dry-farming methods, large crops may be grown with small quantities of irrigation water. This is well brought out in a series of experiments conducted during the last ten years at the Utah Experiment Station.

Table No. 1—The Crop-producing Power of the Natural Precipitation.

Yields per acre.	Inches of irrigation water used. None.	5.0 to 7.5.	Per cent. of yield due to rainfall.
Wheat (bush. of grain)....	39	47	84%
Oats (bush. of grain).....	55	64	86%
Corn (bush. of grain).....	44	54	81%
Wheat (pounds of straw)..	3,934	4,526	86%
Oats (pounds of straw)...	2,233	2,274	98%
Corn (pounds of stover)...	3,228	3,888	83%
Alfalfa (tons of hay)......	5,540	7,178	77%
Potatoes (bushels)	97	145	67%

The data in the above table show that approximately 85 per cent. of the yields, under irrigation conditions, of wheat, oats and barley, 77 per cent. of the yield of alfalfa and 67 per cent. of the yield of potatoes, was due to the natural precipitation stored in the soil. This is only a fair sample of what may be done on any irrigated farm if careful soil tillage be practised. If, now, by careful tillage the natural water had been allowed to escape into the air, much more irrigation water would have been required to produce the crops. By the proper storage of the rain and snowfall in the soil, alone, it is possible to extend our irrigated 14,000,000 acres considerably. Therefore, to make our irrigation projects of greater service, the settlers upon them must be taught that irrigation is designed only to supplement the natural precipitation.

Second, the yield of any crop under irrigation is not in proportion to the quantity of water applied. The more water is used in irrigating a crop, the less yield is obtained per unit of water. This has been amply demonstrated also in the long continued investigations at the Utah Station, already referred to. As examples, note the following results obtained with wheat and sugar beets:—

Table No. 2—Inches of Irrigation Water Applied.

	5	10	15	20	30	50
Wheat (bush. grain per acre)............	38	44	46	47	49	49
Wheat (lbs. straw per acre)...............	2,986	3,452	3,954	4,311	4,755	5,332
Sugar beets (tons per acre)...............	14	19	20	21	21	24
Wheat (bush. grain per acre-inch)......	7.56	4.35	3.05	1.86	1.39	0.99
Wheat (lbs. straw per acre-inch).........	597	345	264	172	136	107
Sugar beets (tons per acre-inch)..........	2.76	1.86	1.30	1.06	0.69	0.49

As the water increases, the yield becomes relatively smaller, and if enough water is applied, there is an actual diminution of yield. The studies of the United States Irrigation Investigations under Drs. Mead and Fortier have shown that excessively large quantities of irrigation water are used in ordinary practice. The losses which the irrigated

* Abstract of address before the twentieth National Irrigation Congress, Salt Lake City, Utah.

section has thereby sustained will probably never be known, but unquestionably run annually into millions of dollars.

It is of higher importance than ever before that a reasonable duty of water be established, and that those responsible for irrigation projects, by the education of the farmers as well as by the enforcement of reasonable rules, see to it that such duty is observed. At present, the duty of water assigned by the State Engineers is seldom as low as 30 acre-inches; usually, much higher. It will be a living question, in view of what we are learning concerning the relation between water and crops, whether even 30 acre-inches shall be allowed for one acre of land when it might be made to accomplish so much more if spread over a larger area.

Spreading 30 acre-inches of water over four instead of one acre, the increase in yield for wheat, corn, sugar beets and potatoes was threefold; for alfalfa even more, and for timothy twofold. Increasing foodstuffs in this manner, two and threefold, simply means that from two to three times as many human beings may be maintained upon the irrigated area; and every lover of the West dreams of the day when populous commonwealths shall cover the "Great American Desert." Irrigation is for the many, not for the few.

Table No. 3.—The Crop-producing Power of 30 Acre-inches When Applied to Different Areas of Land

Crop.	Thirty acre-inches spread over. 1 acre.	2 acres.	3 acres.	4 acres.
Wheat (bush. of grain) . .	48	91	132	166
Corn (bush. of grain) . . .	97	188	260	317
Wheat (pounds of straw)	4,533	7,008	10,356	13,204
Corn (pounds of stover) .	10,390	16,558	18,021	28,756
Timothy (pounds of hay)	6,054	7,688	11,739	11,928
Alfalfa (pounds of hay) . .	8,840	15,003	20,653	. . . .
Sugar beets (tons)	21	30	50	65
Potatoes (bushels)	105	373	456	544

By a more intelligent use of the waters already impounded or diverted the irrigated area may be increased largely, perhaps doubled. It is certainly a subject worthy of consideration. True, under the new projects, not yet well settled, there is no scarcity of water; yet in developing the West by irrigation should not the growth be symmetrical? We hope that no completed project will long remain without settlers; should we not be equally anxious that every new settler, from the beginning, use water the right way? In our older sections, water already is scarce; methods for increasing the duty are sought after; in time the newer sections will be in the same condition. Let us learn good habits in our youth, so that we shall have less to unlearn in our maturity.

FORESTERS IN DEMAND.

We note in the Conservation Publication for February an article which we publish herewith. It should be of importance to all those choosing future work and occupation.

The remarkable expansion of forestry work in Canada during the past year is evidenced by the fact that all the men who will finish forestry courses next spring at the University of Toronto were offered employment months in advance of their graduation. If the class were several times as large there would still be no difficulty in finding employment in Canada. The organization of the new Forests' Branch in the Department of Lands of British Columbia and the natural growth of work in the Dominion Forestry Branch, Department of the Interior, are largely responsible for this situation. At the present time the supply of Canadian foresters is far below the demand and this condition will continue for several years at least.

SOME FEATURES OF MACADAM CONSTRUCTION.*

By T. R. Agg.†

Inasmuch as water bound macadam has been written about and discussed so frequently, it would seem that there would be little need to consider it at a time like this. Nevertheless, it is not uncommon to see water bound roads under construction where little attempt is being made to observe the simple and well-known principles of such construction, and that is perhaps sufficient reason for some discussion of those principles at this time.

The well-known characteristics of a properly constructed water bound macadam road are: A well-drained, carefully shaped and thoroughly compacted subgrade; properly shaped side roads and ditches to insure the removal of surface water, and a layer of thoroughly compacted, properly bonded crushed stone, the surface of which has been well keyed together by rolling so that it presents a compact mass of stone of sufficient size to bear the loads that will pass over it without crushing and in which the stones are mechanically locked together by rolling and held in place by means of the dust from the crushed stone which has been worked into the interstices between the stones by means of water and rolling.

In deciding upon the size of the pieces of stone to be used for the upper layer of the water bound macadam road, two things must be taken into consideration—the quality of the stone which is available for use, and the amount of traffic and the weight and character of the loads which will pass over that surface. A road surface carrying a medium or light traffic, of which a small percentage consists of motor-driven vehicles, can obviously be made of smaller sized pieces of stone than a road surface carrying traffic made up of a great many heavily loaded horse-drawn vehicles, together with a large number of motor vehicles.

If the pieces of stone in the surface of the road are so small that the wheels passing over them crush them, it is inevitable that rapid wear will result and that the road will deteriorate quickly. On the other hand, if the surface of the road is made of very large pieces of stone, the traffic will not crush them, nor even wear them with sufficient rapidity to supply fine material to fill the interstices between the stones and keep the voids filled, notwithstanding the action of the elements and traffic. In such a case, the road will become rough and uneven, the surface being made up of rounded stones, which project slightly and make it disagreeable to traffic.

If the road carries any considerable proportion of motor vehicles, the water bound macadam does not prove satisfactory, but a surface made up of fairly large pieces of stone will withstand the action of motor traffic better than one made up of small stones, though the former is less desirable from the standpoint of the user on account of its roughness.

Somewhere between these two extremes, lies the ideal size of stone to use, which is a size sufficiently large to sustain the loads that pass over the road, without breaking, but small enough so that the wear on the surface will furnish sufficient fine material to keep the voids between the stones filled with dust and chips, thereby maintaining a smooth surface.

In the work of the Illinois Highway Commission, it has been found that with the soft limestone available, the size ranging from 2½ ins. to ¾ in., is most satisfactory. When stone of such a size is used it is, of course, desirable to have

* From a paper read before ninth annual convention of American Road Builders' Association, held at Cincinnati, December, 1912.

† Road Engineer, Illinois State Highway Commission.

the surface layer made up of fairly uniform pieces and to keep it free from pockets or patches of the finer material. This can be secured by harrowing the stone thoroughly, after it has been spread, by means of a heavy, stiff-toothed harrow. The harrowing not only brings the larger pieces of stone to the surface, but shakes down any pockets or patches of finer material that may occur.

The stone which is to be used for the wearing course in a water bound macadam, is, as has been mentioned, thoroughly locked together by means of the roller so as to form a closely knit surface. These stones are held in place by means of the mechanical interlocking resulting from rolling and by means of the stone dust and chips which are worked in between the larger pieces of stone by means of water and rolling. Eventually this finer material cements the stone together to form the wearing surface. A great many water bound macadam roads fail to give satisfaction because they were insufficiently rolled, and data collected in the construction of about 125 miles of 8-in. water bound macadam road in Illinois show that on limestone macadam there should be 0.04 of an hour of rolling per sq. yd. of finished macadam.

Most of the rolling should be done before any screenings are spread. If screenings are spread before the stone has been thoroughly rolled, they only serve to separate the larger stones. The resulting surface is made up of individual stones set in pockets of screenings and is not as durable as one made of stones firmly locked together by rolling before any screenings are spread. Moreover, if the screenings are rolled dry much the same result will be obtained. The screenings should be washed into the voids in the layer of stone and be allowed to set before much rolling is done on them. After the stone layer has received about all the screenings that can be washed into it and these have set for a day or two, the surface should be finished by rolling and sprinkling.

The durability of the surface will be greatly enhanced if it is covered to a depth of about ¾ in. with a good bonding gravel. Such a gravel should range from ¾ in. down, and should obtain 75 per cent. of hard pebbles, the remainder being sandy loam. The hard pebbles will gradually work in between the stones of the surface and will add materially to the wearing properties. In addition, advantage will be taken of the tendency for colloidal silicates to form under such conditions, thereby effecting a better bond for the surface than could otherwise be obtained.

Development of the bituminous macadam road has been brought about because the wear of the water bound macadam results in a fine dust which is disagreeable alike to the occupants of vehicles using the road, and to those who live along it, and because roads are being used by an increasing number of motor cars which have the well-known effect of blowing away the dust from the road surface and leaving an insufficient amount to fill the interstices between the stone, thereby allowing the stone to become loosened from the surface. Moreover, the thrust of the tire wears the surface rapidly and dislodges any stone not securely bound into the surface.

Inasmuch as the construction of bituminous macadam roads has been brought about to overcome some of the deficiencies of the water bound macadam, it is fair to assume that in the construction of these bituminous macadam roads, all of the good features of the water bound macadam should be retained and these good features be supplemented by the treatment which gives the advantages of the bituminous surface.

The object to be attained in the use of the bituminous surface is to hold the finer material in between the larger stones in the surface of the road so as to prevent loosening of these surface stones and to furnish a coating on the top of the road metal so that the wear on the stones will be reduced to a minimum, thereby eliminating a large part of the dust nuisance. There is nothing in the problem of bituminous construction which would be an argument for a change in the size of the stone or in the general method followed in water bound macadam construction, provided that the results which are desired from the bituminous surfacing can be obtained without such changes. With these principles in mind, the Illinois Highway Commission has been constructing the bituminous macadam by following, with one or two exceptions, exactly the same methods that would be pursued in building a good water bound macadam road up to the point where the bituminous surface is added.

The foundation of the road is prepared as carefully and in exactly the same manner as for a water bound macadam. The crushed stone is placed on the roadbed in layers of a thickness which will permit it to be thoroughly compacted by means of the roller. Usually the roads have been made 8 ins. thick, 5 ins. of which is in the lower course of stone and 3 ins. in the upper course. It has long been the practice among some engineers to bond the lower course of a water bound macadam road, although the practice is not at all general. In the construction of bituminous macadam roads, however, the practice of bonding the lower course has been adopted. The upper course of stone is placed and rolled exactly as if it were the upper course of a water bound macadam, care being taken to key the stone together thoroughly by rolling so that the amount of voids in the surface will be reduced as low as possible and the stones will be well locked together.

If a road is being built of hard stone, such as trap rock or granite, the upper course might be built of smaller sized pieces than is the practice of the Illinois Highway Commission, which is to use the same size as for water bound macadam. But, in any case, it is not believed that bituminous macadam can be constructed by the penetration method successfully if the upper layer consists of pieces much less than those ranging in size from 1 in. to 1½ ins. If hard materials of this class are used, the screenings may be used in the bituminous construction also; the size ranging from ¾ in. to ½ in. being spread before the first spreading of bituminous compound, and the size ranging from ½ in. to ¼ in., free from dust, being used for the final dressing.

If the screenings obtained from the soft limestones are used in the bituminous construction, there will be so much dust present even after repeated screenings that the bituminous application will be seriously affected on account of the presence of dust which will prevent the adhesion and penetration of the binder. Moreover, the small particles of limestone possess such a small wearing value that they are practically worthless in building up a durable surface. For that reason, it is better practice to use two sizes of screened gravel in the bituminous construction, one size commonly known as binder gravel ranging from ¾ in. to ⅜ in., washed and carefully screened, and a size known as torpedo gravel, ranging from ⅜ in. to ¼ in., also carefully washed and screened. The gravel used consists of smooth, round or angular particles, very hard and clean.

After the stone for the upper course of the macadam has been rolled, the surface voids are partially filled with the binder gravel, which is whipped into the surface from shovels, and the entire roadway broomed carefully to work the gravel into the voids and remove the excess from the surface of the stone. The surface of the macadam is then treated with an application of about 1 gal. per sq. yd. of bituminous compound, the binder being spread upon the surface of the road with a special pressure spray apparatus designed by the Commission. This apparatus consists of a furnace tank wagon capable of withstanding an internal

pressure of 100 lbs. per sq. in., equipped with a manhole for filling and a pipe at the rear for discharging. By means of air pressure on the tank the binder is forced out through a metal hose to an "L" shaped pipe nozzle arranged to discharge directly down onto the road surface. The nozzle is equipped with a steam jet which discharges through the orifice through which the bitumen flows. As a result, the binder is blown out in a fine spray and strikes the road surface with considerable force.

Great importance is placed upon the necessity for applying the binder under pressure so as to insure its being forced down into the voids in the surface of the road. At the same time, the spray blows away all dust or other fine material which would prevent adhesion to the stone. After the surface is covered with the binder, the macadam is rolled once over, with the roller wheels wet to prevent sticking. This rolling is simply to replace any stone that may have been disturbed in the course of applying the binder, and, after rolling, the surface is smooth and even for the subsequent treatment. After this rolling, the surface is sprinkled with the ¾-in. to ½-in. gravel, a small quantity only being used and the gravel being worked into the interstices between the stones with brushes, but a slight excess being used so that the pieces will project slightly above the level of the limestone of which the surface is composed.

This second spreading of gravel is again covered with a bituminous compound at the rate of about ½ to ¾ gal. per sq. yd. of surface, and after it is spread, the surface is immediately covered lightly with the torpedo gravel and rolled. The surface is then gone over with the third spreading of the bituminous binder, the quantity used depending upon the condition of the surface and varying considerably with the size and general quality and characteristics of the gravel used, but ordinarily amounting to from ¼ to ½ gal. per sq. yd. of surface. The surface is finally covered with torpedo gravel, rolled and opened to traffic. In the construction of roads in this way a layer of ¼ to ⅜ in. in thickness can be built up on the surface of the stone, this layer consisting of bituminous binder and hard pebbles, making a wearing surface which is of a mastic nature, and contains stone sufficiently hard to withstand a considerable amount of wear.

The action of traffic on such a road is to wedge down the gravel pebbles in between the limestone, forming a crust which is very hard and durable, and at the same time is smooth and affords an excellent foothold for horse-drawn vehicles and a very satisfactory surface for the use of automobile traffic. Usually the most satisfactory texture has been obtained in the surface of the road when the bituminous compound used is of such a nature that it "bleeds" or exudes during hot weather. A road built with such a compound works up into an excellent surface, but some attention must be given to it after the road is opened for traffic, as the "bleeding" will continue for two or three weeks or longer if the weather is hot. This "bleeding," however, causes no inconvenience if the road is kept under observation and covered lightly with gravel from time to time as is necessary.

It is essential in bituminous construction to have access to a laboratory equipped for the examination of bituminous materials if results are to be duplicated, and all materials used should be tested and the results recorded for guidance in future work. Moreover, the construction of bituminous roads requires supervision and workmanship of a high order.

There are many miles of road in the middle western states where of necessity water bound macadam must be built if the roads are to be improved at all in the near future, and there are also many roads that could well be improved with the bituminous macadam and thereby answer all requirements of traffic for many years. Either kind of road must be built with a due regard to a few simple but fundamental and oft-repeated principles which experience has taught are essential to success.

The following discussion then took place on the paper:

President Lewis.—I am glad, gentlemen, to have the author of this paper confirm what I have ventured to intimate in speaking to you at the opening session—that the day of the water bound macadam has not yet passed by any means. I congratulate you upon having had this subject so clearly and effectively presented.

R. A. Meeker (State Highway Engineer of New Jersey).—Mr. President and Gentlemen of the Convention,—I heartily agree with what Mr. Agg so truthfully said in his able paper—that little attempt is being made to observe the simple and well-known principles of macadam construction. While this to a certain extent is true there has arisen a demand for hard roads, and this demand in many cases has been so loud and long that every other quality requisite for a good road has been lost sight of.

It is true that macadam roads are dusty if neglected, but if properly maintained they are no more dusty than many other classes of pavement. Mark what I say—if properly maintained. The great trouble with the majority of road builders and the public at large is that they consider that if a road is once improved, that is the end of it, nothing more is necessary to be done, the road will take care of itself for all time. But the stone wears off, the fine screenings are ground into dust, and the impalpable dust is blown over into the neighboring fields. That is one ground of complaint in New Jersey that possibly is not troubling you people in the middle west. There are farmers and truck raisers who say that this dust depreciates the value of their crops, and particularly that of the smaller fruits. This to them is a serious matter.

If a water bound macadam road is well and properly taken care of and if material that is worn out by traffic is replaced with fresh material and not with dirt, your macadam road will not be objectionably dusty. Many and many a time have we seen a good macadam road covered with mud from the gutters. Of course, our gorge rises to a certain extent; and we get quite an unenviable reputation for kicking; and when they carry that abomination still further and deposit sods and grass upon a stone road words cannot express our feeling. A macadam road in perfect condition should contain not more than 21 per cent. of voids. This is not a guess; it is the result of a number of tests made of the material taken from many macadam roads that have been dug up and carefully analyzed. This density is almost impossible to obtain until after the road has passed through the first winter and spring. Then, if after the frost is out of the ground, the road is well and thoroughly rolled, and all the weak places that develop are strengthened, and the whole surface brought to a regular, uniform grade, the road will wear uniformly and form the best foundation for a future bituminous surface if the growth of traffic warrants the extra cost. This has been proven by years of experience. I would ask you gentlemen who have seen many macadam roads constructed—how many of them have you seen taken care of in the manner I have described? People seem to forget that the most critical period in the life of a stone road is, like that of a human being, during the first year of its life; and if the road is properly started and gets its proper consolidation the first year, it will last and wear until it is practically worn out. The ruts and dust and raveling of which we hear so much will not appear. Seventy per cent. of the roads in our country are off the through lines of travel. These can still be improved with crushed stone or gravel. If the increased travel causes dust to rise in such quantities that it

is objectionable, one or two light applications of a true bitumen will lay it. Possibly I might define a true bitumen as one which contains no lubricating material. If an alleged bitumen contains lubricating material the condition of your road will be like that of the man in scripture out of whom the seven devils were cast.

Mr. Agg's practice of harrowing the stones to secure uniformity in size, while effective for soft limestone, would never do for our harder trap rock and dolomite. We fully agree with his statement that it is necessary to have the surface always made up of fairly uniform pieces and to keep it free from patches of finer material. We find the only way in which we can secure uniform surfaces is by grading the stone carefully before, not after, it is spread upon the subgrade. This method of harrowing is from an economic standpoint, in some sections, a very good thing. But our experience has taught us that it is almost impossible to properly grade the stone after it is placed upon the road. Therefore we insist that our quarrymen shall supply us stone in regularly graded sizes, and if the stone does not come in those properly graded sizes we refuse to accept it. All of our specifications in the State of New Jersey are drawn in that way. Thus, the contractor who signs the contract to build a road under our specifications makes a contract with the quarryman that he shall furnish him with specification stone. That contract is binding upon the quarryman as well as upon the contractor, and if he does not receive properly sized stone he simply refuses to accept them, and the quarryman does not get any money. Just as soon as a quarryman finds that he is working for love he sees a light and makes up his mind to the fact that it is better to do as he agreed to and not as he wishes to.

All that Mr. Agg said about the necessity of thorough wetting and rolling we most heartily indorse. It is impossible to build a good macadam road without the use of plenty of water. In finishing a macadam road we have found no better rule than that of the master road builder, Edward P. North, who said: "Wet your stone until a wave of mud forms in front of your roller." Miles of macadam road in Central Park for years tested the truth of this maxim. What Mr. Agg said about the wastefulness of rolling screenings dry we indorse. It is a point upon which we are very insistent; in fact, so insistent that our specifications expressly prescribe that no screenings shall be rolled dry. A macadam road, whether it is built of limestone, dolomite, trap rock, or granite, must be treated as concrete and to get good results with your concrete you must puddle it thoroughly. To get good results from a crushed stone road the surface must be thoroughly puddled until the water comes to the surface. In the earlier days of our practice we were severely criticized for putting too much water on the roads and making the roads and shoulders muddy. Afterwards when the road was finished nothing was said about it.

I notice a great many practical road builders here, and they will all agree with me that if you do a good job you hear nothing about it, but if you make one slip, what you hear is aplenty.

We have listened to many able papers upon the more expensive types of pavement. It has been our endeavor to avoid mention of these as far as possible, confining our remarks to those road coverings that can be most cheaply laid. Each section of the country has material at hand which may be used with great benefit upon its highways. Commissioner MacDonald puts a light coat of stone chips upon his gravel roads and obtains a very good road. We have also used this method with very satisfactory results. If the road builder in each section of the country carefully tests the materials he has at hand, he will find something that if properly applied will greatly improve the surface of his roads—crushed stone in a rocky region, gravel in another, and a mixture of sand and clay in another, till at last we reach the alluvial flats where the paving is done with burnt clay as demonstrated by the Office of Public Roads, and what was alleged to be impossible in road improvement is accomplished.

In New Jersey we have a greater variety of soils and rocks than have many of the other states. Commencing with the older rocks of the northern portion of the state, we run down the scale until we reach the sand and alluvial plains near our southern limits. Therefore, our experience is possibly more varied than that of many others. We found that the old assertion that trap rock is the best stone which can be used for a macadam road is subject to qualifications. On heavily travelled roads trap rock is the ideal stone for water bound macadam. In roads of medium or lighter traffic, we find that a dolomite, or one of the harder limestones gives far more satisfactory results, is less costly to prepare, and at the same time forms a harder and smoother surface. Hence we must not take the maxims laid down in the books without a grain of salt. You will find possibly, in your own section, material that will improve your highways to a wonderful degree. Proper location, proper grading, proper drainage, and proper construction, will always yield very good results.

We hear a great deal about the waste of money spent in improving roads. It is said: "What is the use, why should we issue bonds for the roads when they wear out in ten years and that which has cost so much will all be gone?" In our state we have built some roads that have cost us $50,000 a mile, but over $40,000 of that was for relocation and grading. Now, that did not wear out. That was not dissipated, but is a valuable asset. When you consider that a 10 per cent. grade requires the expenditure of as much power to traverse one mile of it as would be expended in travelling 6.3 miles on a level, you begin to realize the advantages to be derived from reducing the grades. In the old days they told us that it was a waste of money to grade, and on the old road surfaces this was to a certain extent true, because any load that you could haul through the muck and mud of the flat you could haul up the hard stone hills. Now, those conditions are changed. Upon a uniformly smooth surface it is possible for a team to haul from four to six times as much on the level as it could possibly haul up the same old hills; and if we are to derive the full value from our improved roads proper grading must be given the attention which is its due.

President Lewis.—Gentlemen, this subject is open for discussion from the floor. We will be glad to hear from anyone, and I know that the author of this paper will be glad to answer questions.

F. F. Rogers (Deputy State Highway Commissioner of Michigan).—I would like to ask Mr. Agg about how much he has found the increased cost of bituminous over the plain water bound macadam, also what kind of materials he used this year, and if they have proven satisfactory?

Mr. Agg.—I will answer your first question and say that the difference in cost between the water bound macadam and bituminous macadam in the Illinois work has been about 18 cents. per sq. yd. Now, as to the repairs, the commission has been conducting experiments on sections of roads throughout the state upon which they have been using some of practically every bituminous material which is on the market in Illinois; and it would be impossible to go into the results of all those experiments this afternoon. The commission will shortly publish a report in which will be given the results of three years of experimentation with bituminous

compounds which have been used with about 20 or 30 different materials. If any of you would care to get that report and will write to the Illinois Highway Commission, Springfield, Illinois, I will be glad to see that you get a copy. In general I would say, however, that we have found that on the roads which are subject to a covering of sticky mud, pulling in from the side roads, which is a condition that is found in most of our roads, we found the various kinds of tar binders to be unsatisfactory. On the other hand, we have used on some roads which are not subjected to this action, tar binders which have given excellent results. We have also found binders which could be used on a road in a soil of an acid nature, the kind of soil we have in southern Illinois, and the same binder used on roads in the northern part of the state where the soil is alkaline or neutral, went to pieces very shortly. As I have said, we have an extensive series of experiments going through our laboratory, the results of which will be given later.

Mr. Rogers.—Just one other question as to the comparative results of hand pouring and pressure spraying?

Mr. Agg.—We used the hand pouring method for two years and then followed that by two years of the pressure method. It seems apparent to us that you cannot hope for satisfactory results in bituminous work by the hand pouring method. Occasionally a good road is constructed in that manner, but, in general, in our work we have found that about one road out of four constructed by the hand pouring method has proved satisfactory. This is due to the fact that inevitably the bituminous binder will be thicker in some places than it will be in others. When the road is put under traffic, this condition is not apparent, but as the road gradually wears, the traffic gradually compacts the surface, then the places where the binder is thick are seen as raised places in the road. The places between these high places being lower, the action of traffic is to increase this effect as time goes on. Some roads that were constructed by the hand pouring method three years ago had to be entirely resurfaced because the surface became irregular. The texture was all that could have been asked, but it was in this condition due to the effect of the binder put on in that way. We do not think that bituminous macadam can be put down by the hand pouring method. (Applause.)

John S. Gillespie (Road Commissioner, Allegheny County (Penn.) Road Department).—Mr. Chairman and Gentlemen: I am taking issue with Mr. Agg and our distinguished chairman in regard to the macadam road. It is something like a prescription. A prescription may cure one when it will not cure another. Macadam roads may be successful in some places, and not in others.

I have charge of the roads of Allegheny County, Penn., and some of you gentlemen have pamphlets showing what Allegheny County has done for good roads. We have at the present time in our county, 450 miles of improved roads. A year ago we had 360 miles of macadam, yet at the present time we have only 308. The reason for this is, up until September, we had about 60 miles of macadam road and we made the same into asphalt roads. Macadam roads are not a success, and have never been since the automobile came into existence. It may not make a difference in the East where Mr. Meeker is—I have been over a great many of his roads—they have the hard trap rock. We, in Allegheny County have the limestone, and most of that is shipped in from Ohio.

I am going to give you the specifications of our roads; and I don't think there is a macadam road built anywhere in the United States that is better built than we are building. Our macadam roads are built with 8 ins. of telford stone, thoroughly rolled and napped, and then we have the macadam top of 4 ins., giving us a 12-in. road. And yet they are not successful.

In regard to the dust, the limestone dust; we have that. We take care of that problem. I am not the father of good roads in Allegheny County, but I have been the mother of good roads for seven years; I have been taking care of them. We do all our own repair work. We have 14 road rollers and we have 14 gangs that are going all the time. Two years ago this summer I had charge of putting on 96,000 tons of stone in resurfacing our roads. We spend $1,500,000 a year on roads. You will notice by the pamphlet our valuation is high, the same amounting to $1,141,567,110, and there isn't much trouble for us to get money. We have plenty, and we can try anything that we want to that looks good. We have used oil. Five years ago this summer I came down to Cincinnati in company with our county commissioners. We went to Lexington and looked over their oiled roads. Last year we used 422,000 gals. of oil. We have not used less than 300,000 gals. of oil per year for the last five years. Now, I just tell you that to show you that we care for our roads. Not only that, but we have a patrol system in Allegheny County. We always have had it, ever since the first road was built. At the present time we have 110 caretakers. Each caretaker has between 3 and 4 miles of road to take care of. These men are hired by the year; they work every day, and are paid $55 a month. Their duty is to go along and keep the ditches and sewers open, and keep the weeds cut down. As you all know, weeds grow rapidly along a macadam road, especially a limestone road, because limestone is a great fertilizer.

Our experience is that macadam roads are no good. They are a good substitute. As Mr. Agg says, you have to fall back on the macadam. That is all right, but if you if you have the money you don't want to fall back on macadam. Now, some of you gentlemen have been to Allegheny County and seen our roads, and know that we have built them right, yet they do not stand.

In regard to putting down the macadam road, from practical experience this is what I found: The contractors do not build the roads, or put down macadam roads as we do, because it takes a little more time. I am going to tell you now how we bond our roads so that you will know whether or not we do it right. In putting our roads down we do much the same as the gentleman from Illinois; we put our stone down and thoroughly compact that. I found from experience that by using the larger stones we got the best results. You can go along a road and reach down, blindfolded, and pick up all the stone you can hold in your hand; probably there will be three or four pieces, and by pressing them together they will interlock, and that is why the larger stone is used. That is how the Romans built their roads, with the larger stones and of a uniform size. We roll that thoroughly, and I have taken 60 bushels of coal across the road just after the rolling and before any screenings were applied, and hardly made any impression on it. We roll the ballast well, and then we put on a slight sprinkling of screenings, and by the roller passing over the same two or three times it shakes the screenings down between the stone. Then we apply the water, thereby getting the road to bond from the bottom. We put on only a light coat of screenings, "feeding" it, as I say to the men, in order to get the proper bond. We then roll the same until we have a batter all over the road. We leave this then, and take the roller on to a new piece of 40 or 50 ft. Too much screenings has a tendency to "choke," giving you the necessary batter, but not the bond.

I might say that I have always found in putting down a macadam road that it is best not to take too long a stretch,

because one of the most important points in building a road is the water. If your roller covers too great a distance, you do not get all the benefit of same as by the time the roller goes over the road a second time, the water has soaked into the foundation. I find you have to seesaw quickly to get the advantage of same. You must get the benefit of it before it enters the road.

In starting the new piece, the same methods are applied which I have just given. In a day or two the sun bleaches the road, causing white spots to appear. We then take the roller back and roll the same thoroughly. We then take the roller off and flush the macadam surface well with water, and we leave it. That flushing cements the road tight, and the result is, in a day or two we have a road with a hard, metallic ring. Now, that is the way we put our macadam roads down, so you can be the judges as to whether or not we put the same down right. I condemn it. A macadam road in certain seasons of the year, or certain winters, is better than others. In Allegheny County three years ago this winter, the independent ice companies did not get a single pound of ice. It would freeze a little at night, and thaw out in the morning.

Seven years ago, when I took charge of the roads in Allegheny County, I was conceited enough to think I knew a little about roads. Things I advocated then, I condemn now. Then the macadam road was good, but we have a different traffic to-day. The automobile has come in and it has come to stay. Even those who say macadam roads are good, find fault and say they can't take care of the automobile.

As I was going to say, where you have an open winter, the frost goes into the macadam, and in leaving the same in the spring it disturbs the bond, making the road "green." During this period you can watch a heavily loaded wagon go along and rut your road. Now, if you could only close your road in the spring when the frost is coming out, could close it entirely to traffic, the elements would rebond it, but we can't close them and the roads get rutted. Now, gentlemen, that is my experience and my belief is that the macadam road is no good. I don't say they are no good everywhere, but they are no good in our county, nor in the western part of Pennsylvania. We can't get trap rock. A gentleman here at this convention told me that he could sell us trap rock, f.o.b. the boats at Cleveland for $1.50 to $1.60 per ton. Now, if we are to pay that price at Cleveland, together with the freight to the Pittsburg district, making a total of $2.25 to $2.50 per ton, it will be cheaper for us to adopt the mechanical mix or penetration. That is what we are doing. This summer we put down 17 miles of penetration and about 30 miles of the mechanical mix.

We have all kinds of roads in Allegheny County, we have the macadam road, brick road, rock asphalt, Warrenite and Amiesite, and we have all kinds of resurfacing work. The telford foundation of the first road constructed in our county is still there, we never lose the foundation and the second time a road is covered it is better than the first, even with macadam.

Will P. Blair (Secretary, National Paving Brick Manufacturers' Association).—There is just one suggestion that I want to make. It may not reach the point, but the last speaker has just stated that the greatest trouble they have with their macadam roads in Allegheny County is the fact that in the spring of the year and during light winters, where they are having constant freezing and thawing, the road gets into such a condition that it is easily rutted. Now, if the gentleman will permit what may seem to be a criticism of the way in which they build their roads, and leave their roads in that county, it will be given in the best of spirit, and I believe it may be of some assistance to them, and to all road builders. The condition of a great many roads in Allegheny County is this: The water is not carried from underneath the bed of the road to the ditches on the side of the road. That is the condition of a good many macadam roads in this country in the winter and spring. And that is the trouble with all kinds of roads unless you carry off the water or the moisture and let the air in, not by building a ditch along the side of the road, not by conveying the water from certain stream watering places on the road, where the water oozes out under the road, etc., not by carrying that down the middle of the road and into the side ditches, but by putting in cross tiling at right angles, across the roadbed, and getting that moisture immediately out and keeping your roadbed dry. If you keep your roadbed dry underneath, your moisture, or your temperature—your low temperature—is not going to disturb the aggregates and the condition of the road as found in the summer time. Keep it dry, and it is going to keep in place. That is just a suggestion.

Mr. Gillespie.—Just a minute, please, in answer to Mr. Blair. Gentlemen, I said that the first road built is still as good as ever; and that was built in 1897, showing that it isn't the foundation. We put French drains in every 50 ft. during the construction of our roads. I say that when our roads are resurfaced they are better than when first built. It is not the foundation that gives way, it is the top coat that blows away, the telford remains. The matter of drainage is well taken care of by the frequent use of these French drains.

COMBINED STEEL OUTPUT.

The combined output of steel in the United Kingdom, Germany and the United States in 1911 exceeded 45 million tons, whilst the world's output is estimated at between 59 and 60 million tons. A comparison of the approximate outputs of the chief producing countries shows that the United States produced in 1911, 23,676,000 tons, Germany 14,778,000 tons and the United Kingdom 6,565,000 tons. A noteworthy feature of the returns is the increase of about 24 per cent. in Germany's steel output, whereas that of the United Kingdom and the United States remains practically stationary.

POWER PRODUCTION COSTS.*

Cheaper generation in the near future is dependent on more efficient turbine plant, and the recovery of by-products from coal by the employment of gas fuel for firing boilers. The companies whose business is general supply, as contrasted with the special purpose power stations, might be expected to take fuller advantage of such tendencies. But in any case the margin for saving in costs of production must be substantial. When it is observed that a municipal plant such as that installed at Stockport, consisting entirely of reciprocating engines, can gain merited approbation for working costs of 0.56d. per unit on a load factor of 23.42 per cent.—a result as favorable as that achieved by Manchester, generating nearly twenty times the quantity and employing large turbines—it is clear that there is a large field for profitable study in this department. By the improved load factor resulting from more general and diversified demand numerous items of expenditnre can be reduced in proportion to output while the coal costs may almost disappear when the full by-product value is realized.

CONTENTS OF THIS ISSUE.

The article on Storm Water Discharge, by R. O. Wynne-Roberts and T. Brockmann, will be concluded in next week's issue, March 13th.

FORESTRY AND IRRIGATION.

A great number of people do not realize to what extent the present efforts towards development of scientific and practical forestry will ultimately benefit irrigation. The extent to which it will simplify the work of engineers in the economic handling of water is often not understood. These benefits apply more particularly to our timbered provinces, but, in so far as most of the rivers of the prairie provinces have their sources in the forest lands, it applies to them, though not to the same extent, as well. British Columbia, however, on account of its topography and the great possibilities of irrigation in that country, ought to be more vitally interested than the other provinces in the proper understanding and practical working out of the relation of forestry to the making productive of its many large tracts of fertile land.

The aggregate of water power available in British Columbia is tremendous, and the province is only in its infancy as far as development and using that water for man's benefit goes. The greatest difficulty with northern mountainous countries re water courses is the variable flow of water. Summer's sun, even when there is no rain, produces such a melting of snow on the mountain tops, that the rivers are, many of them, in flood or high-water mark in August. In the same way, cold in winter reduces many streams to practically nil. This variation results in many a fine summer's waterfall being out of consideration, commercially, for power development purposes, but it is not so serious a drawback for irrigation purposes. Irrigation is only needed in the summer, and if a country can utilize its gushing summer streams for an increase of the productiveness of the land, the better are the people and the province. It is in the lessening of difficulties and expense for irrigation that forestry holds out promise to the people and engineers. Forests, as we all know, act as a protection to moist earth by keeping off the sun's rays. We have seen, for example, snow in our woods long after it has disappeared from the open places. The forests are partially a storage basin for the winter's moisture or for sudden rains. Strip British Columbia's hills of the forests and it would only aggravate the variable high and low water levels of its rivers, and there is a consequent increase in the costs when trying to properly control and distribute such water. Not only this, but the sun, after the forests are cleared and fires taken place, often bakes the surface hard, and rainfalls gathering on the surface rush down, scouring and gouging out earth in deep channels, and may possibly, by depositing unfertile mountain soil on lower productive lands, finally destroy the fertility of the good land itself. In short, clearing a mountain hillside bare of trees may just mean to the land below that, whereas formerly irrigation and fertile acres were possible, yet afterwards, thanks to the extra expense involved in controlling and suitably distributing the water under the new conditions, the whole plan becomes as a commercial proposition impossible.

This is not likely to happen often, but even if it does not make irrigation impossible, yet as a general rule one can state: "The more unconstant the feed of waters to lower levels due to mountains cleared of trees (either by lumbering or fire), the more increased the cost of handling that water for irrigation." Whether the irrigation is in the form of government work paid for by taxes or by rent to a water company, the people pay, and in the absolute destruction of forests the country is not only poorer by the loss of lumber, but indirectly by the added cost of land fertility.

British Columbia has not been asleep in its attention to its water rights and powers. Its Water Act of 1909 re irrigation was an improvement and an advance on all

the laws of this continent. California was trying, and has possibly passed by now, legislation modelled after certain provisions in the Water Act of British Columbia. Canadians can take pride in seeing the leading irrigated state in the United States willing to learn off a province in its infancy as regards irrigation. Let us hope British Columbia meets with a fitting reward in the way of good results and prosperous people.

TWO GOVERNMENT INVESTIGATIONS

The United Shoe Machinery Company has had the doubtful pleasure of being investigated as an alleged combine by the governments both of Canada and of the United States. While nominally the companies are distinct, in reality the Canadian concern is a subsidiary of the Boston firm.

The matter received additional interest in view of the recent decision of the Supreme Court at Washington, which held, in effect, according to a despatch from that city, that the Sherman anti-trust law does not forbid the mere combining of non-competitors in an industry. The company was held to be a legal concern.

In Canada, two of the investigating boards concluded that the United Shoe Machinery Company of Canada was a combine. They reported on October 18th, 1912, their conclusions as follows:—

"Such advantages as are claimed by the company for its system of doing business, when they are not inconsistent with the existence of competition, are not vital to a consideration of whether competition is unduly restricted; neither are any complaints made by the manufacturers where the ground of these complaints would disappear if the way were open to competition.

"Eliminating from consideration all those elements of the relations between the company and its customers, we find that:—

"The United Shoe Machinery Company of Canada is a combine, and by the operation of the clauses of the leases, quoted in the foregoing, which restrict the use of the leased machines in the way therein set forth, competition in the manufacture, production, purchase, sale and supply of shoe machinery in Canada has been and is unduly restricted and prevented.

The representative of the company on the investigating board signed a minority report, stating that, while the facts established by the evidence submitted to the board were set out in the majority report, he differed with the other members of the board with the conclusions that were drawn from those facts. He thought that, considering the company's methods as a whole, they were not against public policy. The company, he added, had been of manifest advantage to the manufacturer of boots and shoes, to the labor operating the machines, and to the consumer.

Discussing the case against the United States company, District Attorney French, who had charge of the government case against the corporation, is reported as saying:—

"The question which has just been decided by the Supreme Court was merely one of criminal pleading. The great and important issue between the people of the United States and the United Shoe Machinery Company is whether or not the latter is a monopoly in violation of the Sherman act, and this depends largely, if not wholly, upon the view which the courts will ultimately take regarding the tying clauses in the leases, or, generally speaking, of the patent question involved. Upon these matters the court expressly declines to pass, apparently for the reason that they were not presented by the record, and says in effect that it must accept without question the interpretation of the lower court, which regarded the indictment as merely referring to the organization of the company, not to the 'tying clause' leases."

The strongest feature of the United States Government's effort to show an unlawful combination in restraint of trade, says Solicitor-General Bullitt for the Government, was the "tying" clause of the agreements, by which it is alleged that the company sought to compel shoe manufacturers to buy machines from it and none other. That question, he declared, was not considered by the court, because the lower court had interpreted the indictments involved in the latest decision as referring solely to the organization of the United Shoe Machinery Company.

The tying clauses were largely the bone of contention in the Canadian case. Mr. Winslow, president of the company, admitted in the Canadian investigation that the purpose of the tying clauses was to give the company that security by preventing the introduction of other machinery into the factory. He stated that if the company were obliged to remove the tying clauses from its leases a change in its system of doing business would be necessary. He was not able to state the basis on which the rates of royalty were calculated, these having been continued from the previous leases. He assigned no reason for the necessity of a change, nor did he indicate what that change would be.

No other evidence was adduced by the company to show what would be the nature of the changes to be made in its system if the tying clauses were eliminated, nor that changes would be necessary for the protection of its interests.

"As indicating that the object of the tying clauses," said the Canadian majority report, "is rather to prevent the introduction of competing machinery than to establish continuity of operation, it may be noted that the company's welter and stitcher will be leased to work in connection with other principal machines obtained from outside sources, that machines corresponding to the machines of the company's general department can be obtained from outside and introduced into the service, and that the company will sell the machines of the general department, in which event the company has not the same interest in keeping the machines in order as exists when machines are leased."

The Canadian investigators found the company to be a combine, and, as the six months' delay recommended and adopted, dates from October 18th, 1912, the company is liable to a penalty not exceeding $1,000 and costs for each day, after April 18th, 1913, during which the company continues to offend. The court procedure in Canada seems to have been far more simple than in the United States, where the government has not yet fired its final shot in the case.

EDITORIAL COMMENT.

We are pleased to be able to give in this week's issue a further summary of the discussion which took place at the recent annual meeting of the Canadian Society of Civil Engineers, held in Montreal, January 28th to 30th. It was impossible to cover this discussion fully in the limited amount of space at our disposal in the daily edition of *The Canadian Engineer*, which was issued in connection with that meeting. We are glad, however, that we have this opportunity of giving it now, and it will, no doubt, be read with a good deal of interest by not only the delegates who were in attendance at the convention, but by many other members of the society who were not able to be there.

THE MOOSE JAW WATER SUPPLY.

By P. Gillespie, B.A.Sc., A.M.Can.Soc.C.E.*

That portion of Alberta and Saskatchewan between the 54th parallel of latitude and the International Boundary comprises nearly 250,000 square miles. It is drained by the Saskatchewan and Assiniboine Rivers and contains not a single body of water as large even as Lake Simcoe. On a basis of only 20 persons to the square mile, this region would become the abode of five millions of people. The present population is something in excess of 800,000.

When we consider that the great centres of population in Europe—St. Petersburg, Christiania, London, Paris and Berlin—lie north of the 49th parallel of latitude, that the great migrations of history have been westward and northward, that Canada is the last great area awaiting the enterprise and energy of the pioneer, that while in point of population the United States of America stood 100 years ago where Canada stands to-day, her railway mileage was not until 1857 equal to that of the Canada of to-day, nor her foreign trade as great as that of this country at the present time until the year 1861, it will, I believe, be granted that the growth I anticipate is a very moderate one indeed, and that the problems consequent theron are really only beginning. One of these is that of water supply.

To the life-long resident of Ontario, with its fine series of inland and border streams and its magnificent chain of great lakes, this special problem of the western plains will scarcely appeal. In the prairie provinces, as indicated above, the scarcity of streams or lakes capable of serving large communities has rendered it both acute and unique.

The city of Moose Jaw, Sask., is situated on the main line of the Canadian Pacific Railway, some 420 miles west of Winnipeg, and 40 miles west of Regina, the provincial capital. In the language of the surveyor, it lies in Township 16, Range XXVI., West of the Third Meridian. Its present population is approximately 25,000, probably half of whom are dependent directly or indirectly upon railway operation and maintenance for a living. It is surrounded by an excellent agricultural district, and of late years has experienced a period of growth and prosperity which would be regarded as phenomenal in older districts. In consequence, it has outgrown many of its public services, including its water supply. Up to a few weeks ago this was obtained partly from a well in the city near the confluence of Thunder Creek and Moose Jaw Creek, which is fed by an infiltration gallery receiving water percolating from the creeks through the soil; and partly from Snowdy Springs, so-called, seven miles distant in a southwesterly direction, the supply flowing by gravity through a ten-inch wooden main. Two years ago a deep well was bored at a point adjacent to the present city power house in the hope of locating natural gas. On reaching a depth of some 1,200 feet the drilling was temporarily abandoned, a heavy flow of water having been encountered. This water is saline and by itself not potable. In cases of fire it was the custom to pump raw creek water and gas-well water into the distributing system, the subsequent draining of which by hand having been relied upon to free the mains from water unfit for domestic use. Of late years the supply has proved quite inadequate to the needs of the citizens, so much so, in fact, that at times water was available in the service pipes for an hour only three times a day.

In the spring of 1911 Mr. Walter J. Francis, C.E., of Montreal, was asked by the municipality of Moose Jaw to investigate the entire situation and advise as to a water supply from this western city. Mr. Francis began his investigation early in May. This involved a study of some ten suggested courses, most of which were found to be impossible because of one or more of three reasons, viz., insufficient quantity, unsatisfactory quality or prohibitive cost. Among the sources investigated were the Moose Jaw Creek, Last Mountain Lake, the Snowdy Springs, the South Saskatchewan River and Sandy Creek, all well-known to residents of Southern Saskatchewan. For the reasons indicated above, all were rejected for immediate development, save the last-mentioned—Sandy Creek—a stream near Caron, some 20 miles west of the city along the main line of the Canadian Pacific Railway.

Mr. Francis' report, in brief, suggested that the city proceed at once to concerve its then present supply by installing a separate high-pressure fire system in the business district. This would enable the city to cease using the limited domestic supply for such purposes as street watering, most manufacturing processes and fire-fighting. The city was also advised to proceed at once to make a thorough exploration of the valley of the Sandy Creek. The indications at the time the report was prepared were that there was available there one million gallons of water per day. If this, by subsequent investigation, should be confirmed, it would mean that this quantity, together with the supply at that time serving the city, would be sufficient for a city of 30,000 people. The ultimate source, it was obvious, must be the Saskatchewan River in event of the population very much exceeding the limit indicated. Moreover, if the Sandy Creek project were to be developed, much of the necessary installation would become a part of the Saskatchewan development, since both sources lie in the same direction from Moose Jaw. The expense involved in utilizing the Saskatchewan necessarily placed it beyond the immediate reach of any single municipality as far distant as Moose Jaw, but a suggestion was made that the city combine with other interests and prepare at once for the use of the Saskatchewan River water at a time not far in the future.

The city council of Moose Jaw, with characteristic western enterprise, immediately voted an appropriation for the investigation of Sandy Creek, which investigation was conducted during the summer months of 1911. Weirs were installed in eight different places on the creek, from which daily readings covering several months were obtained. A number of deep test wells were drilled in various places across the wide valley of the creek, revealing the presence of a lower supply of water (apparently separated from the upper by an impervious stratum of clay) whose analyses were markedly different from those of the surface water. The knowledge acquired during the exploration tended to confirm the earlier opinion as to quality and quantity, and Mr. Francis' firm, Walter J. Francis & Company, were authorized to proceed with the preparation of final plans and specifications and the supervision of the work. The contracts for the work were awarded during the early months of 1912 and construction was actually begun in April of that year. The water was in use in Moose Jaw before the end of November or within eight months.

The works consist of an infiltration or collecting gallery terminating in a main well over which is constructed a headworks pumping station, a pressure main, a headworks reservoir of 500,000 gallons capacity, a gravity main 96,200 feet long extending from Caron to Moose Jaw, a storage reservoir (in the city) of 2,000,000 gallons capacity, a second pumping station and an elevated tank.

The Infiltration Gallery.—The infiltration gallery will consist, when complete, of 4,000 lineal feet of 20-inch glazed tile, laid with semi-open joints in the water-bearing sand of the valley of Sandy Creek, at a depth of about 16 feet. Manholes are provided every 800 feet, or wherever changes in

---

direction occur. The invert of the pipe has a gradient of 0.4 per cent., and is approximately parallel with the natural surface of the ground in which it lies. The lower semi-circumference of each joint is sealed with a cotton sack filled with what was originally dry cement and sand. This is carefully placed in the invert of the bell when the pipe is laid. This sack adapts itself to the irregularities of the tile while still soft, and later on prevents the admission of sand to the pipe. The upper half of the joint is protected by a depth of one foot of graded gravel which, for the sake of economy, is confined in a cheaply constructed box of spruce lumber scribed to the curvature of the tile. This also prevents the entrance of sand into the interior of the pipe. It will be seen from this that the gallery is intended to drain the surface stream and that it may lower the level of the ground water down to, but not below, the axis of the pipe.

with was the prevention of water coming into the trench from underneath the piling, especially where the line led across lagoons, as it did in a portion of the work.

The infiltration gallery terminates at its lower extremity in a main well circular in plan, 15 feet in diameter and 29 feet deep, and constructed of concrete. An adjunct of this well is a valve chamber through which the water passes on its way to the well and admission to which from the gallery is controlled by a 16-inch gate valve operated from the floor above. This valve chamber is provided with a permanent metal weir enabling the operator at any time to determine the quantity of water being received from the gallery. The excavation for this well was done entirely by the dredging pump. Over the well stands the headworks pumping station.

Headworks Pumping Station.—The headworks pumping station is a brick structure, 48 x 36 feet in plan with concrete foundations, base, floor and roof. The mechanical equipment includes two Fairbanks-Morse two-

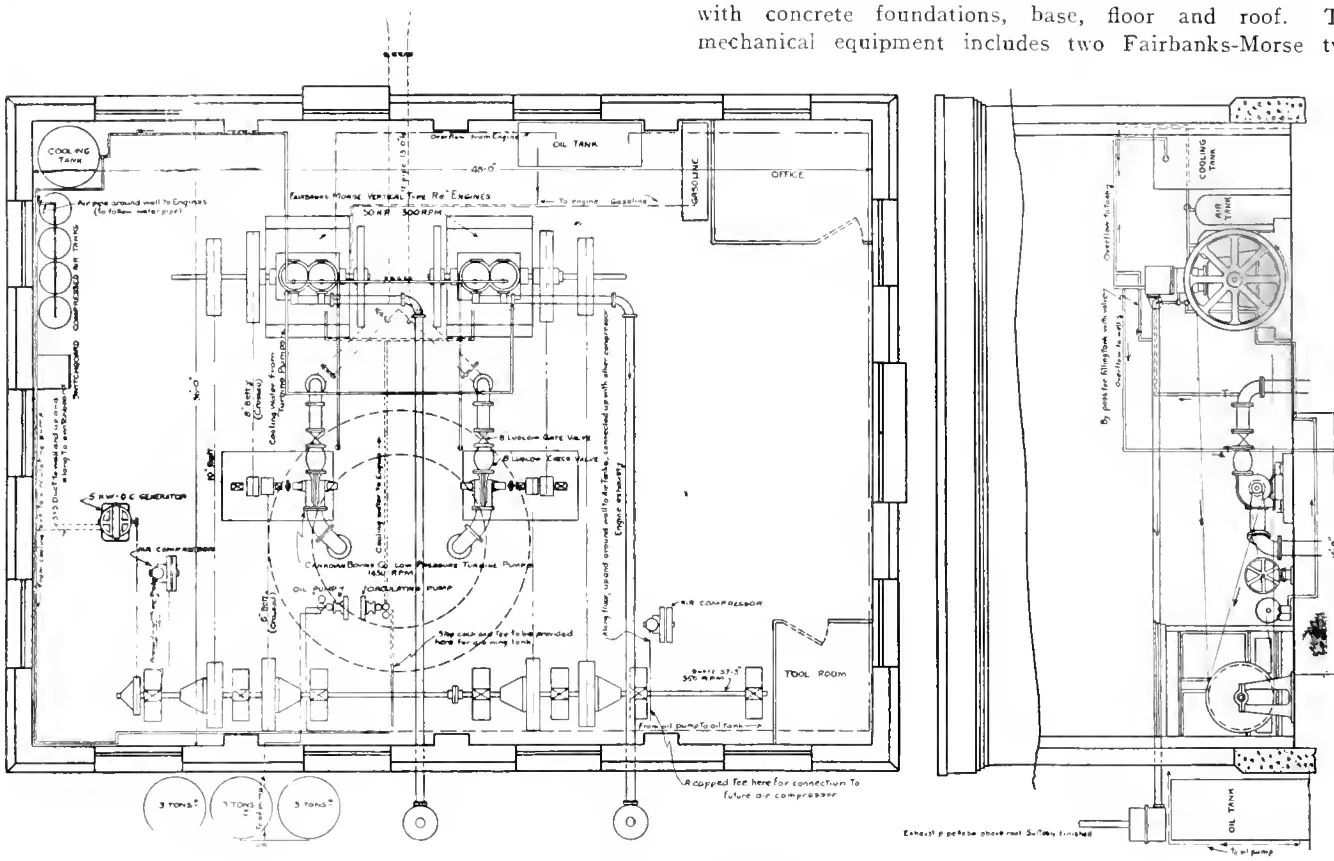

Fig. 1.—Headworks Pumping Station.

The laying of this gallery in a water-bearing gravel and quicksand presented some special difficulties. Two parallel rows of 9-inch United States Steel Company's interlocking steel sheet piling 18 feet long were driven one on either side of the proposed centre-line of the gallery and distant therefrom two feet. This was accomplished without special trouble with the aid of a 2¼-inch McKiernan-Terry pile hammer fitted with special driving cap, and by a liberal use of the water jet. The first six feet of depth of excavation was done by hand, after which a 6-inch Goulds centrifugal dredging pump was put into service and the remainder of the excavation done thereby, sufficient water to render this operation possible being meanwhile admitted to the pit from the creek above. Bulkheads and transverse shoring were placed as the work progressed. The pulling of the piles was accomplished by the aid of a Yale & Towne 3-ton triplex chain block for starting and an ordinary pair of triple blocks with a 1-inch fall and a steady team of horses for the rest of the operation. A generous application of axle grease to both bulb and channel sides of the pile during the driving greatly aided the pulling afterwards. The greatest difficulty met

cylinder, four-cycle, 50 h.p. vertical oil engines, belted through a line shaft to two Böving centrifugal pumps, each of 600 gallons per minute capacity. The arrangement is such that either or both pumps may be operated by either engine. The nominal speed of the engines is 300 r.p.m., and that of the pumps 1,450 r.p.m. The two discharge pipes join with the 18-inch pressure main in a special wye outside of and below the pumphouse wall. Each pump is protected by a check valve set in the discharge main and priming, when necessary, is done by a by-pass connecting the pressure main beyond this valve with the pump casing. In addition to the engines and pumps there is a 5 kw. generator for lighting purposes, an air compressor and air storage tanks for starting, and oil and water pumps for fuel and cooling respectively. Ultimately, when it is decided to install the deep wells for the purpose of obtaining the water in the low-lying strata of gravel, an air-lift equipment will be employed and the compressor capacity will be increased. Provision for such increase has been made in the lay-out of the station. The usual storage tanks for oil, gasoline and water are provided and complete the equipment.

The Pressure Main.—As stated elsewhere, the pressure main has a diameter of 18 inches. It consists of welded steel tubes of thickness ¼ inch and of average length 17 feet. The ends are plain and the joints are made by the Custer method. A sketch of this joint is shown herewith in Fig. 2. The joint mechanism consists of a collar sufficiently large in diameter to slip over the ends to be connected, two followers or gland rings, two rubber gaskets and ten track bolts. The collar is ten inches long and on its interior are two projecting buttons which insure half the collar covering each of the two ends to be connected. A special Custer wrench is used for tightening the bolts. The advantages of this joint are that it is slightly flexible after being laid, that it can be made under water, and that a change in direction equal to three degrees at each connection can be secured with 18-inch pipe. With 10-foot lengths it will be seen that a thirty-degree curve could be followed if necessary. Experience has shown that if proper care be taken in the jointing. Absolute watertightness can be secured. The specification for laying required that as soon as the pipe was connected up, backfilling to a depth of one foot over the pipe, carefully rammed, should be done. The objects of this were to avoid injury to the pipe in case of caving-in, and to prevent the pipe floating in wet situations where water could not enter the free or open ends of the pipe. Part of this pipe had to be laid at a depth of 14 feet and over, owing to the irregular nature of the ground through which it passed, and the advisability of avoiding summits in the profile of the pipe.

Headworks Reservoir.—The headworks reservoir is an all-concrete structure circular in plan, 75 feet in diameter and holding, when full, 17 feet of water. The roof, which is of the girderless type, is supported by 9 columns placed in three rows of three each. Admission of water to the reservoir and discharge therefrom are controlled by 18-inch gate valves. The admission valve is protected by an 18-inch check valve. The roof is about 8 feet above the normal level of the ground. Backfilling against the exterior walls and over the roof slab adequately protects against frost. The concrete was the equivalent of a 1:2:4 mixture thoroughly well mixed and carefully tamped. No other waterproofing precaution was employed and when, after construction, the the reservoir was tested full for 24 hours a leakage of less than ¼ of 1 per cent. occurred. The difference in level between the normal water level in this reservoir and that of the storage reservoir at Moose Jaw is 57 feet. The infiltration gallery, headworks pumping station, pressure main, and headworks reservoir were done by day labor instead of by contract, it having been felt that the many uncertainties to be anticipated rendered this procedure advisable.

The Gravity Main.—The gravity main from the headworks or Caron reservoir to the city is of 18-inch welded steel with Custer joints of the type already described. The invert is laid at an average depth of 9 feet. To facilitate examination and repairs, it is divided by gate valves into sections averaging one mile and two-thirds in length. The entire pipe is laid on either a rising or a falling gradient, the objects being to permit entrapped air to rise to the summits where air valves are provided. At each air valve there is provided also a poppet inlet valve for the purpose of admitting air whenever a section of the line is drained. Six-inch drains are provided at all depressions and are controlled by six-inch gate valves. These will permit the main to be unwatered in sections when necessary.

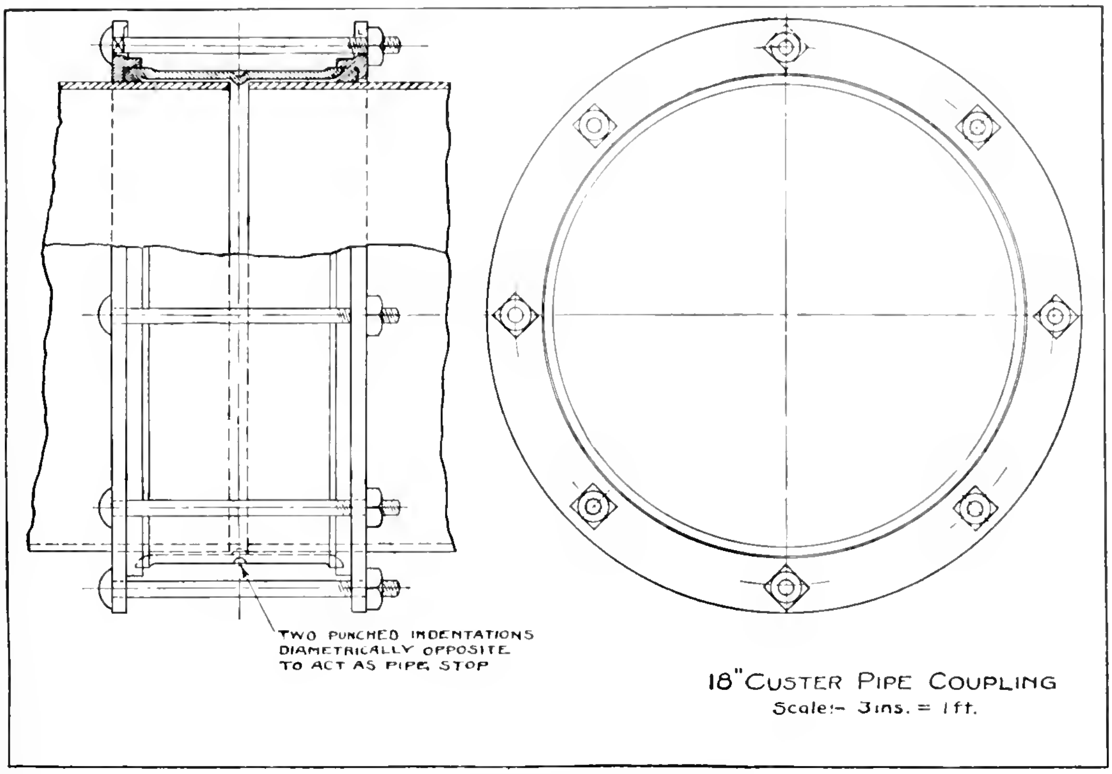

Fig. 2.—Custer Pipe Coupling.

Storage Reservoir.—The storage reservoir at Moose Jaw has a capacity of 2,000,000 gallons. It is rectangular in plan and is divided transversely by a partition into two equal parts. The 18-inch gravity supply main from Caron divides at a point exterior to the wall and an inlet branch goes to each half. Each branch is equipped with a Mason, float-operated, balanced valve, which controls the admission of water. Except at such times as the demand of the city services exceeds the capacity of the gravity supply, this arrangement will insure a full reservoir always. The reservoir is of reinforced concrete throughout, the floor having a thickness of 10 inches. The exterior walls consist of panels 18 feet high spanning between counterforts spaced 9 feet on centres. The partition wall is similarly constructed, except that it is designed to resist a full head of water in either direction. The roof is of the girderless type, supported on columns spaced 18 feet both ways, the slab proper having a thickness of 7½ inches. A five-ply felt and gravel covering overlies the concrete roof, and on this, in turn, a filling of two feet of earth is placed.

The Moose Jaw Pumping Station.—The Moose Jaw pumping station is of the same general style of construction as the headworks pumping station. Its equipment consists of two Canadian Böving centrifugal pumps direct connected

to two Siemens 35 h.p. motors which receive their power from the supply mains from the city's central power station. These pumps lift the water to the elevated tank, a height of upwards of 110 feet. They will ordinarily draw from the storage reservoir, but the piping arrangements will permit water to be drawn direct from the Caron gravity main. In addition to this, either pump can draw from either side of the reservoir. Finally the piping system will permit of water being fed (without pumping) from the reservoir or from the gravity main into the city's distributing system, either of which would give a moderate pressure over all of the city except the highest parts. If desired, the elevated tank may be cut out and the pumps made to discharge direct into the mains. The motors are equipped with Cutler-Hammer switches operated by a float in the elevated tank. This is intended to keep the tank practically full at all times. The pumping station is supplied with a heating boiler with circuits through the reservoir and the riser of the elevated tank to provide against unusual frost conditions.

The Elevated Tank.—The elevated tank is a steel structure of 75,000 gallons capacity, and is carried on four posts. It is provided with a riser 6 feet in diameter. The bottom is elliptical in section. The tank is provided with a mercury pressure indicating gauge and with floats operating the motor switches in the pumping station. The elevated tank, the Moose Jaw pumping station, and the storage reservoir stand in close proximity on what is practically the highest ground in the vicinity of the city.

As stated previously, the infiltration gallery, the headworks pumping station, the pressure main and the headworks reservoir were all done by day labor. The Wm. Newman Company, Limited, Maurice S. Holmes, and the Moose Jaw Construction Company, Limited, were the contractors for the laying of the gravity pipe line, the pipe itself having been supplied by the National Tube Company through the United States Steel Products Company. The storage reservoir and the Moose Jaw pumping station were constructed by the Moose Jaw Construction Company, Limited. George T. Horton, of Chicago, supplied the elevated tank. Drummond, McCall & Company supplied all valves, fittings and specials. The mechanical equipments at the headworks and Moose Jaw pumping stations were supplied by the Canadian Böving Company, Limited, and the Canadian Fairbanks-Morse Company, Limited.

At the present time the infiltration gallery is laid for only about half its contemplated length, and the system of deep wells across the valley to tap the lower supply has not been constructed. The reason for this is that it was considered best to test out the supply this winter with only part of the gallery in operation. Then, if the conditions require it, the balance of the gallery and the deep wells are to be constructed next season. It is quite likely that the present works will be extended so as to include the whole of the development originally contemplated at the headworks.

The Canadian Pacific Railway, the Canadian Northern Railway and the Grand Trunk Pacific will all be active one way or another on the southern part of Vancouver Island. Following that will be expansion further up the Island, so prospects are good.

There are differences in Vancouver over the Canadian Northern Railway agreement, which will shortly be voted on by the people. At the meeting of the board of trade on Tuesday last, a resolution was carried asking that the people vote against the proposition. It is not probable that the board of trade will be seriously heeded in this matter, for the agreement seems to be supported about the city.

COAL STORED UNDER WATER.*

For some time past the attention of those responsible for the control of large industrial and engineering concerns has been centred upon the problem of effectively storing large quantities of coal so as to avoid, or at any rate minimize the risk of spontaneous ignition, and at the same time prevent undue deterioration in quality. As has been frequently pointed out, coals of the bituminous gas-making type (i.e., coals containing about 30 per cent. of volatile matter) are usually found to be affected to a far greater extent than the less volatile steam coals. The unsatisfactory aspect of the whole question, however, is that there is no definite means by which it is possible to ascertain whether or not a certain coal is one which must be regarded with suspicion. In fact, it frequently happens that a stack of apparently harmless coal will heat up without the slightest warning. Hence the only course open to the cautious engineer is to assume that any and every class of coal is liable to ignition, and to subject each consignment—whatever its tendencies—to similar conditions of storage.

The more common method is merely to dump the coal in large stacks, at the same time observing certain well-established rules and ordinary precautions; but another plan, which, however, is seldom adopted in this country, is to submerge the whole stack in a suitable reservoir of water provided for the purpose. This system is viewed with considerable favor by American engineers, and whenever it has been adopted the additional first cost has been found to be more than balanced by the benefit gained in the form of less deterioration, and, of course, perfect freedom from fire. It was originally suggested by a dock engineer who carried out a number of experiments on pieces of coal which had been accidentally split during transference from ship to shore, and which were subsequently recovered from the river bed. This coal, part of which had probably been submerged for some considerable period, showed on analysis a surprisingly small amount of deterioration, and the same results were obtained when experiments were made with larger amounts. In some cases the dredged coal had been immersed for at least ten years, and even then it was found to have lost little of its original value; while in the case of samples immersed for about three years the deterioration was estimated to amount to less than 3 per cent. This is, of course, a remarkably low figure when compared with that for ordinary bituminous coals stacked in the open in this country, for they invariably show a decrease in value of from 5 to 8 per cent. in the course of 12 months. In more tropical countries, and in climates in which variations and extremes of temperature are abnormal, the loss is naturally very much greater. For instance, coal of the Navy type stored in Hong-kong is said to suffer to the extent of from 20 to 40 per cent. If this is the case with a steam coal, the corresponding amount of deterioration of a bituminous coal would be a somewhat serious consideration.

Advantages of Wet Storage.—If it were possible to maintain an equable and moderately low temperature throughout a coal stack there would probably be little trouble with spontaneous firing, and it is in this respect that the wet method is superior to any other. Nowadays coal stocks kept in hand by industrial concerns are in many cases far too large to be provided with shelter from the weather, and are consequently subjected to varying conditions of snow, rain, frost, and sun. When submerged, however, the material is protected more adequately than if it were housed; and, no matter what are the weather conditions, the variation in temperature of the mass will be comparatively small. It is now generally

*From Scientific Supplement of London Times.

recognized that the gases occluded in the pores of the coal—more particularly oxygen—are indirectly the cause of both heating and deterioration, and their escape should as far as possible be arrested. By immersing coal and keeping it continually sealed this condition is fulfilled, the gases being more or less confined, while little or no oxidation takes place. The breaking up of lumps and pulverization are considerably reduced, because the water forms a cushion between the various pieces, thus lessening the effect of the movement of the lumps one on another, though the better physical condition of the coal is probably due in part to absence of heat, which in itself is to a great extent the cause of the opening out and disintegration of the larger pieces.

Authorities on the question of coal storage are now generally agreed that no air-stacked heap—whether housed or in the open—should be taken to a greater height than about 20 ft., chiefly on account of the danger of the formation of "dust-pockets," which are frequently the primary cause of ignition. There is, however, no limiting depth in the case of an immersed stack, and accordingly a considerable saving of space can be effected. This, again, is a material consideration from the point of view of works lying in the centre of congested districts, where vacant spaces are limited and the price of land excessive. For instance, if 20ft. is to be the maximum height of the stack, the storage capacity is limited to between 40 and 50 tons per 10 sq. yards of ground area, and thus an acre of ground space will accommodate, at the outside, only some 20,000 tons—by no means an excessive quantity in view of the huge demands of industries such as gas-making, in which the larger works carbonize as many as 1,000 to 2,000 tons a day, and in some cases even greater quantities. By adopting the wet storage method the capacity per unit of ground area could certainly be doubled, and there is no reason why it should not be even greater.

Possible Defects.—With all its possibilities and advantages, the storage of coal under water is sure to introduce a certain number of undesirable factors, and perhaps the most serious question to be taken into account is that of expense. At present the cost of stacking coal is considered to be no more than the value of the ground upon which the coal stands, although in addition there should be reckoned the expenses of constant supervision and labor in turning over and working out suspicious parts of the heap. The expense of conveyance to and from the stack may be neglected, because it is necessary in both cases, the extra depth in the wet method being balanced by the saving of distance.

The coal reservoirs—usually constructed of reinforced concrete—must, of course, be designed with foundations varying in accordance with the proposed depth, and in the event of the latter being considerable the expense is somewhat heavily increased owing to the great pressure on the floor and side walls. A further consideration is that of pumping machinery for emptying or filling purposes.

A contingency which must not be overlooked is the possibility of sudden frost and the consequent freezing up of the reservoir to some considerable depth. It is improbable that anything of the kind would occur in this country, and in places where intense cold prevails wet storage would be unnecessary owing to the limited amount of deterioration and greater immunity from fire in such climates.

There is, however, an admirable system in vogue known as the "mixed method," according to which a supply of coal is stored in the open for immediate requirements, and the deficiencies are made good by deliveries. At the same time a certain quantity is stored in the water reservoirs, and this is set aside for use in the case of emergency only. Even should ten years elapse before an emergency arises, the coal (as previously pointed out) should be found to have deteriorated to only a very slight extent.

One of the largest reservoirs constructed for the purpose of storing coal under water is that which it was decided to erect at Stettin about two years ago. The tanks, on the banks of the River Oder, were designed to be capable of dealing with 20,000 tons. Towards the close of 1911 arrangements were also completed for storing 6,000 tons of coal in this way at the works of the Omaha Electric Light and Power Company, and a most elaborate coal handling plant was erected for working in conjunction with the tanks. In this case the tanks are comparatively shallow, their depth being 22ft., and the side walls are carried on piles owing to a treacherous stratum of quicksand. Piles at a pitch of 5ft. were also driven under the whole of the floor area and capped with square slabs of concrete, upon which the floor rests. In this way the whole of the load is brought upon the piles and none of it is upon the earth. The side walls are about 2ft. thick at the top and 4ft. 6in. at the bottom, and the concrete floor is protected from the bite of the coal "grab" by means of embedded rails.

Effects of Using Wet Coal.—When coal has been subjected to storage under water for any length of time it is usually found to be somewhat brittle and decidedly dull in appearance. But the latter effect is merely superficial, and on drying in the sun it rapidly disappears. In many cases, however, time would not permit of the coal being set aside for drying, and the consumer would be faced with the difficulty of using fuel containing a high percentage of water. For steam-raising and all firing purposes this would no doubt be of little account, but the question cannot be considered lightly when the coal is destined for gas-making purposes. It has long been a general belief—probably an exaggerated one—that if wet coal is carbonized in gas retorts the proportion of impurities will be increased and, in addition, greater quantities of the much-maligned hydrocarbon naphthalene will be evolved. Thus the storing of coal under water would be likely to meet with stout opposition from the gas engineer. However, full charges of coal (that is, charges that completely fill the retorts) are now the order of the day in the gas world, and under such conditions the moisture has practically no evil effect. At any rate, it should be found more profitable to carbonize a wet coal giving a slightly increased yield of impurities than an air-stacked coal which had lost perhaps 10 per cent. of its gas-making value.

SAFETY FIRST.

The Canadian Pacific Railway Company has ordered a sheet filled with mottoes of "safety first" propaganda for distribution. Points already emphasized by numerous safety committees are brought out, as follows:—

I will not stand in front of a moving car, or engine, to board same.

I will always respect the blue flag, because the lives of my fellow-employees depend upon it.

I will not hold on to the side of a car when passing platforms, buildings or obstructions close to the track.

I will not shove cars into a freight shed, or on team tracks, without first making sure that all men and teams are clear.

I will not kick cars into sidings, where boarding cars, or cars being loaded, or unloaded, are standing.

I will remember that it is better to let a train wait than to cause an accident.

I believe that Safety First is simply a habit and I will cultivate the habit.

The prevention of accidents is a duty I owe myself, my family, and my fellow-employees.

I will take out immediately sufficient accident and life insurance to protect myself and those dependent upon me.

MAMMOTH FLOATING DOCK.

Paralleling the increase in size and tonnage of ocean-going ships of was is the tremendous size of floating dry-dock constructed to handle them. Lately in England there was placed at Portsmouth a floating dock capable of handling the heaviest of British battleships. An interesting chat about this monster, written by S. A. Mackenzie, a pupil at Queen's Engineering Works, and printed in the Queen's Engineering Works Magazine, follows. The battleship "Monarch," which is spoken of is one of the largest and latest in the British navy. Completed in 1912, it is of 22,500 tons displacement, 27,000 I.H.P., and speed of 21 knots. It has turbine engines and a main armament of ten 13.5-inch guns.

The floating dock, constructed by Messrs. Cammell, Laird and Company, Limited, at Birkenhead, for the British government, at a cost of over a million sterling, is capable of raising a ship of 32,000 tons. It consists of a series of tanks, the total length of which is 680 feet and the breadth 150 feet. On either side two walls 15 feet wide rise to a height of 46 feet above the pontoon deck. These walls are connected by a swing bridge for use when there is no ship in dock.

Along the bottom of the tanks a line of pipes is run with a branch-piece and valve to each tank. These valves are controlled from the valve-house on deck and are worked by compressed air. The air is admitted through a cock opened by means of an electro-magnet, the current being switched on in the valve-house. A switchboard is provided on each side of the valve-house, the position of the switches corresponding to their respective tanks, while above each switch are indicators showing whether the valve is open or shut, and the level of the water in the tank.

The controller can watch the performance of the dock by means of two spirit levels set at right angles.

Placed between the sides of the walls and just below the upper deck are the compartments containing the machinery for working the dock. At each corner are two boilers, and adjoining each boiler-room two horizontal open engines, with vertical shafts which drive the 16-inch centrifugal pumps that are used for raising the dock. These are placed at the bottom of the dock. A condensing plant and fire-pumps, etc., are installed below each engine-room. Throughout the dock is a complete installation of electric light.

The dynamo-rooms are situated at about the middle of the dock on either side, and each contains two Allen 200-kw. sets, consisting of enclosed vertical engines and shunt wound continuous current dynamos. It was in connection with the erection and running of these that I was fortunate in spending several weeks on board the dock. The switchboards are arranged so that all four machines can be run in parallel for supplying current for the dock itself, and to the ship in the dock; also by means of two-way switches either machine can be connected direct to the ship. The voltage of the main generators being 225 volts, two motor-generators (one in each dynamo-room) are provided, with a range of 85 to 115 volts, for giving current to ships with lower voltages. In each dynamo-room is a motor-driven air-compressor for working the valves, pneumatic tools, etc.

On the starboard side of the dock is a large workshop containing lathes, planing, drilling, and screw-cutting machines, punching and shearing machines, while in the smith's shop is a steam-hammer and a set of rollers. The top deck on either side is provided with four steam-driven capstans and a 5-ton electrically driven crane, travelling the whole length of the deck.

On the port side, cabins and a wardroom for the accommodation of twelve men are provided; also extensive lavatories and wash places for the crews of ships in the dock.

The dock was built in a specially constructed basin having a large temporary dam, and when complete a portion of the dam was cut away, and the tide allowed to flow under the dock. Some little difficulty was experienced in getting the dock out of the basin. A high wind was blowing at the time which, catching the walls of the dock, drove it into one side of the dam, where it remained for nearly half an hour, all efforts of the tugs proving unavailing. Anxiety prevailed lest the tide should go down before the dock could be got clear. At last, with a rending of timber, the dock slowly moved forward, carrying with it about fifteen feet more of the dam. Owing to the very strong current in the Mersey it required ten tugs to convey the dock safely to the bar. Here six of the tugs left us, taking with them the men who had assisted in getting us away. We then continued our journey to Portsmouth, and next morning arrived off Holyhead.

The weather was very rough during the whole of the voyage round, but with the dock covering such a great area we could scarcely feet the motion of the sea at all. It seemed very strange to stand on the bridge and watch the tugs rolling and pitching about, while we felt as though we were on terra firma.

Coming up the English Channel the tugs were pulling at right angles to the dock nearly the whole of the time, the wind creating so much pressure on the walls that we were travelling sideways.

A cross-channel steamer seeing us in this position, and being unable to read our signals, sent a wireless message to the shore that we were in difficulties. A cruiser was sent after us from Portland, but on learning we did not require any assistance she turned back.

On arrival at Spithead, it was too windy for us to go into harbor, so we had to put to sea again, and lie off the Isle of Wight all night. Next morning, however, the wind had dropped considerably, and four dockyard tugs came out and towed us safely into Portsmouth harbor, after being eight days at sea.

During the voyage, many amusements were resorted to to pass away the time. Cricket, running and jumping afforded good exercise, while fishing was greatly indulged in, but, sad to relate, only three small mackerel were caught during the whole time we were at sea.

At Portsmouth the trials were satisfactorily carried out, the dock raising H.M.S. "Monarch."

TRADE DISPUTES SHOW DECREASES BOTH IN NUMBER AND MAGNITUDE.

There was further improvement in industrial conditions in regard to the number of trade disputes during January. At the end of the year 1912, there were seven disputes in existence of such magnitude as to affect industrial conditions and two of these were settled during January. Five new disputes occurred, a feature of which was the fact that by none of them were more than one hundred employees affected. Disputes in existence in January were twelve in number as compared with thirteen during December. The number of employees affected also showed a decrease, being 2,208 as compared with 3,850 during December. The number of working days lost during January was about 48,000, which represents a decrease of more than 18,000 as compared with the December record. There were seven disputes left unterminated at the end of the month.

REPORT OF THE TWENTY-SEVENTH ANNUAL MEETING OF THE CANADIAN SOCIETY OF CIVIL ENGINEERS

This report of the proceedings of the annual meeting of the Canadian Society of Civil Engineers, held in Montreal January 28th, 29th and 30th, 1913, is continued from the February 6th issue of The Canadian Engineer. In that issue the proceedings of Tuesday, January 28th, appeared.

On Wednesday, January 29th, during the morning, the members inspected the Montreal Steel Works at Longue Pointe.

Afternoon Session,
January 29th, 1913

THE PRESIDENT stated that they were dealing yesterday morning with the reports from the branches. He thought they had better go on with the reports of committees.

REPORTS OF COMMITTEES

Report of Committee on Establishment of Testing Laboratories

THE PRESIDENT said the first report was that on the establishment of Testing Laboratories.

MR. MACKAY, one of the members of the committee, said they had not held any meetings during the past year so far as he was aware, so there was nothing he could add to the printed report. Of course, the changes mentioned in the administration of the Department of Public Works doubtless were responsible to a very large extent for the small amount of progress made.

THE PRESIDENT asked if it was the wish of the meeting that the report be received as a progress report and adopted, and that the committee be continued as it stood?

This was carried.

Report of Committee on Educational Requirements

The next committee was that on educational requirements, of which Mr. Marceau was chairman. As he was not present the next report was taken up.

Report of the Examiners' Board

THE PRESIDENT asked Professor Mackay, as chairman of the Examiners' Board, to discuss the report.

MR. MACKAY said that although the report of the Examiners' Board was short, the Board had done a good deal of work during the time it had been organized, the last ten months. The most difficult task was to draw up a syllabus of the examinations, because they had little guidance to help them in that respect, and they were rather between two difficulties, one to set a standard that would really mean something, and the other to make that standard such that no worthy applicant should be rejected. Whether they had succeeded in accomplishing that task he did not know. They certainly had so far to their own satisfaction, but they realized the work at present was only in the experimental stage. The syllabus of the examination should be drawn up and printed, and also a complete set of examination papers, which might serve as some indication of the standard required in Canada. Also a set of examination papers should be printed on the subjects for which candidates presented themselves at the second examination. Two examinations were held. As there was but little time to prepare for those examinations, only a small number of candidates came up this year, most of whom, he thought, succeeded in passing. The committee had also been called upon to examine a large number of certificates presented by men who, although they were not under the strict regulation exempt from examination, still were able to present certificates of educational acquirements which might reasonably be looked into and accepted. Some of these, of course, were accepted and some rejected, and that involved a considerable amount of work. He was sure all the members of the Board would be very glad to receive any suggestions to guide them in continuing the work. It was to the benefit of the Society that they should do so.

MR. SKAIFE thought this committee was a very important one, and they should make it as prominent as possible. One good reason is that if this Society was recognized as an educational Society they ought to be able to secure exemption from taxes, which amount to over $800 a year. He wrote to the committee about that some time ago. When the Government of Quebec regards the Society as an institution of that kind, the City Council would fall into line. He knew it had been the policy all along to encourage education in the province.

THE PRESIDENT thought the Society ought to be considered as an educational institution. They were doing their best to elevate the standard of the engineering profession.

The resolution for the adoption of the report was then put and carried.

Report of the Quebec Branch

THE PRESIDENT then took up the report of the Quebec branch, which had been passed over a few minutes ago because no one was ready.

The report was then read by the Secretary.

MR. DODWELL moved that the report be received and filed.

Carried.

Report of the Canadian Committee of the International Electro-Technical Commission

THE PRESIDENT said the next report was that of the Committee of the International Electrotechnical Commission, and called on Dr. Herdt.

Dr. Herdt said a few words might be added to this report in order that the members might know exactly what was being done.

The Canadian Committee was appointed by the Council of this Society to join with the committees appointed by practically all the great countries of the world to form an Electrotechnical Commission, whose duty is to standardize electrical symbols and also to go into the matter of the standardization of electrical machinery. These committees

appoint delegates to annual meetings which are held in different parts of the world. The last meeting was held at Turin, Italy; the next will be held at Zurich, Switzerland.

The Society had a delegate sent from Canada to the last annual meeting. The recommendations made by the different committees were considered, and some of them amended, others approved. As might be understood, such work is, of course, very slow, a great deal of it having to be done by correspondence, as no recommendation can be carried before it has been submitted to the different committees. Publications have been issued by the commission, which had to be submitted to the different committees for approval.

The largest amount of work had been done in relation to the standardization of symbols. It was very difficult in taking up a text book on electrical matters to understand exactly what the different symbols used exactly meant. The committees have practically settled on uniform symbols to denote the various terms in electrical machinery and electrical engineering.

Several committees have been appointed by the different countries in regard to electrical machinery. This is with a view of standardizing principally the rating of electrical machinery, so that when a machine is rated at a certain kilowatt capacity, or horse power, it will have the same meaning throughout the world. The Society committee has been doing considerable work by meeting either in Ottawa or Montreal, getting members together, and making recommendations.

Dr. Herdt hoped this report would be carried by the meeting, and that the members of the committee would be allowed to continue this work for the succeeding year. In that way they would keep in touch with the subject, which was of great importance to Canada, as this country is becoming a large centre for electrical machinery and provides unlimited scope for electrical engineering. (Applause.)

THE PRESIDENT asked if it was the pleasure of the meeting that this report be received and adopted, and the committee continued?

MR. VAUGHAN asked if it would not be a good scheme to reconsider the matter of appointing committees by the general meeting? Why not have them appointed by the council, subject to any suggestions the general meeting wanted to make? They were continuing committees from year to year, and after action was taken by the general meeting the council was powerless to add to a committee, change it, or reach it in any way.

MR. MONSARRAT thought Mr. Vaughan's remarks were well chosen. For instance, in some committees the members were very far spread and during the year they did nothing. In the meantime the council had no power to make any changes. It seemed to him the council ought to have such power so they could make any necessary changes recommended by the Chairman.

DR. HERDT said it was doubtful whether the Canadian Society of Civil Engineers had any jurisdiction over this work. The International Electrotechnical Commission was appointed in England some years ago, and it was understood at that time that the members of these different committees would be appointed by the technical societies and the manufacturing interests of each country, and that if they did not appoint these committees the government would do so. He was present at the first meeting of this commission in London, England, three years ago. He was a member of the special committee which had to draft out rules and regulations governing that commission, and he had pointed out to the different members present, that in Canada at that time they had only one engineering society, and that the Canadian Society of Civil Engineers was really a parent society embracing all engineers, that is, civil, electrical and mechanical. The Dominion Government the first year naturally stepped in and appointed a committee, and practically up to last year sustained it. It had since been continued with funds obtained from individuals and from the commission. They had to send in each year $200 to the Secretary's office in London, and looked after their own expenses. The Canadian Society of Civil Engineers subscribed last year $100, which was only a small portion of the expense they had had to carry themselves. The Canadian manufacturers had subscribed liberally to this work, and individually they had subscribed.

This committee was a very representative one. It consisted, besides himself, of Mr. Higman, who represented the Dominion Government; Dr. Barnes, who represented McGill University; Mr. L. W. Gill, who represented Queen's; Mr. T. R. Roseburgh, who represented Toronto; Mr. Duff, who represented the West; Mr. Kynoch, who represented the Canadian General Electric Company; Mr. Murphy was the electrical adviser of the Board of Railway Commissioners, and Mr. Lambe, the secretary, was also at the head office in Ottawa. So a number of these gentlemen might not be members of the Society of Civil Engineers, and there was nothing in the constitution of this commission to say that they must be members.

He felt very strongly that unless this Society continued their support, morally and otherwise, to this work the committee would have to look elsewhere for assistance. Personally, he had been for a number of years asked by the American Electrical Engineers to join in the formation in Canada of a branch of the American Institute of Electrical Engineers. He had stood against that, and, as they knew, there was no branch of the American Institute in Montreal at the present time, because he thought the Canadian Society should cover the whole engineering field. (Hear, hear.)

When it was discussed as to who should vote, it was decided that each country should have one vote, and Canada was the only country which has a vote outside of great countries like France, England, Norway and Sweden. Thus they were recognized as practically being autonomous, and their importance in this branch of engineering acknowledged.

Therefore he would ask that at this meeting the Society continue its support to this committee, as the work they were trying to do with the other countries was of very great national importance. (Applause.)

MR. MONSARRAT said what he thought was intended by Mr. Vaughan's remarks, and what he intended, was not that they should not support this particular committee, but that the council might have power to change committees on the Chairman's recommendation, and if the Chairman was satisfied with his committee he would not recommend any changes. This was merely giving the council such power as was necessary, so that instead of carrying a lot of dead wood, action might be taken from time to time to strengthen any committee.

THE PRESIDENT said this was a special committee over which they did not have very much jurisdiction. He did not think there should be any change made in this committee. In fact, they had not power to make any change in it.

MR. MURDOCK moved that that report be accepted and the committee continued. It appeared to him the last speaker's argument was a very strong one for leaving the committee alone.

Duly seconded and carried.

MR. MOUNTAIN replying to Mr. Monsarrat's question, said at the present moment all committees had power to add to their number. If they found there was dead wood on,

they need not strike such members off, but there was power to add new members.

THE PRESIDENT said the next committee was that on Specification for Steel Bridges, of which Mr. Monsarrat was Chairman.

Report of Committee on Specification for Steel Bridges

MR. VAUGHAN moved that the report be received and a committee appointed by the council to continue the work.

MR. MOUNTAIN wanted to know from this committee if it was their proposal to make the specification of the Canadian Society of Civil Engineers a standard for steel bridges.

THE PRESIDENT said that was the proposal.

MR. MOUNTAIN asked if this meant that the specification for fixed spans was adopted.

MR. MONSARRAT said yes.

MR. MOUNTAIN said on this committee were the bridge engineers of the Canadian Pacific, the Grand Trunk Pacific and the Grand Trunk Railways, and the Chief Engineer of the Department of Railways and Canals. All those men were working under more or less different specifications, and his enquiry was this: If in signing this as members they have agreed, or will agree, to make the standard of the Canadian Society of Civil Engineers their standard? He would tell them why. The Canadian Northern Bridge Engineer, who was present, Mr. Chapman, was not on this committee. Most of these railroads from time to time have branches that have been, or are, subsidized roads. Under their contract with the government they are obliged to build their bridges to the specification of the Department of Railways and Canals. In course of time those bridges are altered, not likely because they have become decayed or rotted out, but in most cases on account of heavier motive power being used. Then these roads come back with another specification on which to build these bridges. All bridges built by all these roads mentioned have got to come before the Dominion Railway Board in his (Mr. Mountain's) department. To-day he was dealing with a specification gotten up by the Department of Railways and Canals, which the Board accepts; he was dealing with the American Engineers' Maintenance of Way specification for the Grand Trunk Railway; he was dealing with the Dominion Government specification for the Grand Trunk Pacific; he was dealing with the Canadian Pacific's own specification for the C.P.R.; and the Michigan Central have got another. His idea was this, that if the Canadian Society of Civil Engineers, with these men on that committee, feel that they can see their way to making one standard specification for steel bridges, he was prepared to recommend to his Board the adoption of that standard, and bridges will be passed on that standard, and on that standard only. He might say that Mr. Uniacke, the bridge engineer of the National Transcontinental, is also on that committee. He would like to get the views of those gentleman on that question.

MR. MONSARRAT said that was one of the principal ideas they had in drafting this specification, to try and get some uniformity, and he thought the gentlemen who are on this committee would agree with Mr. Mountain's wishes, that they will adopt that as their standard, with possibly a few changes in some minor paragraphs. It was very hard to get a specification that everybody agrees to exactly all the way through, but the general specification could be adopted, and he had reason to believe that this specification would also be adopted by the Department of Railways and Canals, and so make for uniform practice throughout the country.

MR. SULLIVAN said he could not agree for his company. It would be the most unfortunate thing that ever happened to the railways and the public of Canada that such a policy should be carried out. Write up that specification as a standard and nobody had authority to change it. If the Board of Railway Commissioners make a standard, everybody has to stick to it. It would be the beginning of retrogression. He was chairman of a committee that has done some work, but if this Society was going to vote that that specification be made a standard in any department of the government, and compel people to adhere to it, he would vote against it. This Society's recommendations should be educational in form, that is, recommend this as good practice; but every member, student and engineer in the country should have the right and privilege of varying from that specification to suit particular conditions. He would never believe anything else.

MR. DUGGAN said as a member of that committee, he was very much in accord with Mr. Sullivan. All these bridge engineers are not of one mind necessarily as to what is the best practice. The committee got all their opinions together and brought them as far as possible into unison, and put up what necessarily is a sort of compromise specification as being the average opinion of all the men who are more or less expert in that work. As Mr. Sullivan said, they simply put that forward as representing what they thought was the best practice. He thought the Department of Railways and Canals should adopt this specification, but there was no reason why every railroad should also adopt the same specification.

MR. MOUNTAN said he had not made himself clear. No railroad gets a subsidy unless it builds its bridges in accordance with the standard laid down by the Department of Railways and Canals.

MR. DUGGAN corrected him and said, up to that standard.

MR. MOUNTAIN said whether it was the Canadian Pacific, or the Grand Trunk Pacific, they were building to the Department of Railways and Canals specification. The Grand Trunk Pacific are obliged to under their contract with the government. This is what occurs. A railroad is located and plans are submitted to the Railway Board for approval. The company builds its bridges under the American Engineering Maintenance of Way Association specification. The Chief Engineer in presenting the plans states what they are. He is asked if it is a subsidized road. He says, "Yes." He is asked if he has submitted those to the Department of Railways and Canals. He says "No," because until the plans go through your Board they cannot go to them, you fix the location. They are passed under their own standard, say the Canadian Pacific Railway standard. Then they submit under the subsidy contract plans and specifications for those bridges, and they are obliged to conform to the department's specifications.

Three years ago this Society made a standard for water pipes, sewers, etc. (Mr. Ker, City Engineer of Ottawa, was chairman of the committee), for putting crossings under railway tracks. That standard was adopted by the Railway Board and put in their rules and regulations. Now an order simply goes out that the pipes shall be carried under the railway in accordance with the standard of the Canadian Society of Civil Engineers. It has remained so, and it is lived up to.

THE PRESIDENT said that, of course, the Society cannot in any way control the different railways. The mere fact that the Bridge Engineer of each railway company was on this committee does not commit his railroad.

MR. MONSARRAT said that he did not see why it would be really worse to have this specification than the one the government has at present.

MR. SULLIVAN said the government specification was a general specification; this goes very much into detail.

MR. DUGGAN said he was afraid that Mr. Sullivan did not fully understand this specification. This was mostly on the same lines as the Canadian Pacific specification, the Grand Trunk specification, the American Maintenance of Way specification, and the specification of the Dominion Government. There was some difference in practice in matters of loading. This specification, as drawn up, allowed for choice of loading, etc., just exactly as did the Maintenance of Way and the Grand Trunk specifications, and to a certain extent the C.P.R.'s specification. There were some minor changes, but it was simply a matter of codifying the best existing specifications of the day, and with a view to revision of the government specification, which was a little antiquated. He did not think the government would tread on the toes of any railway if it adopted this specification as the standard of good practice, and left the railways free to make it better if they saw fit; but this ought to be the lowest standard.

MR. SULLIVAN said he was speaking in general terms on general principles. The principle of this Society in adopting a certain specification and urging that it be adopted by the railways and by the government was wrong. He had not read the specification, and possibly it was so general that it might not do any harm, but the principle was wrong.

MR. MONSARRAT said with regard to using wooden ties, or a steel floor, or a ballasted floor, there was nothing in the specification to prevent it.

MR. SULLIVAN said he was simply trying to bring out the point that the attempt to get all railways to adopt one specification and agree to it without change was wrong in principle. He belonged to the Maintenance of Way Engineers' Association, and he presumed that 99 per cent. of the work that was done in the grading and building of railroads was in accordance generally with the Association's specification, but he did not think three per cent. of the railroads had adopted that in its entirety without changes. The principle was right to have a specification that would tend to uniformity, but to make that the only standard was wrong.

MR. KENNEDY said they could not pretend to legislate for the whole country, and the putting out of this specification did not tie up anybody.

THE PRESIDENT said in putting out this specification they could only put it forward as the Canadian Society's specification and they could not in any way make any pretense of saying to the Canadian Pacific, the Grand Trunk, or any other road, that that must be their specification. They could adopt any specification. On the other hand, in regard to the Railway Commission, it seemed to him that they must have something to guide them in dealing with the railways, and the better the specification is the better for the railways; that is, the more perfect it is in its get-up the better it is for the railways. This specification has certainly been gotten up by the best bridge engineers in the country, and it seemed to him, from a Railway Commission standpoint, that it would be better they should adopt it, if it were a satisfactory one, (as it should be under the conditions) than that the Railway Commission should appoint some engineer of their own to draw up a specification. The mere fact that this specification was adopted by the Railway Commission could not make it a standard for the railways, although in a certain sense, if it is the Commission's standard the railways must live up to it, although they may go beyond. Therefore, it seemed to him that Mr. Sullivan was hardly clear in his point. The Railway Commission had an undoubted right to get up a specification if they so desire, and they have the power to enforce it on the railways. His point was this, that if the Railway Commission were going to have a specification, it was better in the interests of all concerned that they have a specification gotten up by this very eminent body of engineers than that they adopt one made by themselves, that they will get better results from this body than from any other body in Canada. They had no power to enforce it on the Railway Commission, but if they wished to adopt it there was no power that can prevent them.

The motion that the report be adopted, and that a committee to carry on the work be appointed by the Council, was put and carried.

Report of the Committee on Conservation.

MR. WHITE did not think any extended remarks were necessary in regard to that.

The matter was brought to the attention of the committee, as would be seen in the initial paragraph, by a letter from Mr. Sauder, dealing with the question of the organization and provision of the necessary staff to gauge streams in Canada. The preliminary portion of the report was somewhat of an academic nature, and then followed a brief statement of what had already been done in the various provinces of Canada.

In Nova Scotia some work had been done by the Commission of Conservation. In New Brunswick the Commission had also done some work, and also the St. John River Commission. In Quebec they had gauges at some of the canals, and gauging had also been done by private concerns. In Ontario they had the Hydro-Electric Commission and also the Department of the Interior, the International Joint Commission, and the Department of Public Works. In the Northwest all the work had been done by two branches, the Department of the Interior supplemented by the Department of Public Works. In British Columbia the work was being done by the Conservation Commission.

He had just run briefly over the work that was being done in the various provinces to show the diverse organizations that were engaged upon this work, and anyone who appreciated the value of this work could see at a glance that it was far better that this work should be concentrated in some shape or form. The committee made a few recommendations, which would be found at the end.

The recommendations in brief were that it would be advisable that this work be concentrated in some shape or form, and that preferably some Dominion organization should undertake the work. But the committee did not make that a recommendation concerning action by the Society. He understood from Mr. Mitchell, who was also a member of the committee, that he had a motion to make in connection with that.

MR. MITCHELL said what he had to propose was not with reference to the continuation of the work of the committee. He thought that should proceed. He thought it was the desire of all the members that the committee's work should continue, because they were charged with the state question of conservation. What the burden of this report had reference to was stream measurement. As they all knew, that was one of the most important features they had to deal with in Canada at the present time, particularly in reference to the development of the country, and as was very evident from the report, and as had been pointed out by Mr. White, there was great confusion in the methods of investigation of stream measure throughout Canada. There were many bodies which were carrying on those investigations, and there was comparatively little uniformity in doing the work,

while the results were put in various forms and kept in various places.

He had a proposal to make which was entirely separate from the question of the continuation of this committee, and it was that the question of stream measurement be taken up by the Council of the Society directly as representing this Society, and that an effort be made to interest the various Government Departments of the Dominion and the Provinces, looking towards co-ordination of these various investigations. He thought it was the place of the Council of the Society to initiate this, rather than that of a Committee of the Society. The Council was a more stable element, and was perhaps in many ways better able to carry on this work than a Committee which was spread from coast to coast and of such a character that the work would fall on two or three members of the Committee. Consequently he presented this motion:—

Whereas this Society is of the opinion that it would be to the general advantage of Canada if a comprehensive system of hydrographic surveys was organized and prosecuted by some central body, with special reference to stream measurement;

Be it resolved that the Council of this Society be directed to initiate with the proper officers of the Dominion Government and the various Provincial Governments a proposal looking to the co-ordination of all stream measurement investigations which are now being carried on by the several Dominion and Provincial Government departments in various regions of the country, with the ultimate object of consolidating and continuing such investigations under some central body.

It was the desire not to specify how this could be done, or what that central body might be, but he thought it would be much to the credit of this Society, and it would be a very fruitful piece of work to the country, if this Society could initiate some movement which would co-ordinate this work into some commission or some department of the government. It was not for the Society to say, but it was for the Council to say if some such arrangement could not be made.

MR. WHITE said, in reference to Mr. Mitchell's remarks, he wanted to make clear what he intended to say at the outset. The Commission of Conservation had done some work in this connection, but it was done very much against his will, and the commission will not do any work of this character which it can induce any other organization to undertake. It must be taken up in practice by some Department of the Government; that was a matter of course. The Commission of Conservation could not undertake this work. He took this opportunity to emphasize this, otherwise someone present might think that because of his connection with the Commission he wanted this resolution passed.

MR. McCOLL seconded Mr. Mitchell's motion.

The motion was then put and carried.

The other motion, that this report be adopted and the committee continued, was adopted unanimously.

MR. MITCHELL moved that two additional names be added to the committee, namely, Mr. J. B. Challies, superintendent of water powers in the Department of the Interior, and Mr. P. M. Sauder, the chief hydrographer of the Irrigation Branch of the same Department.

Seconded.

MR. OLIVER moved an amendment to the motion that these names be sent on to the committee, with a recommendation that they be added to the committee.

MR. MITCHELL, with the assent of his seconder, withdrew his motion in favor of the amendment proposed by Mr. Oliver.

THE PRESIDENT said that this motion was now in the form of a suggestion to the committee that they add those two names to the membership.

Carried.

Then the motion that this report be received and adopted and the committee continued was carried.

THE PRESIDENT then said that in addition to these reports a number of the committees had not reported at all. Two committees did report, but not in time, namely, the Roadbed and Ballasting and the Good Roads Committees. These are specifications rather, and they have not been sent to the members, so that they are not in a position for this meeting to act upon them.

There were also no reports from the Committees on Railway Ties, Transportation Routes, Rail Fastenings and Tie Plates, Cement Specifications and Sewage Disposal.
